CHAPTER 1 GENERAL

Section 1 REQUIREMENTS FOR CLASSIFICATION

1.1.1 Conditions of classification for machinery installations

1.1.1.1 Main propulsion and auxiliary machinery installations together with their associated equipment, boilers, pressure vessels, pumping and piping systems, and gearing fitted in ships are to comply with the relevant requirements prescribed in this PART.

1.1.1.2 For the requirements for machinery installations of small ships and ships in restricted service, reference is made to the provisions in Chapter 16 of this PART and Chapter 3 of PART TEN.

1.1.1.3 In addition, the machinery installations are to comply with the applicable requirements of PART ONE of the Rules.

1.1.2 Class notations

1.1.2.1 For the specific class notations of ships, reference is made to the relevant provisions in Chapter 2, PART ONE of the Rules.

1.1.3 Plans and documents

1.1.3.1 Prior to the commencement of ship construction, plans and documents as listed in the respective Chapters of this PART are to be submitted for approval. Other plans and documents may be required to be submitted as deemed necessary for individual cases.

1.1.3.2 Any major alterations to basic design, materials or other aspects of the approved plans are to be re-submitted to ISC for approval.

1.1.3.3 For products approved by ISC, the submission of such plans and detailed information are not necessary.

1.1.4 Product survey

1.1.4.1 For the certification requirements and product survey of machinery installations, reference is made to the relevant provisions in Chapter 3, PART ONE of the Rules.

Section 2 GENERAL PROVISIONS

1.2.1 Ambient conditions

1.2.1.1 The main and auxiliary engines, shafting and machinery equipment essential to classification are to be so designed, type-selected and arranged as to ensure normal operation under the inclination conditions as shown in Table 1.2.1.1. Considering the type, size and service conditions of the ship, smaller angles of inclination may be permitted.

Angle of inclination of ships **Table 1.2.1.1**

Installations and equipment	Angle of inclination① (º)			
	Athwartships		Fore-and-aft	
	static	dynamic	static	dynamic
Main and auxiliary machinery	15	22.5	5②	7.5
Safety equipment: e.g. emergency power installations, emergency fire pumps and their device	22.5③	22.5③	10	10

Notes: ① Athwartships and fore-and-aft inclinations may occur simultaneously.

② Where the length of the ship exceeds 100 m, the fore-and-aft static angle of inclination may be taken as $500/L$ degrees, where L = length of the ship, in m.

③ For ships carrying liquefied gases and chemicals, the emergency source of electrical power is also to remain operable with the ship being flooded to a final athwartship inclination up to a maximum of 30°.

1.2.1.2 The machinery installations relevant to classification of ships are to be so designed and arranged as to ensure normal operation under the ambient temperature conditions as shown in Table 1.2.1.2.

For ships in restricted service, ambient temperature may be taken according to the actual condition of

navigation area.

Ambient temperature **Table 1.2.1.2**

Environment	Location	Temperature range (℃)
Air	In enclosed spaces	0 to 45
	Within specific space or on machinery installations	According to actual temperature of specific space or equipment
	On the open deck	-25 to 45
Seawater	All positions	32

1.2.1.3 For the purpose of determining the rating of main and auxiliary reciprocating internal combustion engines, the following ambient reference conditions apply to ships for unrestricted service:

Total barometric pressure 0.1 MPa
Air temperature 45℃
Relative humidity 60%
Sea water temperature (charge air coolant-inlet) 32℃

The engine manufacturers are not expected to provide simulated ambient reference conditions at a test bed.

1.2.1.4 In the case of ships for restricted service, the rating is to be suitable for the temperature conditions associated with the geographical limits of the restricted service.

1.2.2 Vibration

1.2.2.1 The propulsion installations are to be so designed, constructed and installed that any mode of their vibrations is not to cause undue stresses in them in the normal operating ranges.

1.2.3 Strengthening for navigation in ice

1.2.3.1 For ships navigating in ice and granted relevant additional notations, their main propulsion machinery and auxiliary equipment are to comply with the provisions of Chapter 14 of this PART.

1.2.4 Astern power

1.2.4.1 In order to maintain sufficient manoeuvrability and secure control of the ship in all normal circumstances, the main propulsion machinery is to be capable of reversing the direction of thrust so as to bring the ship to rest from the maximum service speed. The main propulsion machinery is to be capable of maintaining in free route astern at least 70% of the ahead revolution.

1.2.4.2 Where steam turbines are used for main propulsion, they are to be capable of maintaining in free route astern at least 70% of the ahead revolution for a period of at least 15 min. The astern trial is to be limited to 30 min or in accordance with manufacturer's recommendation to avoid overheating of the turbine due to the effects of "windage" and friction.

1.2.4.3 For the main propulsion systems with reversing gears, controllable pitch propellers or electric propeller drive, running astern is not to lead to the overload of propulsion machinery.

1.2.4.4 Main propulsion systems are to undergo tests to demonstrate the astern response characteristics. The tests are to be carried out at least over the manoeuvring range of the propulsion system and from all control positions. A test plan is to be provided by the yard and accepted by the surveyor. If specific operational characteristics have been defined by the manufacturer these are to be included in the test plan[①].

1.2.4.5 The reversing characteristics of the propulsion plant, including the blade pitch control system of controllable pitch propellers, are to be demonstrated and recorded during trials[②].

1.2.5 Overload power

1.2.5.1 Prime movers of main engines and electric generators are to be capable of running at an overload power corresponding to 110% of its rated power.

1.2.6 Dead ship starting

1.2.6.1 Ship's machinery is to be so arranged that it can be brought into operation from the dead ship condition using only the facilities available on board without external aid.

---

① This paragraph applies to:
(1) ships contracted for construction on or after 1 July 2018.
(2) ships other than those specified in the preceding (1) on which astern testing is carried out in accordance with 5.9.4.10, Chapter 5, PART ONE of the Rules on or after 1 July 2018.

② Same as ① above.

Dead ship condition is to be understood to mean a condition under which the main propulsion plant, boilers and auxiliaries are not in operation and in restoring the propulsion, no stored energy for starting and operating the propulsion plant, the main source of electrical power and other essential auxiliaries is assumed to be available.
Where the emergency source of power is an emergency generator which complies with 9.5.3 of this PART and 2.2.1.6 of PART FOUR of the Rules, this generator may be used for restoring operation of the main propulsion plant, boilers and auxiliaries where any power supplies necessary for engine operation are also protected to a similar level as the starting arrangements.
Where there is no emergency generator installed or an emergency generator does not comply with the above-mentioned requirements, the arrangements for bringing main and auxiliary machinery into operation are to be such that the initial charge of starting air or initial electrical power and any power supplies for engine operation can be developed on board ship without external aid. If for this purpose an emergency air compressor or an electric generator is required, these units are to be powered by a hand-starting oil engine or a hand-operated compressor.
The arrangements for bringing main and auxiliary machinery into operation are to have capacity such that the starting energy and any power supplies for engine operation are available within 30 min of a dead ship condition. For steam main propulsion unit, 30 min means time from dead ship condition to successful ignition of first main boiler.

1.2.7 Automation of machinery installations

1.2.7.1 Automatioin for machinery installations is to comply with the relevant requirements of PART SEVEN of the Rules.

1.2.8 Materials

1.2.8.1 The materials used in the construction of main components for main propulsion and auxiliary machinery installations and propulsion shafting systems, boilers and pressure vessels are to be in compliance with the relevant requirements of ISC Rules for Materials and Welding.

1.2.8.2 For all ships, new installation of materials which contain asbestos are prohibited.

1.2.9 Fuel

1.2.9.1 The flash point (closed cup test) of oil fuel for the main propulsion machinery and prime movers to drive generators or boilers are, in general, not to be less than 60℃ For the prime movers of emergency generators, oil fuel having a flash point of not less than 43℃ is permissible.

1.2.9.2 The use of oil fuel having a flashpoint of less than 60℃ but not less than 43℃ may be permitted (e.g. for feeding the emergency fire pump's engines and the auxiliary machines which are not located in the machinery spaces of category A) subject to the following:

(1) fuel oil tanks except those arranged in double bottom compartments are to be located outside of machinery spaces of category A;

(2) provision for the measurement of oil temperature are to be provided on the suction pipe of the oil fuel pump;

(3) stop valves and/or cocks are provided on the inlet side and outlet side of the oil fuel strainers;

(4) pipe joints of welded construction or of circular cone type or spherical type union joint are to be applied as much as possible;

(5) the whole fuel system is to be located outside the machinery spaces of category A;

(6) the arrangement of fuel oil tank is to comply with the requirements of 3.2.1.5(1)-(5) of Chapter 3 of PART SIX of the Rules.

1.2.9.3 In cargo ships the use of fuel having a lower flashpoint than 43℃ may be permitted provided that such fuel is not stored in any machinery space and the arrangement for the complete installation has been submitted for approval.

1.2.9.4 Ships using distillates with a sulphur content not more than 0.10% m/m are to comply with the relevant requirements of this PART and in addition, the requirements of ISC Guidelines for Use of Low Sulphur Distillate Fuels in Ships.

1.2.10 Emission treatment

1.2.10.1 Ships installed with exhaust gas cleaning systems (hereinafter referred to as the EGC systems) for reduction of SO_x emission from fuel oil combustion units are, in addition to the relevant provisions of this PART, to comply with the requirements of ISC Guidelines for Testing and Survey of Exhaust Gas Cleaning Systems and Guidelines for Design and Installation of Exhaust Gas Cleaning Systems.

1.2.10.2 Ships installed with selective catalytic reduction systems (hereinafter referred to as the SCR

systems) for reduction of NO_x emission from diesel engines are, in addition to the relevant provisions of this PART, to comply with the requirements of ISC Guidelines for Approval and Survey of Selective Catalytic Reduction (SCR) systems and Guidelines for Application of Selective Catalytic Reduction (SCR) Systems Onboard Ships.

1.2.10.3 Ships installed with exhaust gas recirculation systems (hereinafter referred to as the EGR systems) and related auxiliary systems for reduction of NOx emission from diesel engines are, in addition to the relevant provisions of this Part, to comply with the requirements of ISC Guidelines for Application of Exhaust Gas Recirculation Systems onboard Ships.

1.2.11 Clean energy and power

1.2.11.1 Ships other than liquefied gas carriers using natural gas as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of the Rules for Natural Gas Fuelled Ships.

1.2.11.2 Liquefied gas carriers using natural gas as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of the Guidelines for Design and Installation of Gas Fuel Engine Systems of Liquefied Gas Carriers.

1.2.11.3 Liquefied gas carriers using liquefied gas other than natural gas as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of 16.9, Chapter 16, PART THREE of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

1.2.11.4 Ships using methyl/ethyl as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of the Guidelines for Ships Using Methanol/Ethanol Fuel.

1.2.11.5 Ships using biodiesel fuel or the mixture of biodiesel and regular fuel as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of Pt. 3 of the Guidelines for Ships Using Alternative Fuel.

1.2.11.6 Ships provided with the fuel cell power system are, in addition to the relevant provisions of this PART, to comply with relevant requirements of Pt. 2 of the Guidelines for Ships Using Alternative Fuel.

1.2.12 Trials

1.2.12.1 The mooring and sea trials for machinery installations are to be carried out in accordance with the relevant provisions of the Rules and the approved test programs.

On completion of the trials, corresponding technical documents and trial reports are to be furnished by the shipyard.

Section 3 ARRANGEMENT

1.3.1 Means of escape

1.3.1.1 Means of escape in machinery spaces are to comply with the requirements specified in PART SIX of the Rules.

1.3.2 Boiler arrangement

1.3.2.1 Where boilers are located in machinery spaces on tween-decks and the boiler rooms are not separated from the machinery spaces by watertight bulkheads, the tween-decks are to be provided with coamings at least 200 mm in height to prevent the oily water that might leak from spreading and dropping to the lower level. This area may be drained to the bilges. The drain tank is not to form part of an overflow system.

1.3.2.2 The clearance between boilers and fuel oil tank boundaries is not to be less than that specified in Table 1.3.2.2.

The clearance between boilers and fuel oil tank boundaries (mm) Table 1.3.2.2

		Top plate of double-bottom fuel oil tank	Fuel oil bulkhead
Water-tube boiler	Outer wall	—	450
	Bottom	600	—
Fire-tube boiler	End plate	—	600
	Bottom	450	—

1.3.3 Skylights of machinery casings

1.3.3.1 Skylights located in machinery spaces of category A are to be of steel and are not to contain glass panels. Suitable arrangements are to be made to permit the release of smoke in the event of fire, from the

space to be protected.

1.3.4 Ventilation

1.3.4.1 Machinery spaces are to be adequately ventilated so as to ensure that when machinery or boilers therein are operating at full power in all weather conditions including heavy weather, an adequate supply of air is maintained to the spaces for the safety and comfort of personnel and the operation of the machinery.

1.3.4.2 All spaces, where flammable or toxic gases or vapors may accumulate, are to be provided with adequate ventilation.

1.3.5 Position of emergency equipment on passenger ships

1.3.5.1 Emergency sources of electrical power, fire pumps, bilge pumps except those specifically serving the spaces forward of the collision bulkhead, any fixed fire-extinguishing system required in PART SIX of the Rules and other emergency installations which are essential for the safety of the ship, except anchor windlasses, are not to be installed forward of the collision bulkhead.

1.3.6 Protection

1.3.6.1 In places where the working of machinery and equipment may cause injuries to the operating personnel, handrails, protecting casings or screens are to be provided.

1.3.6.2 Placards or labels are to be provided for illustrating the correct procedures of operation, so as to avoid any mistakes in the operation or change-over of the machinery or systems.

1.3.6.3 All surfaces of machinery and pipes where the hot surfaces may injure personnel are to be protected by handrails or shields. Where the surface temperature may exceed 220℃, they are to be effectively shielded to prevent ignition caused by flammable liquids. Where the insulation covering these surfaces is oil-absorbing or previous to oil, such insulation is to be encased in steel or equivalent.

1.3.7 Communication

1.3.7.1 At least two independent means are to be provided for communicating orders from the navigating bridge to the position in the machinery space or in the control room from which the engines are normally controlled: one of these is to be an engine-room telegraph which provides visual indication of the orders and responses both in the machinery space and in the navigation bridge. Appropriate means of communication is to be provided from the navigation bridge and the engine-room to any other positions from which the speed of direction of thrust of the propellers may be controlled.

1.3.8 Accessibility

1.3.8.1 Accessibility, for the purposes of control, maintenance, inspection and repair of various machinery and equipment, is to be provided in machinery and boiler spaces.

1.3.9 Stuffing boxes for shaftings

1.3.9.1 Stuffing boxes are to be fitted on the watertight bulkhead of the engine room where the shafts pass through. They are to be so arranged as to be convenient for tightening and renewing the packings from the engine room side. The fore sealing ends of the stern tubes as well as the plummer blocks are to be easily accessible for maintenance.

1.3.10 Earthing

1.3.10.1 Suitable earthing arrangements are to be provided to prevent excessive electrical potential difference between the crankshaft/shafting of main propulsion diesel engines and hull.

CHAPTER 2 PUMPING AND PIPING SYSTEMS

Section 1 GENERAL PROVISIONS

2.1.1 General requirements

2.1.1.1 Unless otherwise stated, this Chapter applies to piping systems of all ships. Chemical cargo piping, chemical process piping, liquefied gases cargo piping and liquefied gases process piping are to comply with relevant requirements in ISC Rules for Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk and ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk respectively.

2.1.1.2 The certification requirements and product survey of pumps, pipes, valves and fittings in piping systems are to comply with the relevant requirements specified in Chapter 3 of PART ONE of the Rules.

2.1.2 Plans and documents

2.1.2.1 For all ships, the following plans and documents are to be submitted for approval:

(1) arrangement of machinery and boiler spaces;
(2) bilge piping and ballast piping;
(3) arrangement of air pipes, sounding pipes and overflow pipes;
(4) fuel oil feeding system for main and auxiliary engines and boilers;
(5) fuel oil transfer system;
(6) lubricating oil piping for main and auxiliary engines;
(7) cooling water piping system for main and auxiliary engines;
(8) compressed air piping system;
(9) steam piping;
(10) condensate and exhaust steam piping;
(11) boiler feed and blow-off piping;
(12) oil fuel heating piping;
(13) purgative system for fuel oil and lubricating oil;
(14) exhaust gas piping for main and auxiliary engines;
(15) arrangement of ventilation pipes for engine room;
(16) hydraulic systems;
(17) arrangement of drain pipes;
(18) additional plans and documents as may be deemed necessary by ISC.

2.1.2.2 For oil tankers, the following plans and documents are to additionally be submitted for approval:

(1) cargo oil piping system;
(2) bilge piping system of cargo pump rooms and cofferdams;
(3) cargo oil heating piping;
(4) arrangement of venting systems (including purge, gas-free systems);
(5) closed ullage system (where applied);
(6) arrangement of cargo pump tank.

2.1.2.3 For all ships, the following plans and documents are to be submitted for information (if relevant information is reflected in the submitted plans, submission of following plans and documents is not necessary):

(1) specifications of machinery installations;
(2) particulars of machinery equipment;
(3) calculations of machinery equipment.

2.1.2.4 The materials, sizes, types, design pressures and design temperatures of pipes, valves and fittings, and the set pressure of safety valves are to be clearly marked on plans. Where separate calculations are not submitted, necessary rule calculations are to be affixed to the plans.

2.1.3 Design pressure

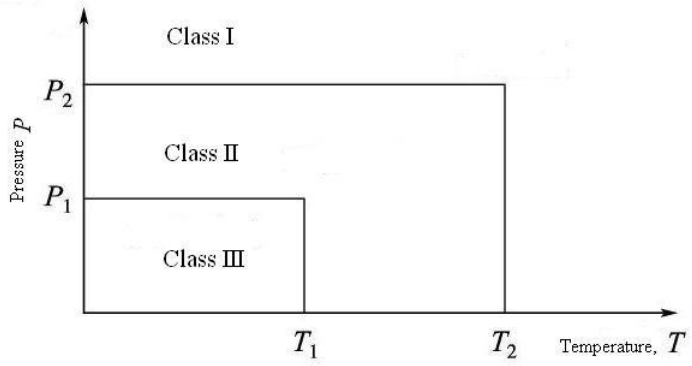
2.1.3.1 The design pressure for piping is the maximum permissible working pressure and it is not to be less than the highest set pressure of any safety valve or relief valve.

2.1.3.2 For pipes containing fuel oil, the design pressure is to be taken as given in Table 2.1.3.2.

Design pressure for pipes containing fuel oil **Table 2.1.3.2**

Working temperature / Working pressure	T ≤ 60℃	T > 60℃
P ≤ 0.7 MPa	0.3 MPa or highest working pressure, whichever is greater	0.3 MPa or highest working pressure, whichever is greater
P > 0.7 MPa	Highest working pressure	1.4 MPa or highest working pressure, whichever is greater

2.1.3.3 For special cases, the design pressure is to be specially considered.



2.1.4 Design temperature

2.1.4.1 The design temperature is to be taken as the maximum temperature of the internal fluid.
In the case of pipes for superheated steam, the temperature is to be taken as the designed operating steam temperature for the pipeline, provided that the temperature at the superheater outlet is closely controlled. Where temperature fluctuations exceeding 15℃ above the designed temperature are expected in normal service, the steam temperature to be used for determining the allowable stress is to be increased by the amount of this excess. For special cases, the design temperature is to be specially considered.

2.1.5 Classes of pipes

2.1.5.1 For the purpose of assigning appropriate testing requirements, types of joints to be adopted, heat treatment and weld procedure, pressure piping systems are divided into three classes in accordance with their design pressure and design temperature, as indicated in Table 2.1.5.1.

Piping system class **Table 2.1.5.1**

Piping system	Class I		Class II		Class III	
	Design pressure > P_2 (MPa)	Design temperature > T_2 (℃)	Design pressure ≤ P_2 (MPa)	Design temperature ≤ T_2 (℃)	Design pressure ≤ P_1 (MPa)	Design temperature ≤ T_1 (℃)
Steam	> 1.6	or > 300	≤ 1.6	and ≤ 300	≤ 0.7	and ≤ 170
Thermal oil	> 1.6	or > 300	≤ 1.6	and ≤ 300	≤ 0.7	and ≤ 150
Fuel oil, lub-oil, flammable hydraulic oil	> 1.6	or > 150	≤ 1.6	and ≤ 150	≤ 0.7	and ≤ 60
Other media	> 4.0	or > 300	≤ 4.0	and ≤ 300	≤ 1.6	and ≤ 200

Notes:

① For Class I piping, one parameter for design pressure and design temperature of Class I specified in the Table is to be met; For Class II piping, one parameter for design pressure and design temperature of Class II specified in the Table is to be met; For Class III piping, two parameters are not to exceed the provisions of Class III the Table.

② Toxic or corrosive media, flammable media heated above flash point or with flash point below 60℃ media and liquefied gas belong to class I. If means of special safeguards for preventing leakage and its consequences are provided (e.g. pipes led in positions where leakage of internal fluids will not cause a potential hazard or damage to surrounding areas which may include the use of pipe ducts, shielding, screening etc.), they may also belong to class II, but except toxic media.

③ Cargo pipes belong to class III.

④ Class III pipes may be used for open ended piping, e.g. drains, overflows, vents boiler waste steam pipes, etc.

⑤ Other media mean air, gases, water, and non-flammable hydraulic oil.

⑥ Thermal oil means the circulating oil used in the thermal oil system as specified in Section 8, Chapter 4 of this PART.

2.1.6 Materials

2.1.6.1 Materials to be used for pipes, valves and fittings are to be suitable for the medium and service for which the piping is intended. In the case of especially corrosive media, the material for the piping system is to be taken into consideration in each particular case.

2.1.6.2 Material for pipes, valves and relative fittings belonging to Classes I and II and for valves and pipes fitted on the ship's side and for valves fitted on the collision bulkhead are to be tested in accordance with the relevant requirements of ISC Rules for Materials and Welding.

2.1.6.3 Materials for pipes, valves and fittings of Class III are to be tested in accordance with applicable standards.

Section 2 CARBON, LOW ALLOY STEELS AND stainless steels

2.2.1 Carbon and low alloy steel pipes, valves and fittings

2.2.1.1 Classes I and II pipes are to be seamless steel pipes or welded pipes fabricated with a welding procedure approved by ISC.

2.2.1.2 In general, carbon and carbon-manganese steel pipes, valves and fittings are not to be used for medium temperatures above 400℃. Nevertheless, they may be used for higher temperatures if their metallurgical behavior and time dependent strength (UTS after 100,000 h) are in compliance with national or international codes or standards and if such values are guaranteed by the steel manufacturer.

Special alloy steel pipes, valve and fittings are to be employed according to the relevant requirements of ISC Rules for Materials and Welding.

2.2.2 Calculation of wall thickness

2.2.2.1 The minimum wall thickness $\delta$of steel pipes subject to internal pressure is not to be less than that determined by the following formula①:

$$\delta = \delta_0 + b + c \quad \text{mm}$$

where: δ_0 — the basic wall thickness, in mm, see 2.2.2.2 of this Section;

b — allowance for bending, in mm. The value for this allowance is to be chosen in such a way that the calculated stress in the bend, due to the internal pressure only, does not exceed the permissible stress. When this allowance is not determined by a more accurate procedure, it is to be taken according to 2.2.2.3 of this Section;

c — corrosion allowance, in mm, to be obtained from Table 2.2.2.1.

Corrosion allowance *C* for steel pipes **Table 2.2.2.1**

Usage of piping	*C*	Usage of piping	*C*
Overheat steam piping	0.3	Lubricating oil piping	0.3
Saturated steam piping	0.8	Fuel oil piping	1.0
Steam heating piping in cargo tank	2.0	Cargo oil piping	2.0
Boiler open-type feed piping	1.5	Refrigerant piping of refrigerating installation	0.3
Boiler close-type feed piping	0.5	Fresh water piping	0.8
Boiler blow-off piping	1.5	Sea water piping	3.0
Compressed air piping	1.0	Salt water piping in refrigerated hold	2.0
Hydraulic oil piping	0.3		

For pipes passing through tanks, an additional corrosion allowance is to be taken, depending on the external medium, in order to account for the external corrosion. Where pipes and any integral pipe joints are efficiently protected against corrosion by means of coating, lining, etc., the corrosion allowance may be reduced by not more than 50%. In the case of use of special alloy steel with sufficient corrosion resistance, the corrosion allowance may be reduced, even to zero.

2.2.2.2 The basic wall thickness δ_0 for steel pipes is to be determined by the following formula:

$$\delta_0 = \frac{pD}{2[\sigma]e + p} \quad \text{mm}$$

where: p — design pressure, in MPa, see 2.1.3 of this Chapter;

D — outside diameter of steel pipes, in mm;

① The formula applies to pipes where the ratio outside-diameter to inside-diameter does not exceed the value 1.7.

[σ] — permissible stress of steel pipes, in N/mm^2, see 2.2.2.4 of this Section;

e — welding efficiency factor. For seamless steel pipes and electric resistance or induction welded steel pipes, e is to be taken as 1; for pipes made by other methods, e will be specially considered.

2.2.2.3 Bending allowance b is not to be less than that determined by the following formula:

$$b = 0.4 \frac{D}{R} \delta_0 \quad \text{mm}$$

where: R — radius of curvature of a pipe bend at the centre line of the pipe, in mm, in general, R is not to be less than 3D;

D — outside diameter of steel pipes, in mm;

δ_0 — basic wall thickness, in mm, see 2.2.2.2 of this Section.

2.2.2.4 Permissible stress [σ] of steel pipes is to be taken as the lowest of the following values:

$$[\sigma] = \frac{R_m}{2.7} \quad \text{N/mm}^2$$

$$[\sigma] = \frac{R_{eH}^T}{1.6} \quad \text{N/mm}^2$$

$$[\sigma] = \frac{\sigma_D^T}{1.6} \quad \text{N/mm}^2$$

$$[\sigma] = \sigma_c^T \quad \text{N/mm}^2$$

where: R_m — tensile strength of material at room temperature, in N/mm^2;

R_{eH}^T — yield stress or 0.2% proof stress ($R_{p0.2}$) of material at design temperature, in N/mm^2;

σ_D^T — average stress of material to produce rupture in 100,000 h at design temperature, in N/mm^2;

σ_c^T — average stress to produce 1% creep in 100,000 h at the design temperature, in N/mm^2;

R_m, R_{eH}^T, σ_D^T are to comply with the relevant requirements of ISC Rules for Materials and Welding. National or international standards may be accepted for R_{eH}^T. σ_c^T may be used as appropriate based on reliable conditions if it is deemed necessary.

2.2.2.5 The minimum wall thickness δ mentioned in 2.2.2.1 above has not taken into account the negative manufacturing tolerance, where there is any negative tolerance allowable in manufacture, the nominal thickness δ_m of pipes is not to be less than that determined by the following formula:

$$\delta_m = \frac{\delta}{1 - \frac{a}{100}} \quad \text{mm}$$

where: a — percentage of negative manufacturing tolerance on thickness.

2.2.2.6 Where the minimum thickness calculated by the formula specified in 2.2.2.5 is less than that shown in Table 2.2.2.6(1), Table 2.2.2.6(2) or Table 2.2.2.6(3), the minimum nominal thickness for the appropriate standard pipe size shown in the Tables is to be used.

For threaded pipes, the thickness is to be measured at the bottom of the thread.

External diameter and minimum nominal thickness for steel pipes, in mm Table 2.2.2.6(1)

External diameter, *D*	Minimum nominal thickness (δ)			
	General pipe③④⑥⑧⑨⑩	Air pipe, overflow pipe and sounding pipe of tank related to hull structure①②③④⑥⑦⑧	Bilge and ballast pipe, general sea water pipe and steam heating coil in liquid tank①③④⑤⑥⑦⑧	Bilge pipe, air pipe, overflow pipe and sounding pipe through ballast tank and fuel oil tank. Ballast pipe through fuel oil tank and fuel oil pipe through ballast tank①②③④⑤⑥⑦⑧

13.5~19.3	1.8			
20	2.0			
21.3~25	2.0		3.2	
26.9~33.7	2.0		3.2	
38~44.5	2.0	4.5	3.6	6.3
48.3	2.3	4.5	3.6	6.3
51~63.5	2.3	4.5	4.0	6.3
70	2.6	4.5	4.0	6.3
76.1~82.5	2.6	4.5	4.5	6.3
88.9~108	2.9	4.5	4.5	7.1
114.3~127	3.2	4.5	4.5	8.0
133~139.7	3.6	4.5	4.5	8.0
152.4~168.3	4.0	4.5	4.5	8.8
177.8	4.5	5.0	5.0	8.8
193.7	4.5	5.4	5.4	8.8
219.1	4.5	5.9	5.9	8.8
244.5~273	5.0	6.3	6.3	8.8
298.5~368	5.6	6.3	6.3	8.8
406.4~457	6.3	6.3	6.3	8.8

Notes:

① Where pipes and any integral pipe joints are efficiently protected against corrosion by means of coating, lining, etc., the minimum wall thickness may be reduced by an amount up to 1 mm.

② For sounding pipes, except those for cargo tanks with cargo having a flash point less than 60℃, the minimum wall thickness is intended to apply to the part outside the tank.

③ For threaded pipes, where allowed, the minimum wall thickness is to be measured at the bottom of the thread.

④ The external diameters and thicknesses have been selected from ISO Recommendations R336 for welded and seamless steel pipes. For pipes covered by other Standards, slightly reduced thicknesses may be accepted.

⑤ The minimum wall thickness for bilge lines and ballast lines through deep tanks will be subject to special consideration. The minimum wall thickness for ballast lines through cargo tanks is not to be less than that specified in Table 5.3.4.2 of Section 3, Chapter 5 of this PART.

⑥ The minimum wall thickness for pipes larger than 457 mm nominal size is to be in accordance with a national or international standard and in any case not less than the minimum wall thickness of the appropriate column indicated for 406.4 to 457 mm pipe size in Table 2.2.2.6(1).

⑦ The minimum internal diameters of bilge, sounding, air and overflow pipes are to be:

Bilge 50 mm
Sounding 32 mm
Air and overflow 50 mm

⑧ In general, the minimum thickness listed in this Table is the nominal wall thickness and no allowance need be made for negative tolerance and reduction in thickness due to bending.

⑨ The minimum wall thickness of exhaust gas pipe will be subject to special consideration.

⑩ The minimum wall thickness for cargo oil lines will be subject to special consideration.

External diameter and minimum nominal thickness δ for stainless steel pipes, in mm **Table2.2.2.6(2)**

External diameter (D)	Minimum nominal thickness (δ)
≤10	1.0
11~18	1.5
19~83	2.0
84~169	2.5
170~246	3.0
247~340	3.5
341~426	4.0
427~511	4.5
512~597	5.0

External Diameter and Minimum Nominal Wall Thickness for Austenitic Stainless Steel Pipes, in mm **Table 2.2.2.6(3)**

External diameter (D)	Minimum nominal wall thickness (δ)
10.2 ~ 17.2	1.0
21.3 ~ 48.3	1.6
60.3 ~ 88.9	2.0
114.3 ~ 168.3	2.3
219.1	2.6
273.0	2.9
323.9 ~ 406.4	3.6
> 406.4	4.0

Note: Diameters and thicknesses according to national or international standards may be accepted.

2.2.2.7 The minimum wall thickness of the scuppers and discharge pipes is to comply with the relevant requirements of regulation 22, Annex I to Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

2.2.2.8 The minimum wall thickness of air pipes above the weather deck is to comply with the relevant requirements of 1.12.7.5 of PART TWO of the Rules.

Section 3 COPPER AND COPPER ALLOYS

2.3.1 Copper and copper alloy pipes, valves and fittings

2.3.1.1 Copper and copper alloy pipes used in Classes I and II piping systems are to be seamless.

2.3.1.2 Materials of copper and copper alloys for Class III piping systems are to be manufactured and tested in accordance with the approved standards.

2.3.1.3 In general, copper and copper alloy pipes, valves and fittings are not be used for media having a temperature above the following limits:

copper and aluminum brass: 200℃;

copper nickel: 300℃;

special bronze suitable for high temperature services: 260℃.

2.3.2 Calculation of wall thickness

2.3.2.1 The minimum wall thickness δ of copper and copper alloy pipes subject to internal pressure is not to be less than that determined by the following formula①:

$$\delta = \delta_0 + b + c \quad \text{mm}$$

where: δ_0 — the basic wall thickness, in mm, see 2.3.2.2 of this Section;

b — allowance for bending, in mm. The value for this allowance is to be chosen in such a way that the calculated stress in the bend, due to the internal pressure only, does not exceed the permissible stress. When this allowance is not determined by a more accurate procedure, it is to be taken according to 2.3.2.3 of this Section;

c — corrosion allowance, in mm; for copper, brass and similar alloys, copper-tin alloys except those with lead contents, and copper-nickel alloys where the nickel content is less than 10%, c = 0.8 mm; copper-nickel alloys where the nickel content is 10% or greater, c = 0.5

① The formula applies to pipes where the ratio outside-diameter to inside-diameter does not exceed the value 1.7.

mm; where the media are non-corrosive relative to the pipe material, $c = 0$.

2.3.2.2 The basic wall thickness of copper and copper alloy pipes is to be determined by the following formula:

$$\delta_0 = \frac{pD}{2[\sigma]e + p} \quad \text{mm}$$

where: p — design pressure, in MPa, see 2.1.3 of this Chapter;
D — outside diameter of pipe, in mm;
$[\sigma]$ — permissible stress, in N/mm^2, obtained from Table 2.3.2.2;
e — efficiency factor, $e = 1$ for seamless copper pipes and for welded copper pipes delivered by manufacturers approved for making welded copper pipes which are considered an equivalent to seamless copper pipes. For copper pipes made by other methods, e will be specially considered.

Allowable stress of copper and copper alloy pipes [σ] **Table 2.3.2.2**

Materials	Material condition	Tensile strength (N/mm^2)	Allowable stress (N/mm^2)										
			Design temperature (℃)										
			50	75	100	125	150	175	200	225	250	275	300
copper	annealing	215	41	41	40	40	34	27.5	18.5	—	—	—	—
Aluminum brass	annealing	325	78	78	78	78	78	51	24.5	—	—	—	—
copper-nickel alloys CuNi5Fe1Mn CuNi10Fe1Mn	annealing	275	68	68	67	65.5	64	62	59	56	52	48	44
copper-nickel alloys CuNi30	annealing	365	81	79	77	75	73	71	69	67	65.5	64	62

Notes:
① If the metal temperature is between the values listed in the Table, allowable stress may be determined by linear interpolation.
② The allowable stresses of materials not covered by the Table are to submit detailed information.

2.3.2.3 Bending allowance b is not to be less than that determined by the following formula:

$$b = 0.4\frac{D}{R}\delta_0 \quad \text{mm}$$

where: R — radius of curvature of a pipe bend at the centre line of the pipe, in mm. In general, R is not to be less than $3D$;
D — outside diameter of pipe, in mm;
δ_0 — basic wall thickness, in mm, see 2.3.2.2 of this Section.

2.3.2.4 The minimum wall thickness δ mentioned in 2.3.2.1 above has not taken into account the negative manufacturing tolerance, where there is any negative tolerance allowable in manufacture, the nominal thickness of pipes is not to be less than that determined by the following formula:

$$\delta_m = \frac{\delta}{1 - \frac{a}{100}} \quad \text{mm}$$

where: a — percentage of negative manufacturing tolerance on thickness.

2.3.2.5 Where the minimum wall thickness calculated by the formula specified in 2.3.2.4 is less than that shown in Table 2.3.2.5, the minimum nominal thickness for the appropriate standard pipe size shown in the Table is to be used.
For threaded pipes, the thickness is to be measured at the bottom of the thread.

External diameter and minimum nominal thickness δ_m for copper and copper alloy pipes, in mm **Table 2.3.2.5**

Outside diameter (D)	Minimum nominal thickness (δ_m)	
	Copper	Copper alloys
8~10	1.0	0.8
12~20	1.2	1.0
25~44.5	1.5	1.2
50~76.1	2.0	1.5
88.9～108	2.5	2.0
133～159	3.0	2.5

Outside diameter (D)	Minimum nominal thickness (δ_m)	
	Copper	Copper alloys
193.7～267	3.5	3.0
273～470	4.0	3.5
508	4.5	4.0

Notes:
① The outside diameters and the thickness have been selected from ISO Standards.
② For pipes covered by other standards, slightly reduced thickness may be accepted.

Section 4 OTHER MATERIALS

2.4.1 Grey cast iron pipes, valves and fittings

2.4.1.1 Grey cast iron pipes, valves and fittings are not to be used in Class I and Class II piping systems. Grey cast iron valves and fittings may be used in Class II steam piping but the design temperature does not exceed 220℃.

2.4.1.2 Grey cast iron pipes, valves and fittings may, in general, be accepted in Class III piping systems, in cargo lines within cargo tanks of tankers , but grey cast iron is not to be used for the following:

(1) cargo oil pipelines having pressures exceeding 1.6 MPa on weather decks of oil tankers;
(2) pipes, valves and fittings intended for conveying media having temperatures above 220℃;
(3) piping may be subjected to pressure shock, excessive strains and vibration;
(4) ship-side valves and fittings and sea valves, pipes fitted on the ship sides and sea chest;
(5) valves fitted on the collision bulkhead;
(6) valves under static head fitted on the outside of fuel tank walls;
(7) boiler blow-off systems;
(8) pipes for steam, fire extinguishing, bilge and ballast systems.

Grey cast iron may be accepted for pressures up to 1.6 MPa for cargo oil pipe lines on weather decks of oil tankers except for manifolds and their valves and fittings connected to cargo handling hoses.

2.4.2 Nodular graphite cast iron pipes, valves and fittings

2.4.2.1 Ferritic nodular graphite iron castings for pipes, valves and fittings in Class II and Class III piping systems are to be made in a grade having a specified minimum elongation not less than 12% on a gauge length of $5.65\sqrt{S_0}$, where S_0 is the cross-sectional area of the test piece.

2.4.2.2 Ferritic nodular graphite iron pipes, valves and fittings may be accepted for bilge, ballast and cargo oil piping.

2.4.2.3 Ferritic nodular graphite cast iron pipes, valves and fittings are not to be used in piping systems for conveying media having temperatures exceeding 350℃.

2.4.2.4 Where ferritic nodular graphite iron castings are used for ship-side pipes, valves and fittings, the properties of this material are to comply with the relevant requirements of ISC Rules for Materials and Welding.

2.4.2.5 Where the elongation is less than the minimum required in 2.4.2.1 of this Section, the material is to be subject to the same limitations as grey cast iron.

2.4.3 Plastic pipes

2.4.3.1 The ranges and locations of plastic pipes used in ships are to comply with the provisions in Table 1 of Appendix I, and the plastic pipes are to comply with the fire endurance requirements in the Table.

2.4.3.2 Plastic pipes used on ships are to be selected in relation to their chemical composition, physical and mechanical properties, and temperature limits.

2.4.3.3 Plastic pipes are in general not to be used for media with a temperature above 60℃ or below 0℃.

2.4.3.4 Plastic pipes used on ships are to be designed, manufactured, used and test in accordance with the relevant requirements in Appendix 1 of this Chapter.

2.4.4 Flexible hoses

2.4.4.1 Flexible hoses mean short length of metallic or non-metallic hoses normally with prefabricated end fittings ready for installation.

2.4.4.2 Flexible hoses may be used for a permanent connection between a fixed piping system and items of machinery, as well as temporary connection between portable equipment and pipes.

2.4.4.3 Flexible hoses are to be designed, manufactured, used and tested in accordance with the relevant

requirements of Appendix 2 of this Chapter.

Section 5 CONNECTION OF PIPE LENGTHS, HEAT TREATMENT AND NON-DESTRUCTIVE TESTING

2.5.1 Connection of pipe lengths

2.5.1.1 Direct connection of pipe lengths may be obtained by:

(1) welded butt-joints between pipes or between pipes and valve chests or other fittings, the welded butt-joints are to be of full penetration type with or without special provisions for the quality of root side①;
(2) slip-on sleeve welded joints, the slip-on sleeve welded joints are to have sleeves and relative welding of adequate dimensions conforming to the recognized standard;
(3) threaded sleeve joints of approved type;
(4) mechanical joints.

2.5.1.2 The application of the aforesaid types of connection is as follows:

(1) Welded butt-joints and slip-on sleeve welded joints are to comply with the requirements specified in Table 2.5.1.2(1).

Connection of pipe length **Table 2.5.1.2(1)**

Type of connection	Allowed for classes	Allowed for outside diameter
Butt welded joints with special provision for a high quality of root side	I, II, III	No restriction
Butt welded joints without special provision for a high quality of root side	II, III	
Slip-on sleeve welded joints	III	
	I, II, except for piping systems conveying toxic media where fatigue, severe erosion is expected to occur	$D \leq 88.9$ mm

(2) Slip-on threaded joints are to comply with requirements of a recognized standard. Slip-on threaded joints may be used for outside diameters as stated below except for piping systems conveying toxic or flammable media or services where fatigue, severe erosion or crevice is expected to occur. Threaded joints in CO_2 systems are to be allowed only inside protected spaces and in CO_2 cylinder rooms.

① Threaded joints for direct connectors of pipe lengths with tapered thread may be allowed for Class I, outside diameter not more than 33.7 mm as well as Class II and Class III, outside diameter not more than 60.3 mm.

② Threaded joints for parallel thread may be allowed for Class III, outside diameter not more than 60.3 mm.

③ In particular cases, sizes in excess of those mentioned above may be accepted if they satisfy the requirements of recognized international or national standards.

2.5.2 Flange connections

2.5.2.1 Typical flange connections are indicated in Figure 2.5.2.1.

Slip-on joints, sleeve threaded joints and other types of direct connection of pipe lengths (e.g. bell and spigot joints) may be allowed in each particular case for small diameter and depending upon the service conditions.

2.5.2.2 The above-mentioned types of flange connections are to be selected in accordance with the requirements specified in Table 2.5.2.2.

Application of typical flange connections **Table 2.5.2.2**

Piping class	Toxic or corrosive media④, flammable media④, liquefied gas	Lubricating oil and fuel oil	Steam③ and hot oil	Other media①②③
I	A,B⑥	A,B	A,B⑥	A,B
II	A,B,C	A,B,C,E⑦	A,B,C,D⑤,E⑤	

① The expression "special provisions for the quality of root side" means that butt welds were accomplished as double welded or by use of a backing ring or inert gas back-up on first pass, or other similar methods accepted by ISC.

III		A,B,C,E	A,B,C,D,E	A,B,C,D,E,F②

Notes:
① Including water, air, other gases, hydraulic oil.
② Type F for water pipes and open ended lines only.
③ Only type A when design temperature exceeds 400℃.
④ Only type A when design pressure exceeds 1 MPa.
⑤ Types D and E are not be used when design temperature exceeds 250℃.
⑥ Type B for outside diameter < 150 mm only.
⑦ Type E for oil piping when design temperature < 150℃ and design pressure < 1.6 MPa only.

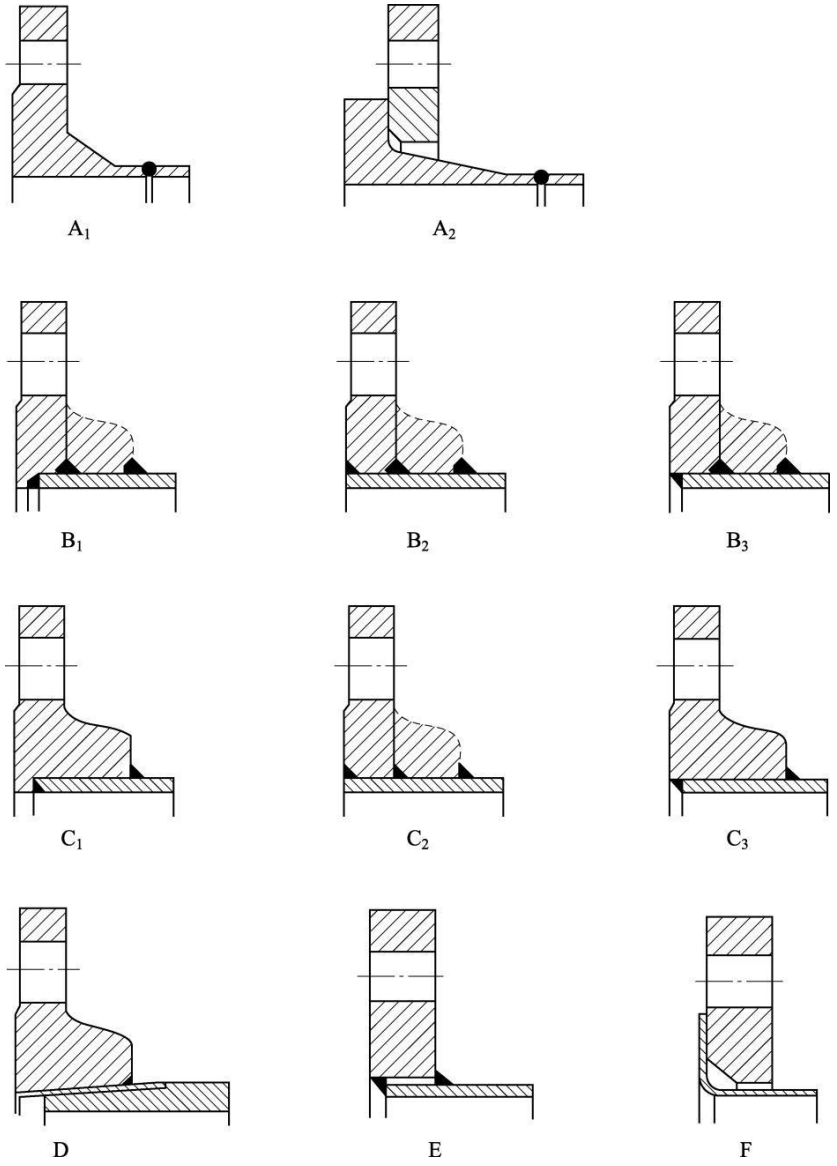

Figure 2.5.2.1 Typical flange connections

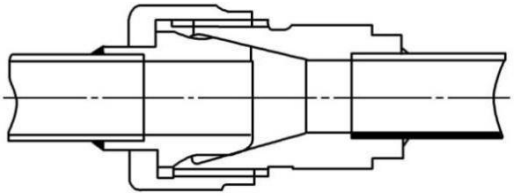
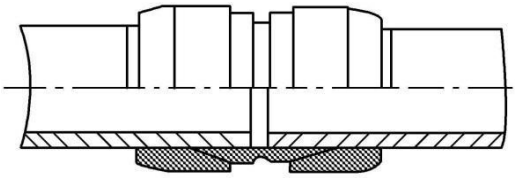
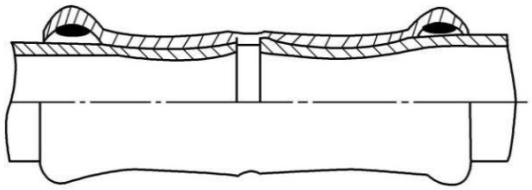
Notes: ① For type D, the pipe and flange are to be screwed with a tapered thread and the diameter of the screw portion of the pipe over the thread is not to be appreciably less than the outside diameter of the unthreaded pipe. After the flange has been screwed hard home, the pipe is to be expanded into the flange.
② The leg length of the fillet weld and the penetration of the flange edge, as shown in the Figure, are in general to be 1.5 times the wall thickness of the pipe, but not less than 5 mm.

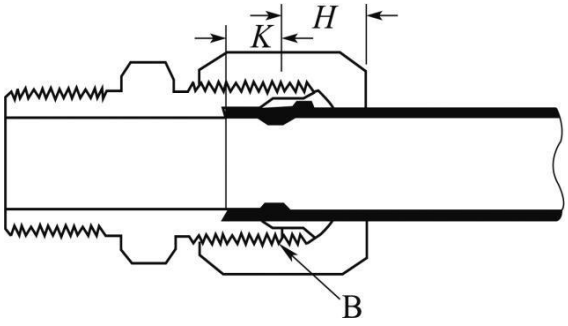
2.5.2.3 The dimensions of flanges and relative bolts are to be chosen in accordance with the national standards or acceptable standards. For special application, the dimensions of flanges and relative bolts are to be subject to special consideration①.

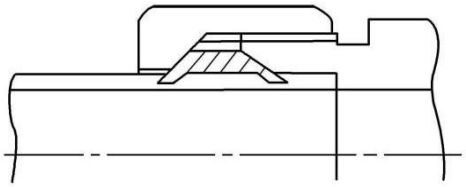
① For special applications where the fitting temperature, pressure and size of the flange exceed reliable limits, a complete

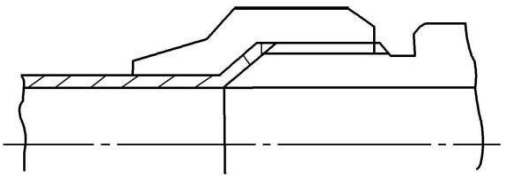






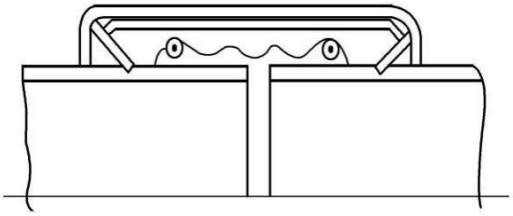


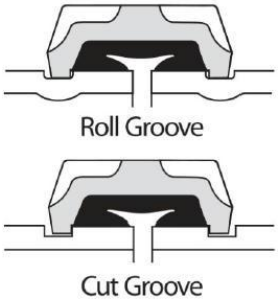


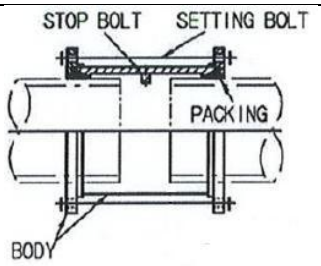


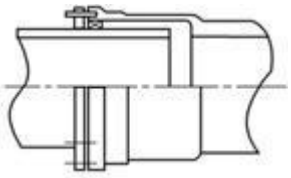
Gaskets are to be suitable for the media being conveyed under design pressure and temperature conditions and their dimensions and configuration are to be in accordance with national or acceptable standards.
Flange connections are to be in accordance with national or international standards that are applicable to the piping system and are to recognize the boundary fluids, design pressure and temperature conditions, external or cyclic loading and location.

2.5.3 Mechanical joints









2.5.3.1 The different mechanical joints applicable to this paragraph are indicated in Table 2.5.3.1(1). The mechanical joints are to be subject to type approval based on different usage and location in accordance with the requirements of Appendix 3 of this Chapter.
2.5.3.2 Where appropriate, mechanical joints are to be of fire resistant type as required by Table 2.5.3.1(2). Fire endurance test is specified in 1.5.5(6), Appendix 3 of this Chapter.
2.5.3.3 Material of mechanical joints is to be compatible with the piping material and internal and external media.
2.5.3.4 Application of mechanical joints and their acceptable use for each service is indicated in Table 2.5.3.1(2); dependence upon the Class of piping and pipe dimensions is indicated in Table 2.5.3.1(3).
In particular cases, sizes in excess of those mentioned above may be accepted if in compliance with a recognized national and/or international standard.
2.5.3.5 Where the application of mechanical joints results in reduction in pipe wall thickness due to the use of bite type rings or other structural elements, this is to be taken into account in determining the minimum wall thickness of the pipe to withstand the design pressure.
2.5.3.6 Mechanical joints, which in the event of damage could cause flooding or fire, are not to be used in piping sections directly connected to the ship's side below the bulkhead deck of passenger ships (or freeboard deck of cargo ships) or tanks containing flammable fluids. The number of mechanical joints in flammable fluid systems is to be kept to a minimum. In general, flanged joints conforming to recognized standards are to be used.
2.5.3.7 Mechanical joints in bilge systems of machinery space and higher fire risk space (e.g. cargo pump room and vehicle space) are to be of fire resistant type. For the required fire resistant mechanical joints, see Table 2.5.3.1(2).
2.5.3.8 Mechanical joints are to be tested where applicable, to a burst pressure of 4 times the design pressure. When the design pressure exceeds 20 MPa, the burst pressure will be specially considered.
2.5.3.9 Piping in which a mechanical joint is fitted is to be adequately adjusted, aligned and supported. Supports or hangers are not to be used to force alignment of piping at the point of connection.
2.5.3.10 Slip-on joints are not to be used in pipelines in cargo holds, tanks and other spaces which are not easily accessible (refer to MSC/Circ.734), except that these joints may be permitted in tanks that contain the same media.
Usage of slip type slip-on joints as the main means of pipe connection is not permitted except for cases where compensation of axial pipe deformation is necessary.
2.5.3.11 Mechanical joints are not to be used in the following cases:
(1) bilge piping through ballast tanks and fuel tanks;
(2) sea water and ballast piping (including air and overflow pipes) through cargo holds and fuel tanks;
(3) fuel and oil piping (including air and overflow pipes) through machinery spaces, cargo holds and ballast tanks.
2.5.3.12 The installation of mechanical joints is to be in accordance with the manufacturer's assembly instructions. Where special tools and gauges are required for installation of the joints, these are to be supplied by the manufacturer.

calculation is to be carried out for bolts and flanges.

∗ Fire endurance test as specified in 1.5.5(6) of Appendix 3 of this Chapter.
Fire resistance capability:
If mechanical joints include any components which readily deteriorate in case of fire, the following footnotes are to be observed:
① Fire endurance test shall be applied when mechanical joints are installed in pump rooms and open decks.
② Slip on joints are not accepted inside machinery spaces of category A or accommodation spaces. May be accepted in other machinery spaces provided the joints are located in easily visible and accessible positions.
③ Approved fire resistant types except in cases where such mechanical joints are installed on open decks, as defined in SOLAS Reg. II-2/9.2.3.3.2.2(10) and not used for fuel oil lines.
④ Fire endurance test shall be applied when mechanical joints are installed inside machinery spaces of category A.
General:
⑤ Only above bulkhead deck of passenger ships and freeboard deck of cargo ships.
⑥ Slip type slip-on joints as shown in Table 2.5.3.1(1) may be used for pipes on deck with a design pressure of 10 bar or less.
⑦ If a connection has passed the "30 min dry" test, it is considered suitable also for applications for which the "8 min dry+22 min wet" and/or "30 min wet " tests are required. If a connection has passed the "8 min dry+22 min wet" test, it is considered suitable also for applications for which the "30 min wet" test is required.

2.5.4 Heat treatment and non-destructive testing

2.5.4.1 The heat treatment and non-destructive testing of piping systems are to comply with the relevant requirements of ISC Rules for Materials and Welding.

Section 6 PUMPS, VALVES AND FITTINGS

2.6.1 Pumps

2.6.1.1 Pumps are to be designed and manufactured according to accepted standards.

2.6.1.2 Hydraulic tests

All components of pumps subject to pressure are to be subject to hydraulic tests in workshop prior to assembly. The hydraulic test pressure is to be 1.5 times the design pressure, but need not exceed the design pressure plus 7 MPa.

For centrifugal pumps, the design pressure is to be taken as the maximum pressure head on the performance curve. For displacement pumps, the design pressure is to be taken as the relief valve setting pressure.

For steam driven pumps, the test pressure at the steam side is to be 1.5 times the steam working pressure.

---

① This requirement is applicable to any mechanical pipe joints submitted for approval from 1 January 2020 and to any renewal of type approval of existing design of mechanical pipe joint after 1 January 2020.

2.6.1.3 Capacity tests

Pump capacities are to be checked with the pump operating at design conditions (rated speed and pressure head). For centrifugal pumps, the pump characteristic (head-capacity) design curve is to be verified to the satisfaction of the Surveyor.

Capacity tests may be waived if previous satisfactory tests have been carried out on similar pumps.

2.6.1.4 Relief valve capacity test

For positive displacement pumps with an integrated relief valve, the valve's setting and full flow capacity corresponding to the pump maximum rating is to be verified.

The operational test for relief valve capacity may be waived if previous satisfactory tests have been carried out on similar pumps.

2.6.2 Valves and fittings

2.6.2.1 Valves are to be designed and manufactured according to accepted standards. For other structurally new-type valves or non-standard valves, detailed drawings and information are to be submitted.

2.6.2.2 The strength of valves and fittings in piping system is to be appropriate to the strength required by the connected pipes and is to be able to work efficiently under the maximum working pressure. Valves are to be made of steel, cast iron, copper, copper alloy or other materials suitable for the intended service.

2.6.2.3 All valves are to be so constructed as to prevent the possibility of valve bonnets or glands being slackened back or loosened when the valves are operated. Screwed-on valve bonnets are not to be used for valves with nominal diameter exceeding 40 mm in Class I and Class II piping systems, sea valves, ship-side valves and valves in flammable liquid system.

2.6.2.4 Valves on board ships are to be of such construction that the closing of which is obtained by clockwise rotation of the hand wheel, and the opening by counter-clockwise rotation.

2.6.2.5 Indicators are to be provided to show the open and closing condition of the valves, unless this can be observed in some other way; for remotely controlled valves, the remote control position is also to show the open and closing condition of the valve.

2.6.2.6 Valves and cocks are to be fitted with nameplates to indicate their purposes. The casing of non-return valves is to be permanently marked with flow direction.

2.6.2.7 The welded necks on the valve bodies are to be long enough to ensure that the valves will not deform due to welding and subsequent heat treatment of the joints.

2.6.2.8 All valves are to be subject to hydraulic tests in workshop. The hydraulic test pressure is to be 1.5 times the design pressure.

2.6.3 Air pipe closing devices

2.6.3.1 Where air pipes are required by 1.12.7.5 of PART TWO of the Rules to be fitted with automatic closing devices, they are to be designed, manufactured and tested in accordance with the requirements of Appendix 4 of this Chapter.

Section 7 TESTS

2.7.1 Hydraulic tests for piping prior to installation on board

2.7.1.1 All Classes I and II pipes and their associated fittings and, all steam pipes, feed pipes, compressed air pipes and fuel oil pipes having a design pressure greater than 0.35 MPa together with their fittings are to be hydraulically tested after completion of manufacture and before insulating and coating.

2.7.1.2 The hydraulic test pressure P_s is not to be less than that determined by the following formula:

$$P_s = 1.5p \quad \text{MPa}$$

where: p — design pressure, in MPa, see 2.1.3 of this Chapter.

2.7.1.3 For steel pipes and integral fittings for use in systems where the design temperature exceeds 300℃, test pressure P_s is to be determined by the following formula, but need not exceed 2 p.

$$P_S = 1.5\frac{[\sigma]_{100}}{[\sigma]_t}p \quad \text{MPa}$$

where: p — as defined in 2.7.1.2;

$[\sigma]_{100}$ — permissible stress for 100℃, in N/mm^2;

$[\sigma]_t$ — permissible stress for the design temperature, in N/mm^2.

The test pressure may be reduced to 1.5 *p* where it is necessary to avoid excessive stress in way of bends

and T-connections. In no case is the membrane stress to exceed 90% of the yield stress at the testing temperature.
2.7.1.4 When the hydraulic test of piping is carried out on board, it may be carried out concurrently with the tightness tests required after assembly on board.
2.7.1.5 For pipes with an internal diameter less than 15 mm, the hydraulic test may be waived.
2.7.1.6 When, for technical reasons, it is not possible to carry out complete hydraulic test for all sections piping, prior to assembly on board, applications are to be submitted to ISC for approval for testing the closing lengths of piping, particularly in respect to closing seams.

2.7.2 Hydraulic tests for valves and fittings prior to installation on board

2.7.2.1 Valves and fittings non-integral with the piping system, intended for Classes I and II, are to be hydraulically tested in accordance with recognized standards, but the test pressure is not to be less than 1.5 times the design pressure.
Valves, cocks and distance pieces intended to be fitted on the ship side below the load waterline are to be tested by hydraulic pressure not less than 0.5 MPa.

2.7.3 Testing after assembly on board

2.7.3.1 All piping systems are to be checked for leakage under working conditions.
2.7.3.2 Fuel (oil or gas) piping, heating coils in tanks, bilge pipes in way of double bottom tanks or deep tanks and hydraulic piping are to be tested by hydraulic pressure in accordance with Table 2.7.3.2.

Hydraulic tests after assembly on board **Table 2.7.3.2**

Piping system	Test pressure
Fuel (oil or gas) piping	1.5 times design pressure, but not less than 0.4 MPa
Heating coils in tanks	
Bilge pipes in way of double bottom tanks or deep tanks	Not less than test pressure of the tank
Hydraulic piping	1.25 times design pressure, but no need to exceed design pressure plus 7 MPa

2.7.3.3 Where Classes I and II pipes are butt welded together during assembly on board, they are to be tested by hydraulic pressure in accordance with the requirements of 2.7.1.1 to 2.7.1.4 after welding. During installation and before the hydraulic test is carried out, the pipe lengths may be insulated, except in way of the joints.
2.7.3.4 The hydraulic test required in 2.7.3.3 of this Section may be omitted provided non-destructive tests by ultrasonic or radiographic methods are carried out on the entire circumference of all butt welds with satisfactory results.

Section 8 ARRANGEMENT

2.8.1 Piping arrangement

2.8.1.1 All pipes are to be properly secured, and provision is to be made to avoid excessive stresses caused by thermal expansion in pipes or due to deflection of ship structure.
2.8.1.2 Penetration pieces or steel pads are to be provided for pipes passing through watertight or gastight structures. If pipes are fixed on watertight bulkhead by bolts, bolt holes are not to pass through bulkhead. For pipes pass through deck or bulkhead with fire division, their arrangement is not to damage fire division of deck or bulkhead.
2.8.1.3 The pipe piercing the collision bulkhead below the freeboard deck (bulkhead deck for passenger ships) is to be fitted with a remotely controlled valve capable of being operated from above the freeboard deck (bulkhead deck for passenger ships). The valve is to be normally closed. If the remote control system should fail during operation of the valve, the valve is to close automatically or be capable of being closed manually from a position above the freeboard deck (bulkhead deck for passenger ships).
The above-mentioned valves are to be fitted on the forward or after side of the collision bulkhead provided that the space in which they are located is not a cargo space.
All valves are to be of steel, bronze or other approved ductile material. Valves of ordinary cast iron or similar material are not acceptable.
2.8.1.4 The collision bulkhead may be pierced below the bulkhead deck by not more than one pipe for dealing with fluid in the forepeak tank. If the forepeak is divided to hold two different kinds of liquids, the

collision bulkhead of each compartment may be allowed to be pierced below the bulkhead deck for passenger ships by one pipe.
2.8.1.5 For ships required for damage stability, the arrangement is to ensure that the continuing flooding will not extend to the compartments other than those with assumption of flooding , provided the piping system is fitted in the assumed flooding compartments.
2.8.1.6 Fresh water pipes are not to be led through oil tanks, nor oil pipes through fresh water tanks. Where it is impracticable to do so, the pipes are to be led inside an oil-tight pipe tunnel.

2.8.2 Separation of tanks
2.8.2.1 Where the following tanks are adjacent to each other, they are to be separated by cofferdams:
(1) lubricating oil tanks and fresh water tanks;
(2) boiler feed water tanks and fuel oil tanks;
(3) fresh water tanks and fuel oil tanks;
(4) boiler feed water tanks and lubricating oil tanks.
2.8.2.2 Where the fuel oil tank is directly adjacent to lubricating oil tank, the welding of the adjacent bulkhead is to be of full penetration type.

2.8.3 Corrosion protection
2.8.3.1 Steel pipes are to be protected against corrosion, and protective coatings are to be applied on completion of all fabrication, i.e. bending, forming and welding of the steel pipes.

2.8.4 Fire protection
2.8.4.1 Air, overflow and sounding pipes for fuel oil tanks are not to be led through living quarters. Where this is not practicable, no detachable pipe joint is permissible in these spaces.
2.8.4.2 All steam, oil and water pipes as well as oil and other liquid tanks are not to be placed above or behind the switchboard. If this is not practicable, suitable protective means are to be provided.
In addition, oil pipes and oil tanks are not to be directly placed above the boilers, uptakes, steam pipes, exhaust gas pipes and silencers. If this is impracticable, effective means are to be made to prevent oil dropping onto the hot surfaces of the above-mentioned pipes or equipment.

2.8.5 Protection
2.8.5.1 Seawater pipes in cargo holds for dry cargoes, including cargo spaces of container ships, ro-ro ships, are to be protected from impact of cargo where they are liable to be damaged.
2.8.5.2 All pipes, fittings, pumps, filters and other equipment of piping systems are to be provided with drain valves or cocks where necessary.
2.8.5.3 The pipes which may be subject to a pressure greater than the design value are to be fitted with relief valves at the delivery side of pumps. The discharge from relief valves fitted in oil pipelines is to be led to the suction side of pumps or tanks. Heaters and air compressor coolers are also to be fitted with relief valves. The releasing pressure of relief valves is, in general, not to be greater than the design pressure of pipelines.
2.8.5.4 Where pressure-reducing valves are fitted in the pressure piping, a relief valve and a pressure gauge are to be fitted behind the pressure-reducing valve and a by-pass pipe fitted with a screw-down valve is to be provided. Or, at least an additional spare pressure reducing valve for replacement at any time is to be provided. The provision of pressure-reducing valves in the gas supply piping of the control system and relevant requirements are given in 2.2.2.2, PART SEVEN of the Rules.

2.8.6 Insulation
2.8.6.1 The insulation lagged on the machinery surfaces with a temperature over 220℃ is to comply with the provisions in 1.3.6.3 of this PART. The insulation in way of dismountable joints and valves is to be easily renewed.
2.8.6.2 Pipes passing through refrigerated spaces (including fish rooms), excluding those intended to serve such spaces, are to be well insulated to prevent freezing and from the steel structure.
2.8.6.3 Where the pipes pass through chambers intended for temperatures of 0℃ or below, they are in general to be insulated from the steel structure of these chambers.

2.8.7 Compensation for expansion
2.8.7.1 Suitable provision for compensation is to be made for all pipes subject to expansion, contraction or other strain, such as bends, loops, or expansion joints as required.
2.8.7.2 The adjoining pipes are to be suitably aligned and anchored. Where necessary, expansion pieces of bellows type are to be protected against mechanical damage.

2.8.7.3 In general, slip type expansion joints are only used for pipes in spaces accessible to operators for inspection during normal navigation. Slip type expansion joints are not to be used for pipes in spaces such as dry cargo tank and deep tank which are not easy to inspect. Slip type expansion joints may be used for pipes in tanks carrying the same liquid as that in the pipes.
Slip type expansion joints are not to be used in the systems listed below:
(1) class I Piping system;
(2) oil (such as fuel oil, lubricating oil, hydraulic oil, thermal oil) pipes of Class II piping system;
(3) steering gear hydraulic system;
(4) starting air and control air system;
(5) boiler feed water system;
(6) fixed gas fire extinguishing system;
(7) bilge pipelines located in cargo hold, deep tanks and double bottom tanks;
(8) cargo oil lines located in pipe duct keels;
(9) oil pipes, such as fuel oil, lubricating oil, hydraulic oil and thermal oil, of Class III systems located in machinery spaces of category A, accommodation spaces or non-mechanically ventilated pipe duct keels;
(10) pipes passing through other tanks;
(11) exhaust system.
For detailed requirements to slip type expansion joints, see relevant provisions in 2.5.3 of Section 5 and Appendix 3 of this Chapter.

2.8.8 Installation of valves and fittings

2.8.8.1 Valves, cocks, pipes or other fittings attached direct to the plating of tanks, and to bulkheads, flats or tunnels which are required to be of watertight construction, are to be secured by means of studs screwed into but not penetrating through the pads welded on the plating. Alternatively, the studs or the bulkhead piece may be welded to the plating.
2.8.8.2 The valves and fittings fitted in engine rooms, boiler rooms, pump rooms and shaft tunnels are to be easily accessible for operation. Where the valves and fittings are situated under the floor plate not easily accessible for operation, they are to be provided with extended operating rods or tools for operation. Furthermore, holes are to be cut in the floor plate under which the valves or fittings are located and to be provided with covers.
2.8.8.3 Where relief valves are fitted in sea water systems, these valves are to be fitted in readily visible positions above the platform. The arrangements are to be such that any discharge from the relief valves will also be readily visible.
2.8.8.4 All valves which are provided with remote control are to be arranged for local manual operation, independent of the remote operating mechanism. Opening and/or closing of the valves by local manual means is not to render the remote control system inoperable.
Sea valves, ship-side valves and valves on collision bulkhead are to be permanently arranged for local manual operation.

2.8.9 Installation of ship-side valves and fittings (other than those on scuppers and sanitary discharges)

2.8.9.1 All sea inlet and overboard discharge pipes are to be fitted with valves or cocks secured direct to the shell plating, or to the plating of fabricated steel sea chests attached to the shell plating. The installation of the valves or cocks is to comply with the following requirements in (1) or (2):
(1) The valves or cocks are to be secured by means of studs screwed into but not penetrating through the pads welded on the shell plating or sea chests.
(2) The valves or cocks may be secured to the distance piece welded on the shell plating or sea chests. The wall thickness of the distance piece is to comply with the requirements in Table 5.3.4.2 of this PART, or may be same as that of the shell plating in way of its penetration into the distance piece. The distance piece is to be adequately strengthened as to ensure its rigidity.
2.8.9.2 All suction and discharge valves and cocks secured direct to the shell plating of the ship are to be fitted with spigots passing through the plating, but the spigots on the valves or cocks may be omitted if these fittings are attached to pads or distance pieces which themselves form spigots in way of the shell plating. Blow-off valves or cocks are also to be fitted with a protection ring through which the spigot is to pass, the ring being on the outside of the shell plating.
2.8.9.3 Blow-off valves or cocks on the ship's side are to be fitted in accessible positions above the level of the working platform, and are to be provided with indicators showing whether they are open or shut.
2.8.9.4 It is to be avoided to locate the overboard discharges in way of the areas where the lifeboats and accommodation ladders are lowered. Where this is not practicable, suitable means are to be provided to

prevent any discharge of water into the lifeboats or onto the accommodation ladders.

2.8.9.5 Sea inlet and overboard discharge valves and cocks are in all cases to be fitted in easily accessible positions and, so far as practicable, are to be readily visible. Indicators are to be provided local to the valves and cocks, showing whether they are open or shut. The operating position of hand wheel or manual operating device of main sea inlet valve is to be situated not less than 450 mm above the lower platform.

If an inlet or outlet pipeline passes through wing tank, the above-mentioned ship-side valve may be installed on inner bulkhead of wing tank. The wall thickness of pipes between inner bulkhead and shell plate of wing tank is to comply with the requirements in Table 5.3.4.2 of this PART, or may be same as that of the shell plating in way of its penetration into the pipes.

2.8.9.6 Gratings are to be fitted at all openings in the ship's side for sea inlet valves and sea chests. The direction of grating bars is to be in line with the length of the ship. The net area through the gratings is not to be less than twice that of the valves connected to the sea inlets, and provision is to be made for clearing the gratings by use of low pressure steam or compressed air.

2.8.9.7 Ship-side valves and fittings as well as sea chests, if made of steel, are to be suitably protected against wastage.

2.8.9.8 Sea chests are to be so arranged as to avoid the formation of air pocket. Where a vent pipe is fitted on the top of the sea chest, a screw-down valve is to be fitted at the root of the vent pipe. The open end of the vent pipe is to be extended to a position above the bulkhead deck or to be led overboard in the vicinity of the bulkhead deck and a ship-side screw-down valve is to be fitted.

2.8.9.9 For sea connections for ships having ice notations, see relevant provisions specified in Chapter 14 of this PART.

Appendix 1 PRODUCTION AND APPLICATION OF PLASTIC PIPING SYSTEMS ON SHIPS①

1.1 Terms and Definitions of this Appendix

1.1.1 "Plastic(s)" means both thermoplastic and thermosetting plastic materials with or without reinforcement, such as PVC and fiber reinforced plastics − FRP. Plastic(s) includes synthetic rubber and materials of similar thermos/mechanical properties.

1.1.2 "Pipes/piping systems" means those made of plastics and include the pipes, fittings, system joints, method of joining and any internal or external liners, coverings and coatings required to comply with the performance criteria.

1.1.3 "Joint" means the location at which two pieces of pipe or a pipe and a fitting are connected together. The joint may be made by adhesive bonding, laminating, welding, flanges and mechanical joints listed in Table 2.5.3.1(1), Chapter 2 of this PART.

1.1.4 "Fittings" means bends, elbows, fabricated branch pieces etc. of plastic materials.

1.1.5 "Nominal pressure" means the maximum permissible working pressure which should be determined in accordance with the requirements in 1.3.1 of this Appendix.

1.1.6 "Design pressure" means the maximum working pressure which is expected under operation conditions or the highest set pressure of any safety valve or pressure relief device on the system, if fitted.

1.1.7 "Fire endurance" means the capability of piping to maintain its strength and integrity (i.e. capable of performing its intended function) for some predetermined period of time while exposed to fire.

1.1.8 "Essential to the safety of ship" means all piping systems that in event of failure will pose a threat to personnel and the ship (piping systems essential to the safety are provided by Table 1.4.1).

1.1.9 "Essential services" are those services essential for propulsion and steering and safety of the ship as specified in 1.1.2, Chapter 1, PART FOUR of the Rules.

1.2 Scope

1.2.1 This Appendix is applicable to piping systems on ships, including pipe joints and fittings, made predominately of other material than metal.

1.2.2 The use of mechanical joints approved for the use in metallic piping systems only are not applicable in this Appendix.

1.2.3 Piping systems intended for non-essential services are to meet only the requirements of recognized standards and 1.3.1(3)②, 1.4.2, 1.5.2~1.5.7 and 1.6 of this Appendix.

1.3 General Requirements

The specification of piping is to be in accordance with a recognized national or international standard acceptable to ISC. In addition, the following requirements apply:

1.3.1 Strength

(1) The strength of the pipes is to be determined by a hydrostatic test failure pressure of a pipe specimen under the standard conditions: atmospheric pressure equal to 0.1 MPa, relative humidity 30%, environmental and carried fluid temperature 298 K (25℃).

(2) The strength of fittings and joints is not to be less than that of the pipes.

(3) The nominal pressure is to be determined from the following conditions:

① Internal Pressure

For an internal pressure, the following is to be taken whichever is smaller:

$$Pn \text{ int } \frac{c}{\lambda} Psth/4 \quad \text{or} \quad Pn \text{ int } \frac{c}{\lambda} Plth/2.5 \text{ where:}$$

Psth — short-term hydrostatic test pipe failure pressure, in MPa;

Plth — long-term hydrostatic test pipe failure pressure (> 100,000 h), in MPa.

② External Pressure(for any installation which may be subject to vacuum conditions inside the pipe or a head of liquid acting on the outside of the pipe; and for any pipe installation required to remain operational in case of flooding damage, as per SOLAS II-1/8-1, or for any pipes that would allow progressive flooding to other compartments through damaged piping or through open ended pipes in the compartments)

For an external pressure:

---

① It is addressed by IACS according to the provisions of IMO resolution A.753(18), as amended by IMO Res. MSC.313(88) and IMO Res. MSC. 399(95).

$$Pn\ ext \leq Pcol/3$$

where: Pcol — pipe collapse pressure, in MPa.

In no case is the pipe collapse pressure to be less than 0.3 MPa.

The maximum working external pressure is a sum of the vacuum inside the pipe and a head of liquid acting on the outside of the pipe.

(4) Notwithstanding the requirements of (3)① or (3)② above as applicable, the pipe or pipe layer minimum wall thickness is to follow recognized standards. In the absence of standards for pipes not subject to external pressure, the requirements of (3)② above are to be met.

(5) The maximum permissible working pressure is to be specified with due regard for maximum possible working temperatures in accordance with manufacturer's recommendations.

1.3.2 Axial Strength

(1) The sum of the longitudinal stresses due to pressure, weight and other loads is not to exceed the allowable stress in the longitudinal direction.

(2) In the case of fiber reinforced plastic pipes, the sum of the longitudinal stresses is not to exceed half of the nominal circumferential stress derived from the nominal internal pressure condition (see 1.3.1 of this Appendix).

1.3.3 Impact Resistance

(1) Plastic pipes and joints are to have a minimum resistance to impact in accordance with recognized national or international standards.

(2) After testing, the specimen is to be tested to a hydraulic pressure equal to 2.5 times the design pressure for at least 1 h.

1.3.4 Temperature

(1) The permissible working temperature depending on the working pressure is to be in accordance with manufacturer's recommendations, but in each case it is to be at least 20℃ lower than the minimum heat distortion/deflection temperature of the pipe material, determined according to ISO 75-2 method A, or equivalent, e.g. ASTMD648-18.

(2) The minimum heat distortion/deflection temperature is not to be less than 80℃.

1.4 Requirements for Pipes/Piping Systems Depending on Service and/or Locations

1.4.1 Fire Endurance

(1) Pipes and their associated joints and fittings whose integrity is essential to the safety of ships, including plastic piping required by SOLAS II-2/21.4 to remain operational after a fire casualty, are required to meet the minimum fire endurance requirements of Appendix 1 or 2, as applicable, of IMO resolution A.753 (18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95).

(2) Unless instructed otherwise by the Administration, fire endurance tests are to be carried out with specimen representative for pipes, joints and fittings[①]:

① Pipes:

- for sizes with outer diameter < 200 mm the minimum outer diameter and wall thickness[②]
- for sizes with outer diameter ≥ 200 mm one test specimen for each category of t/d (D = outer diameter, t = structural wall thickness). A scattering of ±10% for t/D is regarded as the same group. Minimum size approved is equal to the diameter of specimen successfully tested.

② Joints

- Each type of joint applicable for applied fire endurance level tested on pipe to pipe specimen.

(3) Means are to be provided to ensure a constant media pressure inside the test specimen during the fire test as specified in Appendix 1 or 2 of the IMO Res.A.753(18), as amended by IMO Resolutions MSC.313(88) and MSC.399(95). During the test it is not permitted to replace media drained by fresh water or nitrogen.

(4) Depending on the capability of a piping system to maintain its strength and integrity, there exist five different levels of fire endurance for piping systems.

① Level 1: Piping having passed the fire endurance test specified in Appendix 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95) for duration of

---

① A test specimen incorporating several components of a piping system may be tested in a single test.

② Test conditions are most demanding for minimum wall thickness and thus larger wall thickness is covered. A key factor determining the fire performance of a pipe component variant is the thickness-to-diameter (t/D) ratio and whether it is larger or smaller than that of the variant which has been fire-tested. If fire-protective coatings or layers are included in the variant used in the fire test, only variants with the same or greater thickness of protection, regardless of the (t/D) ratio, are to be qualified by the fire test.

a minimum of one hour without loss of integrity in the dry condition is considered to meet level 1 fire endurance standard (L1).

② Level 1W: Piping systems similar to level 1 systems except these systems do not carry flammable fluid or any gas and a maximum 5% flow loss in the system after exposure is acceptable[①], which is considered to meet level 1W fire endurance standard (L1W).

③ Level 2: Piping having passed the fire endurance test specified in Appendix 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95) for a duration of a minimum of 30 min in the dry condition is considered to meet level 2 fire endurance standard (L2).

④ Level 2W: Piping systems similar to level 2 systems except a maximum 5% flow loss in the system after exposure is acceptable[①], which is considered to meet level 2W fire endurance standard (L2W).

⑤ Level 3: Piping having passed the fire endurance test specified in Appendix 2 of IMO resolution A.753(18), as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95) for a duration of a minimum of 30 min in the wet condition is considered to meet level 3 fire endurance standard (L3).

(5) Permitted use of piping depending on fire endurance, location and piping system is given in Table 1.4.1.

(6) For Safe Return to Port purposes (SOLAS II-2/21.4), plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.

1.4.2 Flame Spread

(1) All pipes, except those fitted on open decks and within tanks, cofferdams, pipe tunnels and ducts, if separated from accommodation, permanent manned areas and escape ways by means of an A class bulkhead, are to have low surface flame spread characteristics not exceeding average values listed in Appendix 3 of IMO resolution A.753(18), as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95).

(2) Surface flame spread characteristics are to be determined using the procedure given in the 2010 FTP Code, Annex 1, Part 5 with regard to the modifications due to the curvilinear pipe surfaces as listed in Appendix 3 of IMO Resolution A.753(18), as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95).

(3) Surface flame spread characteristics may also be determined using the test procedures given in ASTM D635, or in other national equivalent standards. Under the procedure of ASTM D635 a maximum burning rate of 60 mm/min applies. In case of adoption of other national equivalent standards, the relevant acceptance criteria are to be defined.

1.4.3 Fire Protection Coatings

Where a fire protective coating of pipes and fittings is necessary for achieving the fire endurance level required, it is to meet the following requirements:

① The pipes are generally to be delivered from the manufacturer with the protective coating on.

② The fire protection properties of the coating are not to be diminished when exposed to salt water, oil or bilge slops. It is to be demonstrated that the coating is resistant to products likely to come into contact with the piping.

③ In considering fire protection coatings, such characteristics as thermal expansion, resistance against vibrations, and elasticity are to be taken into account.

④ The fire protection coatings are to have sufficient resistance to impact to retain their integrity.

1.4.4 Electrical Conductivity

Where electrical conductivity is to be ensured, the resistance of the pipes and fittings is not to exceed 1×10^5 Ω/m.

---

① The flow loss must be taken into account when dimensioning the system.

Notes:

L1—Fire endurance test (Annex 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95)) in dry conditions, 60 min;

L2—Fire endurance test (Annex 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95)) in dry conditions, 30 min;

L3—Fire endurance test (Annex 2 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95)) in wet conditions, 30 min;

L1W—Fire endurance test (see 1.4.1(2) of this Appendix);

L2W—Fire endurance test(see 1.4.1(2) of this Appendix);

O — No fire endurance test required;

NA—Not applicable;

× — Metallic materials having a melting point greater than 925℃.

① Where non-metallic piping is used, remotely controlled valves to be provided at ship's side (valve is to be controlled from outside space).

② Remote closing valves to be provided at the cargo tanks.

③ When cargo tanks contain flammable liquids with f.p. > 60 ℃, "O" may replace "NA" or "×".

④ For drains serving only the space concerned, "O" may replace "L1W".

⑤ When controlling functions are not required in statutory requirements or guidelines, "O" may replace "L1".

⑥ For pipe between machinery space and deck water seal, "O" may replace "L1".

⑦ For passenger vessels, "×" is to replace "L1".

⑧ Scuppers serving open decks in positions 1 and 2, as defined in regulation 13 of the Protocol of 1988 relating to the International Convention on Load Lines, 1966, should be "×" throughout unless fitted at the upper end with the means of closing capable of being operated from a position above the freeboard deck in order to prevent down-flooding.

⑨ For essential services, such as fuel oil tank heating and ship's whistle, "×" is to replace "O".

⑩ For tankers where compliance with paragraph 3.6, regulation 19 of Annex I of MARPOL is required, "NA" is to replace "O".

⑪ L3 in service spaces, NA in accommodation and control spaces.

⑫ Type Approved plastic piping without fire endurance test (0) is acceptable downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire.

⑬ For Passenger Ships subject to SOLAS II-2, Reg.21.4 (Safe return to Port), plastic pipes for services required to remain operative in the part of the ship not affected by the casualty thresholds, such as systems intended to support safe areas, are to be considered essential services. In accordance with MSC Circular MSC.1/Circ.1369, interpretation 12, for Safe Return to Port purposes, plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.

Location Definition:

A —Machinery spaces of category A: Machinery spaces of category A as defined in SOLAS① II-2/3.31.

B—Other machinery spaces: Spaces, other than category A machinery spaces and cargo pump rooms, containing propulsion machinery, boilers, fuel oil units, steam and internal combustion engines, generators and major electrical machinery, pumps, oil filling stations, refrigerating, stabilizing, ventilation and air-conditioning machinery, and similar spaces, and trunks to such spaces.

C—Cargo pump rooms: Spaces containing cargo pumps and entrances and trunks to such spaces.

D—Ro-ro cargo holds: Ro-ro cargo holds are ro-ro cargo spaces and special category spaces as defined in SOLAS① regulation II-2/3.41 and 3.46.

E—Other dry cargo holds: All spaces other than ro-ro cargo holds used for non-liquid cargo and trunks to such spaces.

F—Cargo tanks: All spaces used for liquid cargo and trunks to such spaces.

G—Fuel oil tanks: All spaces used for fuel oil (excluding cargo tanks) and trunks to such spaces.

H—Ballast water tanks: All spaces used for ballast water and trunks to such spaces.

I— Cofferdams, voids, etc.: Cofferdams and voids are those empty spaces between two bulkheads separating two adjacent compartments.

J—Accommodation and service spaces: Accommodation spaces, service spaces and control stations as defined in SOLAS①

① SOLAS Chapter II-2.

regulation II-2/3.1, 3.45, 3.18.
K—Open decks: Open deck spaces as defined in SOLAS① regulation II-2/9.2.2.3.2(5).

1.5 *Material Approval and Quality Control During Manufacture*

1.5.1 Except as required in 1.2.3 of this Appendix, Prototypes of pipes and fittings are to be tested to determine short-term and long-term design strength, fire endurance and low surface flame spread characteristics (if applicable), electrical resistance (for electrically conductive pipes), impact resistance in accordance with this Appendix.

1.5.2 For prototype testing, representative samples of pipes and fittings are to be selected to the satisfaction of ISC.

1.5.3 The manufacturer is to have quality system that meets ISO 9000 series standards or equivalent.

The quality system is to consist of elements necessary to ensure that pipes and fittings are produced with consistent and uniform mechanical and physical properties.

1.5.4 Each pipe and fitting is to be tested by the manufacturer at a hydrostatic pressure not less than 1.5 times the nominal pressure. Alternatively, for pipes and fittings not employing hand lay-up techniques, the hydrostatic pressure test may be carried out in accordance with the hydrostatic testing requirements stipulated in the recognized national or international standard accepted by ISC to which the pipe or fittings are manufactured, provided that there is an effective quality system in place.

1.5.5 Pipes and fittings are to be permanently marked with identification. Identification is to include pressure ratings, the design standards that the pipe or fitting is manufactured in accordance with, and the material of which the pipe or fitting is made.

1.5.6 In case the manufacturer does not have an approved quality system complying with ISO 9000 series or equivalent, pipes and fittings are to be tested in accordance with this Appendix to the satisfaction of the Surveyors for every batch of pipes.

1.5.7 Depending upon the intended application, ISC may require the pressure testing of each pipe and/or fitting.

1.6 *Installation*

1.6.1 Supports

(1) Selection and spacing of pipe supports in shipboard systems are to be determined as a function of allowable stresses and maximum deflection criteria. Support spacing is not to be greater than the pipe manufacturer's recommended spacing. The selection and spacing of pipe supports are to take into account pipe dimensions, pipe length, mechanical and physical properties of the pipe material, mass of pipe and contained fluid, external pressure, operating temperature, thermal expansion effects, loads due to external forces, thrust forces, water hammer, vibrations, maximum accelerations to which the system may be subjected. Combination of loads is to be considered.

(2) Each support is to evenly distribute the load of the pipe and its contents over the full width of the support. Measures are to be taken to minimize wear of the pipes where they contact the supports.

(3) Heavy components in the piping system such as valves and expansion joints are to be independently supported.

1.6.2 Expansion

(1) Suitable provision is to be made in each pipeline to allow for relative movement between pipes made of plastic and the steel structure, having due regard to:

① the difference in the coefficients of thermal expansion;

② deformations of the ship's hull and its structure.

(2) When calculating the thermal expansions, account is to be taken of the system working temperature and the temperature at which assembly is performed.

1.6.3 External Loads

(1) When installing the piping, allowance is to be made for temporary point loads, where applicable. Such allowances are to include at least the force exerted by a load (person) of 100 kg at mid-span on any pipe of more than 100 mm nominal outside diameter.

(2) Besides for providing adequate robustness for all piping including open-ended piping a minimum wall thickness, complying with 1.3.1 of this Appendix, may be increased taking into account the conditions encountered during service on board ships.

(3) Pipes are to be protected from mechanical damage where necessary.

1.6.4 Strength of Connections

(1) The strength of connections is not to be less than that of the piping system in which they are installed.

(2) Pipes may be assembled using adhesive-bonded, welded, flanged or other joints.

(3) Adhesives, when used for joint assembly, are to be suitable for providing a permanent seal between the

pipes and fittings throughout the temperature and pressure range of the intended application.
(4) Tightening of joints is to be performed in accordance with manufacturer's instructions.

1.6.5 Installation of Conductive Pipes

(1) In piping systems for fluids with conductivity less than 1,000 pS/m, such as refined products and distillates use is to be made of conductive pipes.
(2) Regardless of the fluid being conveyed, plastic piping is to be electrically conductive if the piping passes through a hazardous area. The resistance to earth from any point in the piping system is not to exceed 1×10^6 Ω/m. It is preferred that pipes and fittings be homogeneously conductive. Pipes and fittings having conductive layers are to be protected against a possibility of spark damage to the pipe wall. Satisfactory earthing is to be provided.
(3) After completion of the installation, the resistance to earth is to be verified. Earthing wires are to be accessible for inspection.

1.6.6 Application of Fire Protection Coatings

(1) Fire protection coatings are to be applied on the joints, where necessary for meeting the required fire endurance as for 1.4.3 of this Appendix, after performing hydrostatic pressure tests of the piping system.
(2) The fire protection coatings are to be applied in accordance with manufacturer's recommendations, using a procedure approved in each particular case.

1.6.7 Penetration of Divisions

(1) Where plastic pipes pass through A or B class divisions, arrangements are to be made to ensure that the fire endurance is not impaired. These arrangements are to be tested in accordance with Recommendations for fire test procedures for A, B and F bulkheads 2010 FTP Code, annex 1, part 3 (Res. MSC.307(88) as amended by Res.MSC.437(99)).
(2) When plastic pipes pass through watertight bulkheads or decks, the watertight integrity of the bulkhead or deck is to be maintained. For pipes not able to satisfy the requirements in 1.3.1(3)② of this Appendix, a metallic shut-off valve operable from above the freeboard deck should be fitted at the bulkhead or deck.
(3) If the bulkhead or deck is also a fire division and destruction by fire of plastic pipes may cause the inflow of liquid from tanks, a metallic shut-off valve operable from above the freeboard deck should be fitted at the bulkhead or deck.

1.6.8 Control during Installation

(1) Installation is to be in accordance with the manufacturer's guidelines.
(2) Prior to commencing the work, joining techniques are to be approved.
(3) The tests and examinations specified in this Appendix are to be completed before shipboard piping installation commences.
(4) The personnel performing this work are to be properly qualified and certified to the satisfaction of ISC.
(5) The procedure of making bonds is to include:

① materials used;
② tools and fixtures;
③ joint preparation requirements;
④ cure temperature;
⑤ dimensional requirements and tolerances;
⑥ tests acceptance criteria upon completion of the assembly.

(6) Any change in the bonding procedure which will affect the physical and mechanical properties of the joint is to require the procedure to be re-qualified.

1.6.9 Bonding Procedure Quality Testing

(1) A test assembly is to be fabricated in accordance with the procedure to be qualified and it is to consist of at least one pipe-to-pipe joint and one pipe-to-fitting joint.
(2) When the test assembly has been cured, it is to be tested to a hydraulic pressure equal to 2.5 times the design pressure for at least 1 h. No leakage or separation of joints is allowed. The test is to be conducted so that the joint is loaded in both longitudinal and circumferential directions.
(3) Selection of the pipes used for test assembly, is to be in accordance with the following:

① When the largest size to be joined is 200 mm nominal outside diameter, or smaller, the test assembly is to be the largest piping size to be joined.
② When the largest size to be joined is greater than 200 mm nominal outside diameter, the size of the test assembly is to be either 200 mm or 25% of the largest piping size to be joined, whichever is greater.

(4) When conducting performance qualifications, each bonder and each bonding operator are to make up test assemblies, the size and number of which are to be as required above.

1.6.10 Testing after Installation on Board

(1) Piping systems for essential services are to be tested to a pressure equal to 1.5 times the design pressure or 0.4 MPa, whichever is greater. Notwithstanding the requirement above, the requirement in 1.6.10(2) may be applied to open ended pipes (drains, effluent, etc.).
(2) Piping systems for non-essential services are to be checked for leakage under operational conditions.
(3) For piping required to be electrically conductive, earthing is to be checked and random resistance testing is to be conducted.

1.7 *Test specification for plastic pipes*

1.7.1 General requirements

1.7 contains requirements for the type approval of plastic pipes. It is applicable to piping systems, including pipe joints and fittings, made predominately of other material than metal.

1.7.2 Documentation

The following information for the plastic pipes, fittings and joints is to be submitted for consideration and approval:

(1) General information:

① Pipe and fitting dimensions;
② Maximum internal and external working pressure;
③ Working temperature range;
④ Intended services and installation locations;
⑤ The level of fire endurance;
⑥ Electrically conductive;
⑦ Intended fluids;
⑧ Limits on flow rates;
⑨ Serviceable life;
⑩ Installation instructions;
⑪ Details of marking.

(2) Drawings and supporting documentation:

① Certificates and reports for relevant tests previously carried out;
② Details of relevant standards;
③ All relevant design drawings, catalogues, data sheets, calculations and functional descriptions;
④ Fully detailed sectional assembly drawings showing pipe, fittings and pipe connections.

(3) Materials(as applicable):

① The resin type;
② Catalyst and accelerator types, and concentration employed in the case of reinforced polyester resin pipes or hardeners where epoxide resins are employed;
③ A statement of all reinforcements employed where the reference number does not identify the mass per unit area or the tex number of a roving used in a filament winding process, these are to be detailed;
④ Full information regarding the type of gel-coat or thermoplastic liner employed during construction, as appropriate;
⑤ Cure / post-cure conditions. The cure and post-cure temperatures and times employ resin / reinforcement ratio;
⑥ Winding angle and orientation.
⑦ Joint bonding procedures and qualification tests results, see 1.6.8(5) of this Appendix.

1.7.3 Testing

Testing is to demonstrate compliance of the pipes, fittings and joints for which type approval is sought with the requirement of this Appendix.

Pipes, joints and fittings are to be tested for compliance with the requirements of standards① acceptable to ISC.

① For the list of standards refer to IACS Recommendation No.86.

Appendix 2 FLEXIBLE HOSES

1.1 *Definition*

1.1.1 Flexible hose assembly① means short length of metallic or non-metallic hose normally with prefabricated end fittings ready for installation.

Note: Flexible hose assemblies for essential services or containing either flammable or toxic media are not to exceed 1.5 m in length.

1.2 *Scope*

1.2.1 This Appendix applies to flexible hoses of metallic or non-metallic material intended for a permanent connection between a fixed piping system and items of machinery. This Appendix may also be applied to temporary connected flexible hoses or hoses of portable equipment.

1.2.2 Flexible hose assemblies satisfying the requirements of this Appendix may be accepted for use in oil fuel, lubricating, hydraulic and thermal oil systems, fresh water and sea water cooling systems, compressed air systems, bilge and ballast systems and Class III steam systems. Flexible hoses in high pressure fuel oil injection systems are not to be accepted.

1.2.3 This Appendix is not applicable to hoses intended to be used in fixed fire extinguishing systems.

1.3 *Design and construction*

1.3.1 Flexible hoses constructed of rubber materials and intended for use in bilge, ballast, compressed air, oil fuel, lubricating, hydraulic and thermal oil systems are to incorporate a single, double or more, closely woven integral wire braid or other suitable material reinforcement.

Flexible hoses of plastics materials for the same purposes, such as Teflon or Nylon, which are unable to be reinforced by incorporating closely woven integral wire braid are to have suitable material reinforcement as far as practicable.

Where rubber or plastics materials hoses are to be used in oil supply lines to burners, the hoses are to have external wire braid protection in addition to the reinforcement mentioned above. Flexible hoses for use in steam systems are to be of metallic construction.

1.3.2 Flexible hoses are to be complete with approved end fittings in accordance with manufacturer's specification. The end connections that do not have a flange are to comply with the requirements of 2.5.3 of this Chapter as applicable and each type of hose/fitting combination is to be subject to prototype testing to the same standard as that required by the hose with particular reference to pressure and impulse tests.

1.3.3 The use of hose clamps and similar types of end attachments is not acceptable for flexible hoses in piping systems for steam, flammable media, starting air systems or for sea water systems where failure may result in flooding.

In other piping systems, the use of hose clamps may be accepted where the working pressure is less than 0.5 MPa and provided there are double clamps at each end connection.

1.3.4 Flexible hose assemblies intended for installation in piping systems where pressure pulses and/or high levels of vibration are expected to occur in service, are to be designed for the maximum expected impulse peak pressure and forces due to vibration. The tests required by 1.5 of this Appendix are to take into consideration the maximum anticipated in-service pressures, vibration frequencies and forces due to installation.

1.3.5 The following flexible hose assemblies constructed of non-metallic materials are to be of fire-resistant type②, except in cases where such hoses are installed on open decks, as defined in SOLAS regulation II-2/9.2.3.3.2.2(10) as amended by IMO resolutions up to MSC.421(98) and not used for fuel oil lines:

(1) used for flammable media;

(2) used for sea water systems where failure may result in flooding.

1.3.6 Flexible hose assemblies are to be selected for the intended location and application taking into consideration ambient conditions, compatibility with fluids under working pressure and temperature conditions.

1.4 *Installation*

1.4.1 In general, flexible hoses are to be limited to a length necessary to provide for relative movement between fixed and flexibly mounted items of machinery/equipment or systems.

---

① Flexible hoses are to be designed and manufactured according to the recognized national or international standards.

② Fire resistance is to be demonstrated by testing to ISO 15540 and ISO 15541.

1.4.2 Flexible hose assemblies are not to be installed where they may be subjected to torsion deformation (twisting) under normal operating conditions.
1.4.3 The number of flexible hoses, in piping systems mentioned in 1.2.2 is to be kept to minimum and to be limited for the purpose stated in 1.2.1.
1.4.4 Where flexible hoses are intended to be used in piping systems conveying flammable fluids that are in close proximity of heated surfaces the risk of ignition due to failure of the hose assembly and subsequent release of fluids is to be mitigated as far as practicable by the use of screens or other similar protection.
1.4.5 Flexible hoses are to be installed in clearly visible and readily accessible locations.
1.4.6 The installation of flexible hose assemblies is to be in accordance with the manufacturer's instructions and use limitations with particular attention to the following:
(1) orientation;
(2) end connection support (where necessary);
(3) avoidance of hose contact that could cause rubbing and abrasion;
(4) minimum bend radii.

1.5 *Tests*

1.5.1 Acceptance of flexible hose assemblies is subject to satisfactory prototype testing. Prototype test programs for flexible hose assemblies are to be submitted for approval and are to be sufficiently detailed to demonstrate performance in accordance with the specified standards.
1.5.2 The tests are, as applicable, to be carried out on different nominal diameters of hose type complete with end fittings for pressure, burst, impulse resistance and fire resistance in accordance with the requirements of the relevant standard①.
Note:
Prototype tests are to be carried out for each size of hose assembly. However, for ranges with more than 3 different diameters, the prototype tests are to be carried out for at least:
(1) the smallest diameter,
(2) the largest diameter,
(3) Intermediate diameters selected based on the principle that prototype tests carried out
for a hose assembly with a diameter D are considered valid only for the diameters ranging between 0.5 D and 2 D.
For fire resistance tests the specimens shall be selected in accordance with ISO 15540.
1.5.3 All flexible hose assemblies are to be satisfactorily prototype burst tested to an international standard② to demonstrate they are able to withstand a pressure not less than four times its design pressure without indication of failure or leakage.

1.6 *Marking*

1.6.1 Flexible hoses are to be permanently marked with the following details:
(1) hose manufacturer's name or trademark;
(2) date of manufacture (month / year);
(3) designation type reference;
(4) nominal diameter;
(5) pressure rating;
(6) temperature rating.
Where a flexible hose assembly is made up of items from different manufacturers, the components are to be clearly identified and traceable to evidence of prototype testing.

---

① The following standards are to be used as applicable:
(1) ISO 6802 – Rubber and plastics hoses and hose assemblies with wire reinforcements – Hydraulic impulse test with flexing;
(2) ISO 6803 – Rubber or plastics hoses and hose assemblies with wire reinforcements 15 test without flexing;
(3) ISO 15540 – Ships and marine technology – Fire resistance of hose assemblies – Test methods;
(4) ISO 15541 – Ships and marine technology – Fire resistance of hose assemblies – Requirements for test bench;
(5) ISO 10380 – Pipework – Corrugated metal hoses and hose assemblies.

② The international standards, e.g. EN or SAE for burst testing of non-metallic hoses, require the pressure to be increased until burst without any holding period at 4 × MWP.

Appendix 3 TYPE APPROVAL OF MECHANICAL JOINTS

1.1 *General*

1.1.1 This Appendix describes the type testing condition for type approval of mechanical joints intended for use in marine piping systems. Conditions outlined in these requirements are to be fulfilled before Type Approval Certificates are issued.

Alternative testing in accordance with national or international standards may also be accepted.

1.2 *Scope*

1.2.1 This Appendix is applicable to mechanical joints defined in 2.5.3 of this Chapter, including compression couplings and slip-on joints of different types for marine use.

1.3 *Documentation*

1.3.1 Following documents and information are to be submitted by manufacturer for assessment and/or approval:

(1) product quality assurance system implemented;

(2) complete description of the product;

(3) typical sectional drawings with all dimensions necessary for evaluation of joint design;

(4) complete specification of materials used for all components of the assembly;

(5) proposed test procedure as required in 1.5 of this Appendix and corresponding test reports or other previous relevant tests;

(6) initial information:

① maximum design pressures (pressure and vacuum);

② maximum and minimum design temperatures;

③ conveyed media;

④ intended services;

⑤ maximum axial, lateral and angular deviation, allowed by manufacturer;

⑥ installation details.

1.4 *Materials*

1.4.1 The materials used for mechanical joints are to comply with the requirements of 2.5.3.3 of this Chapter.

1.4.2 The manufacturer has to submit evidence to substantiate that all components are adequately resistant to working the media at design pressure and temperature specified.

1.5 *Testing, procedures and requirements*

The aim of tests is to demonstrate ability of the pipe joints to operate satisfactory under intended service conditions. The scope and type of tests to be conducted (e.g. applicable tests), sequence of testing, and the number of specimen, is subject to approval and will depend on joint design and its intended service in accordance with the requirements of this Appendix.

Unless otherwise specified, the water or oil as test fluid is to be used.

1.5.1 Test program

Testing requirements for mechanical joints are to be as indicated in Table 1.5.1.

1.5.2 Selection of test specimen

Test specimens are to be selected from production line or at random from stock.

Where there is a variety of size of joints requiring approval, a minimum of three separate sizes, representative of the range, from each type of joint to be tested in accordance with Table 1.5.1 are to be selected.

1.5.3 Mechanical Joint Assembly

Assembly of mechanical joints should consist of components selected in accordance with 1.5.2 and the pipe sizes appropriate to the design of the joints.

Where pipe material would affect the performance of mechanical joints, the selection of joints for testing is to take the pipe material into consideration.

Where not specified, the length of pipes to be connected by means of the joint to be tested is to be at least five times the pipe diameter. Before assembling the joint, conformity of components to the design requirements, is to be verified. In all cases the assembly of the joint is to be carried out only according to he manufacturer's instructions. No adjustment operations on the joint assembly, other than that specified by

the manufacturer, are permitted during the test.

Test Procedures of Mechanical Joints *Table 1.5.1*

Tests		Types of Mechanical Joints			Notes and references
		Compression couplings and pipes unions	Slip-on joints		
			Grip type & slip type machined grooved type	Slip type	
1	Tightness test	×	×	×	1.5.5(1)
2	Vibration (fatigue) test	×	×	–	1.5.5(2)
3	Pressure pulsation test①	×	×	–	1.5.5(3)
4	Burst pressure test	×	×	×	1.5.5(4)
5	Pull-out test	×	×	–	1.5.5(5)
6	Fire endurance test	×	×	×	1.5.5(6), if required by 2.5.3.7 of this Chapter
7	Vacuum test	×③	×	×	1.5.5(7), for suction lines only
8	Repeated assembly test	×②	×	–	1.5.5(8)

Abbreviations: × test is required
– test is not required

Notes:

① For use in those systems where pressure pulsation other than water hammer is expected.

② Except press type and swage type.

③ Except joints with metal-to-metal tightening surface.

1.5.4 Test results acceptance criteria

Where a mechanical joint assembly does not pass all or any part of the tests in Table 1.5.1, two assemblies of the same size and type that failed are to be tested and only those tests which mechanical joint assembly failed in the first instance, are to be repeated. In the event where one of the assemblies fails the second test, that size and type of assembly is to be considered unacceptable.

The methods and results of each test are to be recorded and reproduced as and when required.

1.5.5 Methods of tests

(1) Tightness test

In order to ensure correct assembly and tightness of the joints, all mechanical joints are to be subject to a tightness test, as follows:

① Mechanical joint assembly test specimen is to be connected to the pipe or tubing in accordance with the requirements of 1.5.3 and the manufacturer's instructions, filled with test fluid and de-aerated.
Mechanical joints assemblies intended for use in rigid connections of pipe lengths, are not to be longitudinally restrained.
Pressure inside the joint assembly is to be slowly increased to 1.5 times of design pressure. This test pressure is to be retained for a minimum period of 5 min.
In the event where there is a drop in pressure or there is visual indication of leakage, the test (including fire test) is to be repeated for two test pieces. Where one test piece fails in the repeat test, the coupling will be regarded as having failed.
Other alternative tightness test procedure, such as pneumatic test, may be accepted.

② For compression couplings, a static gas pressure test is to be carried out to demonstrate the integrity of the mechanical joints assembly for tightness under the influence of gaseous media. The pressure is to be raised to maximum pressure or 7.0 MPa, whichever is less.

③ Where the tightness test is carried out using gaseous media as permitted in ① above, then the static pressure test mentioned in ② above need not be carried out.

(2) Vibration (fatigue) test

In order to establish the capability of the mechanical joint assembly to withstand fatigue, which is likely to occur due to vibrations under service conditions, mechanical joints assembly is to be subject to the following vibration test.

Conclusions of the vibration tests should show no leakage or damage.

① Testing of compression couplings and pipe unions
Compression couplings and pipe unions intended for use in rigid pipe connections are to be tested in accordance with this method described as follows.
Rigid connections are joints, connecting pipe length without free angular or axial movement.
Two lengths of pipe is to be connected by means of the joint to be tested. One end of the pipe is to be rigidly fixed while the other end is to be fitted to the vibration rig. The test rig and the joint assembly specimen being tested is to be arranged as shown in Figure 1.

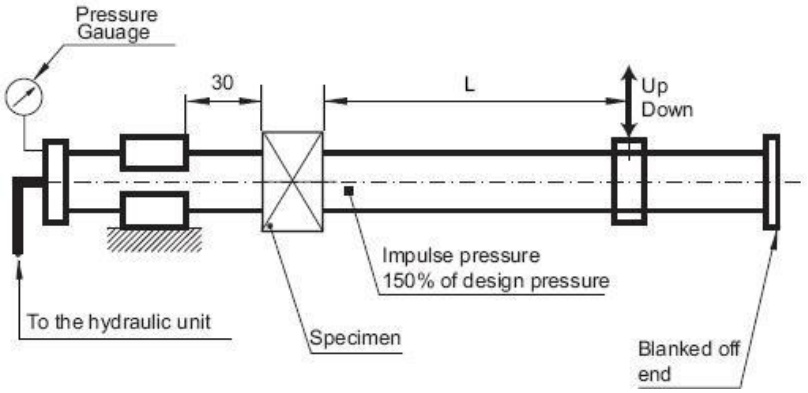

Figure 1

The assembly is to be filled with test fluid, de-aerated and pressurized to the design pressure of the joint.
Pressure during the test is to be monitored. In the event of drop in the pressure and visible leakage, the test is to be repeated as described in 1.5.4 of this Appendix.
Visual examination of the joint assembly is to be carried out.
Re-tightening may be accepted once during the first 1,000 cycles.
Vibration amplitude is to be within 5% of the value calculated from the following formula:

$$A = \frac{2SL^2}{3ED}$$

where: A – single amplitude, in mm;
L – length of the pipe, in mm;
S – allowable bending stress in N/mm^2 based on 0.25 of the yield stress;
E – modulus of elasticity of tube material (for mild steel, E = 210 kN/mm^2);
D – outside diameter of tube, in mm.

Test specimen is to withstand not less than 10^7 cycles with frequency 20 to 50 Hz without leakage or damage.

② Grip type and machine grooved type joints

Grip type joints and other similar joints containing elastic elements are to be tested in accordance with the following method.
A test rig of cantilever type used for testing fatigue strength of components may be used. The test specimen being tested is to be arranged in the test rig as shown in Figure 2.

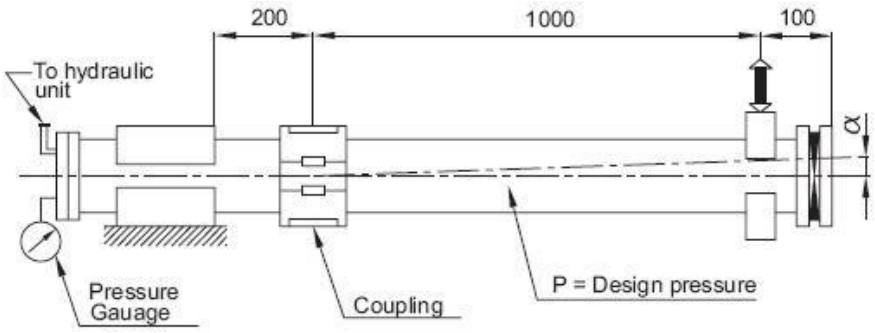

Figure 2

Two lengths of pipes are to be connected by means of joint assembly specimen to be tested. One end of the pipe is to be rigidly fixed while the other end is to be fitted to the vibrating element on the rig. The length of pipe connected to the fixed end should be kept as short as possible and in no case exceeds 200 mm.
Mechanical joint assemblies are not to be longitudinally restrained.
The assembly is to be filled with test fluid, de-aerated and pressurized to the design pressure of the

joint. Preliminary angle of deflection of pipe axis is to be equal to the maximum angle of deflection, recommended by the manufacturer. The amplitude is to be measured at 1 m distance from the center line of the joint assembly at free pipe end connected to the rotating element of the rig (see Figure 2). Parameters of testing are to be as indicated in the table below and to be carried out on the same assembly:

Number of cycles	Amplitude, in mm	Frequency, in Hz
3×10^6	± 0.06	100
3×10^6	± 0.5	45
3×10^6	± 1.5	10

Pressure during the test is to be monitored. In the event of a drop in the pressure or visible leakage, the test is to be repeated as described in 1.5.4 of this Appendix.

Visual examination of the joint assembly is to be carried out.

(3) Pressure pulsation test

In order to determine capability of mechanical joint assembly to withstand pressure pulsation likely to occur during working conditions, joint assemblies intended for use in rigid connections of pipe lengths, are to be tested in accordance with the following method.

The mechanical joint test specimen for carrying out this test may be the same as that used in the test in 1.5.5(1) provided it passed that test.

The vibration test in 1.5.5(2) and the pressure pulsation test are to be carried out simultaneously for compression couplings and pipe unions.

The mechanical joint test specimen is to be connected to a pressure source capable of generating pressure pulses of magnitude as shown in Figure 3.

Impulse pressure is to be raised from 0 to 1.5 times the design pressure of the joint with a frequency equal to 30 to 100 cycles per minute. The number of cycles is not to be less than 5×10^5.

The mechanical joint is to be examined visually for sign of leakage or damage during the test.

(4) Burst pressure test

In order to determine the capability of the mechanical joint assembly to withstand a pressure as stated by 2.5.3.8 of this Chapter, the following burst test is to be carried out.

Mechanical joint test specimen is to be connected to the pipe or tubing in accordance with the requirements of 1.5.3, filled with test fluid, de-aerated and pressurized to test pressure with an increasing rate of 10% per minute or test pressure. The mechanical joint assembly intended for use in rigid connections of pipe lengths is not to be longitudinally restrained.

Duration of this test is not to be less than 5 min at the maximum pressure. This pressure value is to be in compliance with the requirements of 2.5.3.8 of this Chapter.

Where considered convenient, the mechanical joint test specimen used in tightness test in 1.5.5(1) may be used for the burst test provided it passed the tightness test.

The specimen may have small deformation whilst under test pressure, but no leakage or visible cracks are permitted.

(5) Pull-out test

In order to determine ability of a mechanical joint assembly to withstand axial load likely to be encountered in service without the connecting pipe from becoming detached, following pull-out test is to be carried out.

Pipes of suitable length are to be fitted to each end of the mechanical joints assembly test specimen. The test specimen is to be pressurized to design pressure. When pressure is attained, an external axial load is to be imposed with a value calculated by the following formula:

$$L = \frac{\pi}{4} D^2 p$$

where: D – pipe outside diameter, in mm;

p – design pressure, in N/mm^2;

L – applied axial load, in N.

The pressure and axial load are to be maintained for a period of 5 min.

During the test, pressure is to be monitored and relative movement between the joint assembly and the pipe is to be measured.

The mechanical joint assembly is to be visually examined for drop in pressure and signs of leakage or damage.

There are to be no movement between mechanical joint assembly and the connecting pipes.

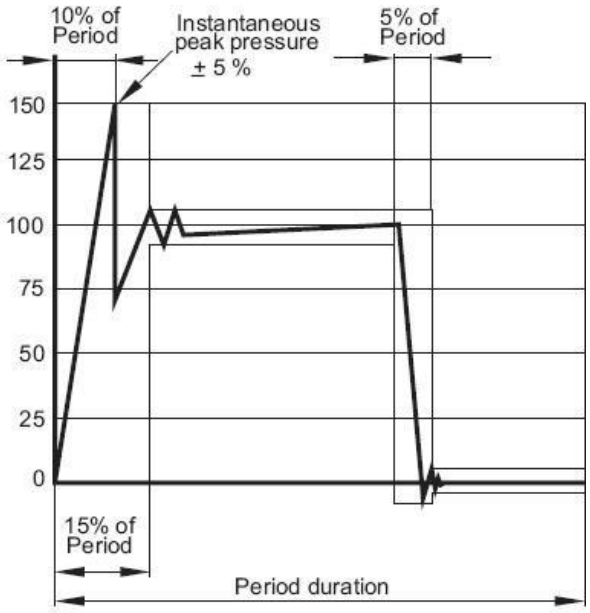

Figure 3 Impulse pressure diagram

(6) Fire endurance test

In order to establish capability of the mechanical joints to withstand effects of fire which may be encountered in service, mechanical joints are to be subjected to a fire endurance test. The fire endurance test is to be conducted on the selected test specimens as per the following standards.

① ISO 19921: Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Test methods.

② ISO 19922: Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Requirements imposed on the test bench.

Clarifications to the standard requirements in ISO19921, Paragraphs 7.2, 7.4, 7.6 and 7.7:

① If the fire test is conducted with circulating water at a pressure different from the design pressure of the joint (however of at least 5 bar), the subsequent pressure test is to be carried out to 1.5 times the design pressure.

② If the fire test is required in Table 2.5.3.1(2) to be "8 min dry + 22 min wet" or "30 min dry", i.e. conducted for a period of time without circulating of water, the following test conditions apply:

Test condition "8 min dry + 22 min wet"

The test piece is not required to be rinsed with the test medium (water) in preparation for the test as required in Paragraph 7.2 of ISO 19921. The exposure to fire is to be started and continued for 8 minutes with the sample dry; after 8 minutes of dry test condition the piping system is to be filled with water and test pressure is to be increased up to at least 5 bar within 2 minutes, then maintained to at least 5 bar. After further 22 minutes (i.e. 30 minutes from initial exposure to fire) the exposure to fire is to be stopped and a hydrostatic pressure test as specified in ① is to be carried out.

Test condition "30 min dry"

The exposure to fire is to be started and continued for 30 minutes with the sample dry. After 30 minutes the exposure to fire is to be stopped and a hydrostatic pressure test as specified in ① is to be carried out.

Note:

For fire tests in dry condition the pressure inside the test specimen is to be monitored for a rise due to heating of the enclosed air. Means of pressure relief should be provided where deemed necessary.

High pressures created during this test can result in failure of the test specimen. Precautions shall be taken to protect personnel and facilities.

Paragraph 7.5 of ISO 19921 does not apply to the dry tests and no forced air circulation is to be arranged.

For fire endurance test requiring exposure time greater than 30 minutes test conditions are adjusted to meet the extended required total exposure time. In all cases for dry-wet test the minimum dry test exposure time is 8 minutes.

③ A selection of representative nominal bores may be tested in order to evaluate the fire resistance of a series or range of mechanical joints of the same design. When a mechanical joint of a given nominal bore (D_n) is so tested then other mechanical joints falling in the range D_n to $2 \times D_n$ (both inclusive) are considered accepted.

④ Alternative test methods and/or test procedures considered to be at least equivalent may be accepted in cases where the test pieces are too large for the test bench and cannot be completely enclosed by the flames.

⑤ Where thermal insulation is acceptable as a means of providing fire resistance, following requirements apply:

a. Thermal insulation materials applied on couplings are to be non-combustible according to ISO 1182 as required by the Fire Test Procedures Code defined in Regulation 3 of SOLAS Chapter II-2 as amended by IMO resolutions up to MSC.421(98).
Precautions are to be taken to protect the insulation from being impregnated with flammable oils.

b. At least the fire endurance and the vibration testing in Table 1.5.1 are to be carried out with thermal insulation in place.

c. A service restriction is to be stated on the type approval certificate that the mechanical joints are to be fitted with thermal insulation during the installation in cases where the mechanical joints are used where fire resistance is required, unless mechanical joints are delivered already fitted with thermal insulation before installation.

(7) Vacuum test

In order to establish capability of mechanical joint assembly to withstand internal pressures below atmosphere, similar to the conditions likely to be encountered under service conditions, following vacuum test is to be carried out.

Mechanical joint assembly is to be connected to a vacuum pump and subjected to a pressure 0.0170 MPa absolute. Once this pressure is stabilized, the test specimens under test are to be isolated from the vacuum pump and this pressure is to be maintained for a period of 5 min.

No internal pressure rise is permitted.

(8) Repeated assembly test

Mechanical joint test specimens are to be dismantled and reassembled 10 times in accordance with manufacturer's instructions and then subject to a tightness test as defined in 1.5.5(1).

Appendix 4 AIR PIPE CLOSING DEVICES

1.1 *General requirements*

1.1.1 Where air pipes are required by the Rules or the International Convention on Load Lines, 1966 or the Protocol of 1988 relating to the International Convention on Load Lines, 1966 to be fitted with automatic closing devices, they are to comply with the following.

1.2 *Design*

1.2.1 Air pipe automatic closing devices are to be so designed that they will withstand both ambient and working conditions, and be suitable for use at inclination up to and including ±40°.

1.2.2 Air pipe automatic closing devices are to be constructed to allow inspection of the closure and the inside of the casing as well as changing the seals.

1.2.3 Efficient ball or float seating arrangements are to be provided for the closures. Bars, cage or other devices are to be provided to prevent the ball or float from contacting the inner chamber in its normal state and made in such a way that the ball or float is not damaged when subjected to water impact due to a tank being overfilled.

1.2.4 Air pipe automatic closing devices are to be self-draining.

1.2.5 The clear area through an air pipe closing device in the open position is to be at least equal to the area of the inlet.

1.2.6 An automatic closing device is to:

(1) prevent the free entry of water into the tank;

(2) allow the passage of air or liquid to prevent excessive pressure or vacuum coming on the tank.

1.2.7 In the case of air pipe closing devices of the float type, suitable guides are to be provided to ensure unobstructed operation under all working conditions of heel and trim as specified in 1.2.1 of this Appendix.

1.2.8 The maximum allowable tolerances for wall thickness of floats are not to exceed ±10% of thickness.

1.2.9 The inner and the outer chambers of an automatic air pipe head is to be of a minimum thickness of 6 mm. Where side covers are provided and their function is integral to providing functions of the closing device as outlined in 1.2.6 of this Appendix, they are to have a minimum wall thickness of 6 mm. Where the air pipe head meets the tightness test in 1.4.1(2) of this Appendix without the side covers attached, such side covers are not considered to be integral to the closing device, in which case their wall thickness less than 6 mm may be acceptable.

1.3 *Materials*

1.3.1 Casings of air pipe closing devices are to be of approved metallic materials adequately protected against corrosion.

1.3.2 For galvanized steel air pipe heads, the zinc coating is to be applied by the hot method and the thickness is to be 70 to 100 μm.

1.3.3 For areas of the head susceptible to erosion (e.g. those parts directly subjected to ballast water impact when the tank is being pressed up, for example the inner chamber area above the air pipe, plus an overlap of 10° or more either side) an additional harder coating should be applied. This is to be an aluminum bearing epoxy, or other equivalent, coating, applied over the zinc.

1.3.4 Closures and seats made of non-metallic materials are to be compatible with the media intended to be carried in the tank and to seawater and suitable for operating at ambient temperatures between -25℃ and 85℃.

1.4 *Type testing*

1.4.1 Testing of air pipe automatic closing devices

Each type and size of air pipe automatic closing device is to be surveyed and type tested at the manufacturer's works or other acceptable location according to ISC' practice. The minimum test requirements for an air pipe automatic closing device are to include the following:

(1) Determination of the flow characteristics

The flow characteristics of the air pipe closing device are to be determined. Measuring of the pressure drop versus rate of volume flow is to be carried out using water and with any intended flame or insect screens in place.

(2) Tightness test during immersion/emerging in water

An automatic closing device is to be subject to a series of tightness tests involving not less than two immersion cycles under each of the following conditions:

① The automatic closing device is to be submerged slightly below the water surface at a velocity of approximately 4 m/min and then returned to the original position immediately. The quantity of leakage is to be recorded.

② The automatic closing device is to be submerged to a point slightly below the surface of the water. The submerging velocity is to be approximately 8 m/min and the air pipe vent head is to remain submerged for not less than 5 min. The quantity of leakage is to be recorded.

③ Each of the above tightness tests is to be carried out in the normal position as well as at an inclination of 40 degrees under the strictest conditions for the device. In cases where such strictest conditions are not clear, tests are to be carried out at an inclination of 40 degrees with the device opening facing in three different directions: upward, downward, sideways (left or right), see Figures 1 to 4.

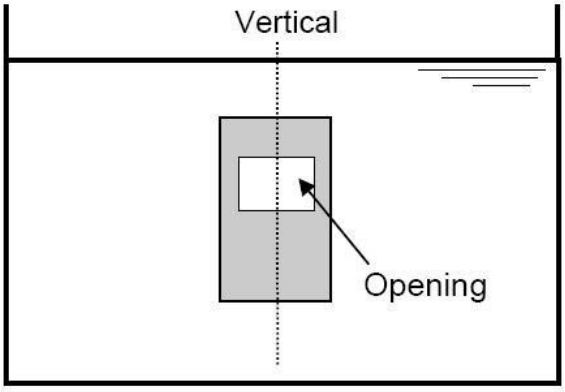

Figure 1 Example of normal position

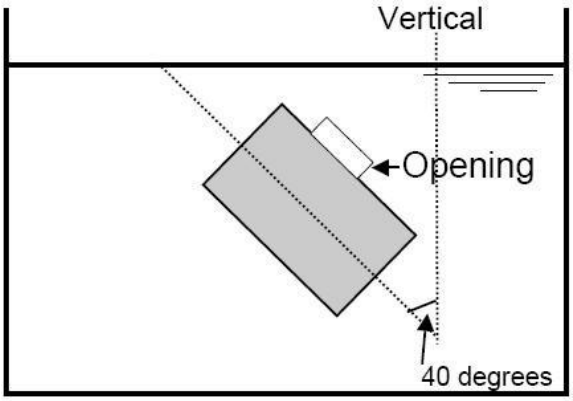

Figure 2 Example of inclination 40 degrees opening facing upward

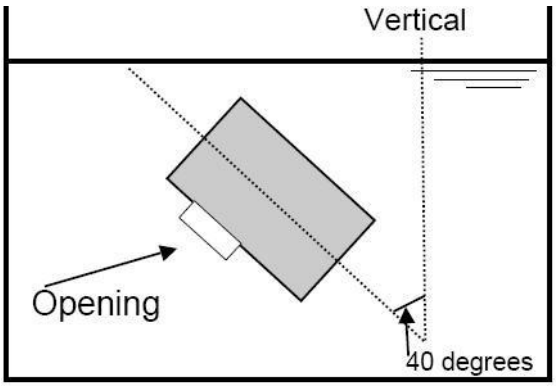

Figure 3 Example of inclination 40 degrees opening facing downward

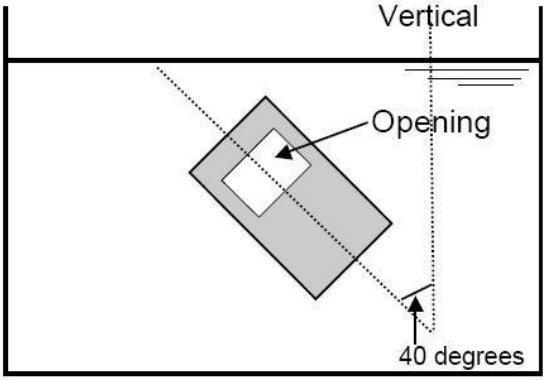

Figure 4 Example of inclination 40 degrees opening facing sideways

The maximum allowable leakage per cycle is not to exceed 2 ml/mm of nominal diameter of inlet pipe during any individual test.

(3) Discharge /reverse flow test

The air pipe head is to allow the passage of air to prevent excessive vacuum developing in the tank.

① Reverse flow test

a. A reverse flow is to be performed. A vacuum pump or another suitable device is to be connected to the opening of the air pipe leading to the tank. The flow velocity is to be applied gradually at a constant rate until the float gets sucked and blocks the flow.

b. The velocity at the point of blocking is to be recorded. 80% of the value recorded is to be stated in the certificate.

② Alternative to the reverse flow test

a. For pipe heads of 400 mm nominal diameter and above, as an alternative to the reverse flow test, a numerical simulation test based on computational fluid dynamics (CFD), to be carried out in conjunction with limited representative testing to establish the validity of the CFD modelling and results, may be accepted;

b. CFD predictions for air pipe heads can be validated against the available actual reverse flow test results of same size and type of air pipe heads;

c. The accuracy of the CFD modelling and the major assumptions used for the calculation are to be documented;

d. Mesh convergence studies are to be carried out and documented; and

e. The requirement as per the preceding ①b applies.

1.4.2 Testing of non-metallic floats

Impact and compression loading tests are to be carried out on the floats before and after pre-conditioning as shown in Table 1.4.2.

Pre-conditioning of test *Table 1.4.2*

Test condition \ Test temperature (℃)	-25	20	85
Dry	×	×	×
After immerging in water	×	×	×
After immerging in fuel oil	–	×	–
Immerging in water and fuel oil is to be for at least 48 h			

Abbreviations: × test is required
– test is not required

(1) Impact test

The test may be conducted on a pendulum type testing machine. The floats are to be subjected to 5 impacts of 2.5 Nm each and are not to suffer permanent deformation, cracking or surface deterioration at this impact loading.

Subsequently the floats are to be subjected to 5 impacts of 25 Nm each. At this impact energy level some localized surface damage at the impact point may occur. No permanent deformation or cracking of the floats is to appear.

(2) Compression loading test

Compression tests are to be conducted with the floats mounted on a supporting ring of a diameter and bearing area corresponding to those of the float seating with which it is intended that float is to be used.

For ball type float, loads are to be applied through a concave cap of the same internal radius as the test float and bearing on an area of the same diameter as the seating.
For a disc type float, loads are to be applied through a disc of equal diameter as the float.
A load of 350 kg is to be applied over one minute and maintained for 60 min. The deflection is to be measured at intervals of 10 min after attachment of the full load. The record of deflection against time is to show no continuing increase in deflection and, after release of the load, there is to be no permanent deflection.

1.4.3 Testing of metallic floats

Tests are to be conducted in accordance with 1.4.2(1). The tests are to be carried out at room temperature and in the dry condition.

CHAPTER 3 SHIP'S PIPING AND VENTILATING SYSTEMS

Section 1 GENERAL PROVISIONS

3.1.1 *Application*

3.1.1.1 The requirements of this Chapter apply to piping and ventilating systems on ships except where otherwise stated.

3.1.2 *Materials*

3.1.2.1 Except where otherwise stated in this Chapter, pipes, valves and fittings are to be made of steel, cast iron, copper, copper alloy, or other approved material suitable for the intended service.

3.1.2.2 Materials sensitive to heat, such as aluminum, lead or plastics, are not to be used in systems essential to the safe operation of the ship, or in systems conveying combustible liquids or sea water where leakage or failure could result in fire or in flooding of watertight compartments. For the use of plastic pipes, see Section 4 of Chapter 2 of this PART.

3.1.3 *Plans and documents*

3.1.3.1 The plans and documents to be submitted as required in this Chapter are referred to in 2.1.2 of this PART.

Section 2 DRAINAGE OF COMPARTMENTS, OTHER THAN MACHINERY SPACES

3.2.1 *General requirements*

3.2.1.1 All ships are to be provided with efficient bilge pumping systems capable of pumping from and draining any watertight compartment, other than a space permanently appropriated for the carriage of fresh water, water ballast, oil fuel or liquid cargo, and any other space where efficient means of pumping are available under all practical conditions. For particular compartments, if the survival capability and the safety of the ship are not impaired by flooding of the compartments, bilge pumping arrangements may be dispensed with.

Efficient means are to be provided for draining water from insulated holds. For their particular requirements, see relevant provisions specified in Chapter 3 of PART FIVE of the Rules.

3.2.1.2 The suctions and means for drainage are to be so arranged that any water within any compartment of the ship, or any watertight section of any compartment, can be pumped out through at least one suction when the ship is on an even keel and is either upright or has a list of not more than 5°. For this purpose, wing suctions will generally be necessary, except in short, narrow compartments where one suction can provide effective drainage under the above conditions.

3.2.1.3 In passenger ships, the bilge pumping plant is to be capable of draining any one watertight compartment which is neither a permanent oil compartment nor a permanent water compartment under all practicable conditions after a casualty, whether the ship is upright or listed.

3.2.2 *Cargo holds*

3.2.2.1 The bilge suctions in cargo holds are to be arranged in accordance with Table 3.2.2.1.

Bilge suction arrangements in cargo holds *Table 3.2.2.1*

Cargo holds condition		Suction arrangement in each cargo hold
Without double bottom	Bottom shell slopping down to the center line ≥ 5°	One near center line at after end
	Bottom shell slopping down to the center line < 5°	One on each side at after end
With double bottom	Inner bottom plating extending to ship's side and forming bilges at the wings	One on each side

Cargo holds condition		Suction arrangement in each cargo hold
	Inner bottom slopping down to the center line	One near center line
	Inner bottom plating extending to ship's side and not forming bilge	One bilge well with suction on each side
In ships having only one hold, and the length of the hold exceeds 35 m		Fitted in forward half-length and after half-length of the hold
In narrow holds at the ends of ships		One near center line

3.2.2.2 Enclosed cargo spaces situated on the bulkhead deck of a passenger ship and on the freeboard deck of a cargo ship

Drainage arrangement of enclosed cargo spaces situated on the bulkhead deck of a passenger ship and on the freeboard deck of a cargo ship may discharge in the form of gravity drainage by means of scupper according to the following requirements:

(1) Where the freeboard to the bulkhead deck or the freeboard deck, respectively, is such that the deck edge is immersed when the ship heels more than 5°, the drainage is to be by means of a sufficient number of scuppers of suitable size discharging directly overboard.

The arrangement of such scupper pipes is to be in accordance with the requirements of regulation 22, Annex I to Annex B of the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

(2) Where the freeboard is such that the edge of the bulkhead deck or the edge of the freeboard deck, respectively, is immersed when the ship heels 5° or less, the drainage of the enclosed cargo spaces on the bulkhead deck or on the freeboard deck, respectively, is to be led to a suitable space, or spaces, of adequate capacity, having a high water level alarm and provided with suitable arrangements for discharge overboard.

(3) Scuppers are to be provided at both port and starboard. The number and disposition of the scuppers are such as to prevent unreasonable accumulation of free water. Grills are to be provided at the open end of the scupper and the scuppers are not to be less than 100 mm in diameter.

(4) Where the enclosed cargo space is protected by a fixed pressure water-spraying fire-extinguishing system, the pumping arrangements are to take into account the requirements for any fixed pressure water-spraying fire-extinguishing system.

(5) Where the enclosed cargo space is protected by a carbon dioxide free-extinguishing system, the deck scuppers are fitted with means to prevent the escape of the smothering gas.

(6) Water contaminated with petrol or other dangerous substances is not drained to machinery spaces or other spaces where sources of ignition may be present.

3.2.3 *Holds and deep tanks for alternative carriage of liquid or dry cargo*

3.2.3.1 Where the inner bottom is slopping down to the centre line with an angle of not less than 5°, one centre suction only will be accepted and the wing suctions may be omitted.

3.2.3.2 In holds and deep tanks for alternative carriage of liquid or dry cargo, the liquid cargo and water ballast filling and suction pipes are to be provided with blanking flanges or other equivalent means, also the bilge suction pipes are to be provided with blanking flanges in way of the bulkheads, so as to isolate the filling and suction pipes when the hold or tank is being used for the carriage of dry cargo, and to isolate the bilge suction pipes when the hold or tank is being used for the carriage of liquid cargo or water ballast.

3.2.4 *Fore peaks, after peaks and cofferdams*

3.2.4.1 Where the peaks are used as dry compartments, the drainage of both peaks is to be effected either by a power pump branch bilge suction or a hand pump suction. In the latter case, the suction lift is in no case to exceed 7 m.

3.2.4.2 Suitable drainage arrangements are to be provided in cofferdams.

3.2.5 *Spaces above fore peaks, after peaks and machinery spaces*

3.2.5.1 The chain locker and the watertight compartments above the fore peak tank are to be drained by hand pump or power pump bilge suctions. Other effective means of drainage are also acceptable.

3.2.5.2 Steering gear compartments or other small enclosed spaces situated above the after peak tank are to be drained either by hand pump or power pump bilge suctions. Such compartments may also be drained by scuppers of not less than 38 mm bore, discharging to the shaft tunnels (or machinery space in the case of ships with machinery aft) and fitted with self-closing cocks or shut-off valves situated in well lighted and easily visible positions.

3.2.6 *Shaft tunnel and pipe tunnel*

3.2.6.1 The shaft or pipe tunnel is, in general, to be drained by a branch bilge suction at the after end of

the tunnel. Where water might accumulate at the forward end of the tunnel or the length of the tunnel is more than 35 m, additional bilge suction is required.

Section 3 BILGE DRAINAGE OF MACHINERY SPACES

3.3.1 *General requirements*

3.3.1.1 The bilge drainage arrangements in the machinery space are to be such that any water which may enter this compartment can be pumped out through at least two bilge suctions when the ship is on an even keel, and is either upright or has a list of not more than 5°. One of these suctions is to be branch bilge suction, and the other is to be direct bilge suction.

3.3.1.2 In passenger ships, the drainage arrangements are to be such that machinery spaces can be pumped out under all practical conditions after a casualty, whether the ship is upright or listed.

3.3.2 *Bilge suction arrangements in machinery spaces*

3.3.2.1 The bilge suctions in machinery spaces are to be arranged in accordance with Table 3.3.2.1.

Bilge suction arrangements in machinery spaces *Table 3.3.2.1*

Condition of machinery spaces		Branch bilge suction	Direct bilge suction
Main engine room with single bottom	Bottom shell slopping down to the center line ≥ 5°	One near center line	One near center
	Bottom shell slopping down to the center line < 5° and all passenger ships	One near center line and one on each side	One near center
Main engine room with double bottom	Inner bottom extends the full length of the machinery space and forms bilges at the wings	One on each side	One on each side
	Inner bottom extends the full length and breadth of the machinery space	One bilge well with one suction on each side	One bilge well with one suction on each side
Ships with propelling machinery aft		One on each side at the fore end and one at central longitudinal plane at aft end	One on each side at the fore end of engine room
Boiler room or auxiliary engine room separated from the main engine room by watertight bulkheads; separate motor room of electrically propelled ships		Same as for cargo holds	At least one for each watertight compartment

3.3.2.2 Additional bilge suctions may be required for the drainage of depressions in the tank top formed by crank-pits, or other recesses, by tank tops having inverse camber or by discontinuity of the double bottom.

3.3.2.3 In ships propelled by electrical machinery, in addition to the branch bilge suctions and direct bilge suctions arranged appropriate to the conditions of machinery space, special means are to be provided to prevent the accumulation of bilge water under the main propulsion generators and motors.

3.3.2.4 In passenger ships, each independent bilge pump is to have a direct bilge suction from the space in which it is situated, but not more than two such suctions are required in any one space. Where two or more such suctions are provided, there is to be at least one suction on each side of the space.

3.3.3 *Emergency bilge suctions of machinery spaces*

3.3.3.1 In addition to the bilge suctions required in 3.3.2.1 to 3.3.2.4 of this Section, an emergency bilge suction is to be provided in each main machinery space. This suction is to be led to a main cooling water pump and is to be fitted with a screw-down non-return valve having the spindle so extended that the hand wheel is 450 mm above the bottom platform.

3.3.3.2 In ships with steam propelling machinery, the emergency suction is to have a diameter of at least 2/3 that of the main circulating pump suction. In other ships, the diameter of suction is not to be less than the diameter of the pump suction.

3.3.3.3 Where main cooling water pumps are not suitable for bilge pumping duties, the emergency bilge suction is to be led to the largest power pump which is not a bilge pump. This pump is to have a capacity not less than that required for a bilge pump, and the bilge suction is at least to be the same size as that of the pump suction branch.

Where the pump to which the emergency bilge suction is connected is of the self-priming type, the direct bilge suction on the same side of the ship may be omitted, except in passenger ships.

3.3.3.4 Emergency bilge suction valves are to be provided with permanent nameplates clearly indicating

their purpose.

Section 4 BILGE PUMPS AND BILGE PIPING

3.4.1 *Number of bilge pumps*

3.4.1.1 The number of power bilge pumps for each ship is to comply with the requirements of Table 3.4.1.1.

Number of power bilge pumps *Table 3.4.1.1*

Ship type, navigation area and parameters			Independent power pump	Power pump driven by main engine or independent power pump
Passenger ship	Passenger ships engaged on international voyages; Passenger ships with service category 1 and upper than category 1; Passenger ships carrying more than 500 passengers with service category 2;	Bilge pump numeral ≥ 30	3	1
		Bilge pump numeral < 30	2	1
	Passenger ships other than those listed above		2	1
Ships other than passenger ship		Ship's length > 91.5m	2	–
		Ship's length ≤ 91.5m	1	1

3.4.1.2 Each bilge pump prescribed in 3.4.1.1 of this Section may be substituted by a pumping unit consisting of several pumps. The total capacity of each pumping unit is not to be less than the capacity of a bilge pump specified in 3.4.2.4 of this Section.

3.4.1.3 Independent power sanitary, ballast and general service pumps may be accepted as independent power bilge pumps, provided they are of the required capacity of the self-priming type or with the self-priming arrangement and connected to the bilge main.

3.4.1.4 For ships other than passenger ships, an ejector with an adequate pressure of water supply from a sea water pump and connected to the bilge piping may be accepted as an independent power bilge pump.

3.4.1.5 For passenger ships, the bilge pump numeral C is to be calculated as follows:

when P_1 is greater than P: $C = \frac{72(M + 2P_1)}{V + P_1 - P}$

in other cases: $C = \frac{72(M + 2P)}{V}$

where:

M — the volume of the machinery space, in m^3, as defined in SOLAS regulation II-1/2, that is below the bulkhead deck; with the addition thereto of the volume of any permanent oil fuel bunkers which may be situated above the inner bottom and forward of, or abaft, the machinery space;

V— the whole volume of the ship below the bulkhead deck, in m^3;

P— the whole volume of the passenger and crew spaces below the bulkhead deck, in m^3, which are provided for the accommodation and use of passengers and crew, excluding baggage, store, provision and mail rooms;

$$P_1 = KN$$

where:

N — the number of passengers for which the ship is to be certified; and

$K = 0.056L$

where:

L — the length of the ship, in m, as defined in SOLAS regulation II-1/2.

However, where the value of KN is greater than the sum of P and the whole volume of the actual passenger spaces above the bulkhead deck, the figure to be taken as P_1 is that sum or two-thirds KN, whichever is the greater.

3.4.2 *Type and capacity of bilge pumps*

3.4.2.1 All power bilge pumps are to be of the self-priming type, or with the self-priming arrangements.

3.4.2.2 Cooling water pumps having emergency bilge suctions need not be of the self-priming type, or with self-priming arrangements.
3.4.2.3 Each power bilge pump is to be capable of giving a speed of water through the required main bilge pipe of not less than 2 m per second.
3.4.2.4 The capacity of each bilge pump (Q) is not to be less than the value calculated by the following formula:

$$Q = 5.66\, d_1^2 \times 10^{-3} \quad \text{m}^3/\text{h}$$

where: d_1 — internal diameter of bilge main, obtained from the formula in 3.4.3.1 of this Section, in mm.
3.4.2.5 In ships other than passenger ships, where one bilge pump is of slightly less than the rule capacity, the deficiency may be made good by an excess capacity of the other pumps. In general, this deficiency is to be limited to 30%.

3.4.3 *Bilge pipe systems*

3.4.3.1 The internal diameter d_1 of the bilge main is to be calculated according the following formula. However, the actual internal diameter of the bilge main may be rounded off to the acceptable nearest standard size, but not less than the calculated value by 5 mm:

$$d_1 = 25 + 1.68\sqrt{L(B + D)} \quad \text{mm}$$

where: L — length of ship, in m (measured between perpendiculars taken at the extremities of the deepest subdivision load line).
Where the engine room bilge pumps are fitted primarily for serving the engine room and they do not serve cargo space bilges, L may be reduced by the combined length of the cargo tanks or cargo holds. In such cases, the cross sectional area of the main bilge line is not to be less than twice the required cross sectional area of the engine room branch bilge lines;
B — breadth of ship, in m (the extreme width from outside of frame to outside of frame at or below the deepest subdivision load line).
D — molded depth of ship to bulkhead deck, in m.
When the bilge of enclosed cargo spaces situated on the bulkhead deck or freeboard deck is drained by means of bilge system, D is to be selected according to following requirements:
(1) when the enclosed cargo space extends for the full length of the ship, D is to be measured to the next deck above the bulkhead deck;
(2) where the enclosed cargo spaces cover a lesser length, D is to be taken as the molded depth to the bulkhead deck plus lh/L, where l and h are the aggregate length and height respectively of the enclosed cargo spaces.

3.4.3.2 In no case is the internal diameter of the bilge main to be less than that required for the largest branch bilge line.
3.4.3.3 The internal diameter d_2 of branch bilge suction pipes fitted in cargo and machinery spaces is not to be less than the value determined by the following formula, but the actual internal diameter of branch bilge suction pipes may be rounded off to the acceptable nearest standard size, but not less than the calculated value by 5 mm:

$$d_2 = 25 + 2.15\sqrt{l(B + D)} \quad \text{mm}$$

where: l — length of compartment, in m;
B— breadth of ship, in m;
D— molded depth of ship to bulkhead deck, in m.
3.4.3.4 In general, no branch bilge suction pipe is to be less than 50 mm bore.
3.4.3.5 In no case is the internal diameter of the direct bilge suction to be less than that required for the main bilge line.
3.4.3.6 The branch bilge suction pipe to the tunnel well is, in general, not to be less than 65 mm bore.
3.4.3.7 The section area of each branch pipe connecting the bilge main to a distribution chest is not to be less than the sum of the areas required for the two largest branch bilge suction pipes connected to that chest, but need not be greater than that required for the main bilge line.

3.4.4 *Bilge pumps and pipe connections*

3.4.4.1 The connections at the bilge pumps are to be such that at least one of the pumps may continue in operation when the other pumps are being opened up for overhaul.
3.4.4.2 The arrangements of pump and pipelines are such that the working of any of the pumps so

connected is unaffected by the other pumps being in operation at the same time.
3.4.4.3 All bilge suction pipes are to be independent of other piping up to the bilge pump suction valve chest.

3.4.5 *Non-return arrangements*
3.4.5.1 For the purpose of preventing the possibility of one watertight compartment being placed in communication with another, or of dry cargo spaces, machinery spaces or other dry compartments being placed in communication with the sea or with tanks, screw-down non-return valves are to be provided in the following fittings:
(1) bilge valve distribution chests;
(2) bilge suction hose connection, whether fitted direct to the bilge pump or on the main bilge line;
(3) direct bilge suctions;
(4) bilge pump connections to main bilge line.

3.4.6 *Blanking arrangements*
3.4.6.1 In the case of deep tanks and cargo holds which may be used for either water ballast or dry cargo, provision is to be made for blank flanging the water ballast filling and suction pipes when the tank or hold is being used for the carriage of dry cargo, and for blank flanging the bilge suction pipes when the tank or hold is being used for the carriage of water ballast.
For arrangement when oil fuel or cargo oil (having a flash point above 60°C) is carried in deep tanks, see 4.2.9.1 of this PART.

3.4.7 *Bilge pipes in way of deep tanks and double bottom tanks*
3.4.7.1 In way of deep tanks, bilge pipes are preferably to be led through pipe tunnels but, where this is not done, the pipes are to have a wall thickness in accordance with Table 2.2.2.6(1) of this PART, with welded joints or other reliable joints. The number of joints is to be kept to a minimum.
3.4.7.2 Expansion bends, not glands, are to be fitted to these pipes within the deep tanks, and the open ends of the bilge suction pipes in the holds are to be fitted with non-return valves of the approved type.
3.4.7.3 Bilge suction pipes are not to be led through double bottom tanks as far as practicable. Bilge pipes which have to pass through these tanks are to have a wall thickness in accordance with Table 2.2.2.6(1) of this PART.
3.4.7.4 Expansion bends, not glands, are to be fitted to these pipes within the double bottom tanks.
3.4.7.5 The pipes are to be tested after installation, to a pressure not less than that required for the deep or double bottom tanks through which they pass.

3.4.8 *Bilge fittings*
3.4.8.1 Where the inner bottom plating in machinery spaces or cargo holds extends to the ship's side and does not form bilges, the bilge suctions are to be arranged in bilge wells. The bilge wells are to be formed of steel plates and are not to be less than 0.15 m^3 in capacity.
3.4.8.2 Each branch bilge suction and each direct bilge suction in machinery spaces and tunnels (excluding emergency suctions) are to be led from easily accessible mud boxes fitted with straight tail pipes to the wells or bilges. Strum boxes are not to be fitted to the lower ends of these tail pipes or to the emergency bilge suctions.
3.4.8.3 The open ends of bilge suctions in holds and other compartments outside machinery spaces and tunnels are to be enclosed in strum boxes having perforations of not more than 10 mm diameter, whose combined area is not less than twice that required for the suction pipe. The strum boxes are to be so constructed that they can be easily removed and replaced for cleaning.
3.4.8.4 Bilge valves, cocks and mud boxes are as far as possible to be fitted at, or above, the machinery space and tunnel platforms. Where they are situated just below the platform, provided readily removable traps or covers are to be fitted, and nameplates are to be fitted to indicate the presence of these fittings.

3.4.9 *Miscellaneous*
3.4.9.1 The design, construction and arrangement of sludge tanks and standard discharge connections are to comply with the provisions of relevant international conventions.
3.4.9.2 Bilge piping systems are to be so arranged as to meet the relevant requirements for the prevention of pollution from ships.

Section 5 ADDITIONAL REQUIREMENTS FOR BILGE DRAINAGE FOR PASSENGER SHIPS

3.5.1 *Arrangement of bilge pumps and bilge main*

3.5.1.1 In passenger ships the required power bilge pumps are to be placed, if practicable, in separate watertight compartments. If the engines and boilers are in two or more watertight compartments, the bilge pumps are to be distributed throughout these compartments so far as is possible.

3.5.1.2 In passenger ships of 91.5 m or more in length, or having a bilge pump numeral of 30 or more, the arrangements are to be such that at least one of the power bilge pumps will be available for use in all ordinary circumstances in which the ship may be flooded at sea. This requirement will be satisfied if:

(1) one of the pumps is a reliable emergency pump of a submersible type having its source of power situated above the bulkhead deck;

(2) the pumps and their sources of power are so disposed throughout the length of the ship that, under any conditions of flooding which the ship is required to withstand, at least one pump in an undamaged compartment will be available.

3.5.1.3 The bilge main is to be so arranged that no part is situated nearer the side of the ship than *B*/5 (*B* being the breadth of ship), measured at right angles to the centreline at the level of the deepest subdivision load line.

3.5.1.4 Where any bilge pump or its pipe connection to the bilge main is situated outboard of the *B*/5 line, then a non-return valve is to be provided in the pipe connection at the junction with the bilge main. The emergency bilge pump and its connections to the bilge main are to be so arranged that they are situated inboard of the *B*/5 line.

3.5.2 *Arrangement of bilge pipes*

3.5.2.1 Provision is to be made to prevent the compartment served by any bilge suction pipe being flooded in the event of the pipe being severed, or otherwise damaged by collision or grounding in any other compartment. For this purpose, where the pipe is at any part situated nearer the side of the ship than *B*/5 or in a duct keel, a non-return valve is to be fitted to the pipe in the compartment containing the open end.

3.5.2.2 All the distribution boxes, valves and cocks in connection with the bilge pumping arrangements are to be in positions which are accessible at all times under ordinary circumstances. They are to be so arranged that, in the event of flooding, one of the bilge pumps may be operative on any compartment. In addition, damage to a pump or its pipe connecting to the bilge main situated outboard of *B*/5 line is not to put the bilge system out of action. If there is only one system of pipes common to all the pumps, the necessary cocks or valves for controlling the bilge suctions must be capable of being operated from above the bulkhead deck. Where in addition to the main bilge pumping system an emergency bilge pumping system is provided, it is to be independent of the main system, and so arranged that a pump is capable of operating on any compartment under flooding conditions. In this case only the cocks and valves necessary for the operation of the emergency system need be capable of being operated from above the bulkhead deck.

3.5.2.3 All cocks and valves mentioned in 3.5.2.2 of this Chapter which can be operated from above the bulkhead deck are to have their controls at their place of operation clearly marked and provided with means to indicate whether they are open or closed.

Section 6 ADDITIONAL REQUIREMENTS FOR BILGE DRAINAGE

3.6.1 *Additional requirements for bilge drainage for oil tankers*

3.6.1.1 For the additional requirements for bilge drainage for oil tankers, see relevant provisions of Section 3, Chapter 5 of this PART.

3.6.2 Additional requirements for bilge drainage for spaces using fixed pressure water-spraying fire-extinguishing systems①

3.6.2.1 Pumping and drainage facilities are to be provided in spaces using fixed pressure water-spraying fire-extinguishing systems for draining large quantities of water accumulation on the deck or tank top on consequence of the operation of the fixed pressure water-spraying system, and following requirements are

① Refer to MSC.1/Circ.1320: Guidelines for the Drainage of Fire-fighting Water from Closed Vehicle and Ro-Ro Spaces and Special Category Spaces of Passenger and Cargo Ships.

to be complied with.

(1) For passenger ships:

① In the spaces above the bulkhead deck, scuppers complying with relevant requirements of MSC.1/Circ.1320 are to be fitted so as to ensure that such water is rapidly discharged overboard. Discharge valves for scuppers, fitted with positive means of closing operable from a position above the bulkhead deck in accordance with the requirements of regulation 22, Annex I to Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966, are to be kept open while the ships are at sea.

② In the spaces below the bulkhead deck, pumping and drainage facilities complying with relevant requirements of MSC.1/Circ.1320 may be required to be provided additional to the requirements of Section 2 to Section 5 of this Chapter. The drainage system valves are to be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells are to be of sufficient holding capacity and are to be arranged at the side shell of the ship at a distance from each other of not more than 40 m in each watertight compartment.

(2) For cargo ships:

The drainage and pumping arrangements are to be such as to prevent the build-up of free surfaces and comply with relevant requirements of MSC.1/Circ.1320. The drainage system valves are to be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells are to be of sufficient holding capacity and are to be arranged at the side shell of the ship at a distance from each other of not more than 40 m in each watertight compartment.

If this is not possible, the adverse effect upon stability of the added weight and free surface of water is to be taken into account in its approval of the stability information. Such information is to be included in the stability information supplied to the master as required.

3.6.2.2 On all ships, for closed vehicles and ro-ro spaces and special category spaces, where fixed pressure water-spraying systems are fitted, means are to be provided to prevent the blockage of drainage arrangements and relevant requirements of MSC.1/Circ.1320 are to be complied with.

3.6.3 *Additional requirements for bilge drainage for periodically unattended machinery spaces*

3.6.3.1 For the additional requirements of bilge drainage for periodically unattended machinery spaces, see relevant provisions of 3.9.2 of Chapter 3 in PART SEVEN of the Rules.

3.6.4 *Additional requirements for bilge drainage for unattended other machinery spaces*

3.6.4.1 Bilge level alarms are to be provided for unattended other machinery spaces below waterline (e.g. athwartship thruster space, emergency fire pump space, etc.).

Section 7 DRAINAGE ARRANGEMENTS AND BALLAST PIPING FOR NON-SELF-PROPELLED SHIPS

3.7.1 *General requirements*

3.7.1.1 Non-self-propelled ships are to be provided with means for drainage of all watertight compartments which give contribution to the vessel's buoyancy and floatability (except for compartments permanently used to carry liquid).

3.7.1.2 This Section is the additional requirements to drainage arrangements and ballast piping for non-self-propelled ships. With the exemption specified in the following, the rules and principles for drainage of ship with propulsion machinery are to be referred to.

3.7.2 *Pierhead pontoon and non-self-propelled ships without auxiliary power*

3.7.2.1 For pierhead pontoon and non-self-propelled ships without auxiliary power, at least two portable hand pumps are to be fitted to permit the efficient drainage of each compartment. Suitable access hatches for the pumping equipment are to be provided for each compartment.

3.7.2.2 The internal diameter d of the hand pump suction is not to be less than the value determined by the following formula:

$$d = 0.01T + 50 \quad \text{mm}$$

where: T — tonnage under upper deck, in t.

Where the ship is subdivided into small watertight compartments, 50 mm bore suction will be accepted. The internal diameter of the water cylinder of piston pumps is not to be less than twice the required diameter of the suction.

3.7.3 *Manned non-self-propelled ships with auxiliary power*

3.7.3.1 In non-self-propelled ships with auxiliary power, permanently installed bilge system with power bilge pumps are to be provided for dealing with the drainage of tanks and principal compartments.

3.7.3.2 Manned ships with auxiliary power for unlimited service are to be equipped with two power driven bilge pumps.

3.7.3.3 Manned ships with auxiliary power for limited service may have one power driven bilge pump, but in this case, the bilge pump is not to serve as fire pump.

3.7.3.4 All compartments required to be equipped with bilge drainage arrangements are to have branch bilge suction connected with bilge system.

3.7.3.5 In addition to branch bilge suction, a direct bilge suction to bilge pump is to be provided for the engine room.

3.7.3.6 Dry compartments in fore and aft peak may be drained by hand pumps.

3.7.3.7 Rooms situated on deck may be drained directly overboard.

3.7.4 *Unmanned non-self-propelled ships with auxiliary power*

3.7.4.1 Unmanned ships with auxiliary power are to be provided with a power driven bilge pump.

3.7.4.2 Any engine room or pump room is to have bilge suctions to power bilge pump.

3.7.4.3 Other compartments may be drained by portable pumps. Suitable access hatches for the pumping equipment are to be provided for each compartment.

3.7.5 *Ballast system of non-self-propelled ships*

3.7.5.1 For non-self-propelled ships fitted with ballast tank, each ballast tank is to be provided with ballast system connected by pipes.

3.7.5.2 Pierhead pontoon and non-self-propelled ships without auxiliary power may permit to use a portable pump as ballast pump.

3.7.5.3 Non-self-propelled ships with auxiliary power are to be provided with at least one power driven ballast pump.

Section 8 BALLAST AND SCUPPER SYSTEMS

3.8.1 *Ballast piping*

3.8.1.1 The arrangement of ballast piping and the number of suctions are to be such that any ballast tank can be filled or emptied under normal service conditions, whether the ship is upright or listed.

3.8.1.2 Where the ballast tanks exceed 35 m in length, they are normally to be fitted with bilge suctions at their forward and aft ends.

3.8.1.3 The arrangement of ballast piping is to be such as to prevent the possibility of water passing from the sea or from ballast tanks into dry cargo and machinery spaces or other dry compartments.

3.8.1.4 Ballast water pipes are not to pass through drinking water, boiler feed water or lubricating oil tanks. Where it is unavoidable, the wall thickness of ballast pipes in drinking water, feed water or lubricating oil tanks is to comply with the provisions of column 5 in Table 2.2.2.6(1) of this PART and welded joints are to be adopted. Ballast water pipes passing through a pipe tunnel may also be an option.

3.8.1.5 The ballast piping is not to be in connection with the bilge pipes from dry cargo and machinery spaces, nor with the pipes from oil tanks. However, this requirement need not be applied to the pipes located between distribution boxes and pump suctions or between pumps and overboard discharges, nor to the pipes described in 3.8.1.6 below.

3.8.1.6 Where the compartments (including deep tanks) are used for alternative carriage of dry cargo or oil or ballast water, provision is to be made for isolating or blank flanging the ballast lines. This requirement is also applicable to the drinking water tanks which may be used as ballast tanks, so as to avoid the interconnection of the two systems. The arrangement for the discharge of oily ballast water is to be in accordance with the relevant requirements for the prevention of pollution from ships.

3.8.1.7 Alternate loading of fuel oil and ballast water is to comply with the relevant requirements of 4.2.9, Chapter 4 of this PART.

3.8.1.8 For the requirements of ballast system in oil tankers, see the relevant provisions in Section 3, Chapter 5 of this PART.

3.8.2 *Scuppers and sanitary discharges*

3.8.2.1 For the requirements of scuppers and sanitary discharges, see the relevant requirements specified

in regulation 22, Annex I to Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

3.8.2.2 The installation of all suction and discharge valves or side standpipes on scuppers and sanitary discharges that are secured direct to the shell plating of the ship is to be in compliance with the relevant requirements of 2.8.9.2 of this PART.

Section 9 REMOTELY CONTROLLED BILGE AND BALLAST SYSTEMS

3.9.1 *Arrangement*

3.9.1.1 If a main bilge line outside engine room is provided, its arrangement is to satisfy either of the following requirements:

(1) If there is only one main bilge line and a pipe tunnel is provided, it is to be placed in the pipe tunnel, and as high as possible in the pipe tunnel. Each branch bilge suction line connected to the main is to be fitted with remotely controlled valves.

(2) If there is only one main bilge line and a pipe tunnel is not provided, the main is to be placed in a space that is not prone to mechanical damage, such as double bottom ballast tanks and void tanks, etc. Each branch bilge suction line connected to the main is to be fitted with remotely controlled valves and the valves are to be located in an accessible dry compartment.

(3) If there are two main bilge lines, each cargo hold is provided with a branch bilge suction connected to each main bilge line respectively, and remotely controlled valves are fitted on each branch bilge suction line.

3.9.1.2 The main bilge line for cargo holds is to be dimensioned as the machinery spaces main bilge line.

3.9.1.3 The main bilge line for cargo holds is to be fitted with a shut-off valve in the machinery spaces.

3.9.2 *Valves*

3.9.2.1 The remotely controlled valves in branch bilge suction lines are to be screw-down non-return valves or shut-off and non-return valves connected in series.

3.9.3 *Pumps*

3.9.3.1 Operating indications of the remotely controlled bilge and ballast pumps are to be provided at the remote control panel.

Section 10 AIR, OVERFLOW AND SOUNDING PIPES

3.10.1 *General requirements*

3.10.1.1 The cargo mentioned in this Section is the oils having a flash point above 60℃(closed cup test).

3.10.1.2 Air, overflow and sounding pipes are to be made of steel or other approved material.

3.10.1.3 Nameplates are to be affixed to the upper ends of all air and sounding pipes.

3.10.1.4 In addition to complying with the requirements of this Section, air pipes are to be in compliance with the relevant provisions in 1.12.7.5 of PART TWO of the Rules.

3.10.2 *Arrangement of air pipes*

3.10.2.1 Air pipes are to be provided for tanks intended to carry water, oil fuel and lubricating oil, and also for cofferdams and pipe tunnels. The shaft tunnel is to be provided with air pipes if necessary. Air pipes are to be fitted at the highest part of the tanks and far apart from the filling pipes.

3.10.2.2 Tanks having top plates not less than 7 m either in length or in width are to be provided with two or more air pipes arranged suitably apart. Where such arrangements are impracticable due to special circumstances, one air pipe is acceptable provided that effective venting is guaranteed. Where the tank top is of unusual or irregular profile, the number and positions of the air pipes will be decided in each case.

3.10.2.3 Tanks with cathodic protection are to have air pipes fitted forward and aft.

3.10.2.4 All double bottom tanks are to be fitted with air pipes. The double bottom tanks extending from side to side of the ship are to be fitted with air pipes led from both sides. For the double bottom tanks with less breadth at the ship's bow and stern, however, only one vent pipe may be fitted, provided that this single pipe can ensure the effective venting.

3.10.2.5 Location and arrangement of vent pipes for fuel oil service, settling and lubrication oil tanks are

to be such that in the event of a broken vent pipe this will not directly lead to the risk of ingress of seawater splashes or rainwater.
3.10.2.6 The arrangement of the air piping is to be such that in the event of any one of the tanks being damaged, tanks situated in other watertight compartments of the ship cannot be flooded from the sea through combined air pipes.

3.10.3 *Termination of air pipes*

3.10.3.1 Air pipes to the following tanks and cofferdams are to be led to the open above the freeboard deck:
(1) fuel oil tanks;
(2) cargo tanks;
(3) heated lubricating oil tanks and hydraulic oil tanks;
(4) tanks, situated outside machinery spaces, which are not fitted with overflow pipes and can be pumped up;
(5) cofferdams adjacent to fuel oil tanks or cargo tanks.
3.10.3.2 Air pipes to the following tanks and cofferdams other than those prescribed in 3.10.3.1 of this Section are to be led to above the bulkhead deck:
(1) double bottom tanks;
(2) deep tanks extending to shell plating;
(3) tanks which can be directly flooded from the outboard and seawater case;
(4) other cofferdams.
3.10.3.3 Air pipes from lubricating oil tanks or fuel oil draining tanks with a volume less than 0.5 m^3 and which cannot be pumped up may terminate in the machinery space, provided that the open ends are so situated that issuing oil cannot come into contact with electrical equipment or heated surfaces.
3.10.3.4 The open ends of air pipes to oil fuel and cargo tanks are to be situated on the open deck where no danger will be incurred from issuing oil or vapor.
3.10.3.5 The open ends of air pipes to oil fuel and cargo tanks are to be furnished with a wire gauze diaphragm of corrosion-resistant material which can be readily removed for renewal.
3.10.3.6 The wire gauze diaphragm at the open ends of air pipes is to have a clear area not less than the cross-sectional area required for the air pipe.

3.10.4 *Size of air pipes*

3.10.4.1 In the case of all tanks which can be pumped up, either by the ship's pumps or by shore pumps through a filling main, the total cross-sectional area of the air pipes to each tank is not to be less than 25% greater than the effective area of the respective filling pipes. In any case, the internal diameter of air pipes is not to be less than 50 mm. When an air pipe serves several tanks, the sectional area of the air pipe is to be at least the combined area of the largest air pipes for two tanks.
3.10.4.2 Where overflow pipes are fitted as specified in this Section, the sectional area of the air pipes is to be at least 20% of that of the filling pipes.
When an air pipe serves several tanks all having overflow pipes as specified in this Section, the sectional area of the air pipe is to be at least 20% of the combined area of the two largest filling pipes for the separate tanks.
3.10.4.3 For ships navigating in ice, the cross-sectional area of air pipes is to be adequately increased.
3.10.4.4 Where tanks form part of the structure of the ship, the wall thickness of air pipes is to comply with Table 2.2.2.6(1) of this PART.
3.10.4.5 Air pipes to shaft tunnels and pipe tunnels are to have an internal diameter not less than 75 mm.

3.10.5 *Arrangement of overflow pipes*

3.10.5.1 All tanks which can be pumped up are to be fitted with overflow pipes, when the liquid pressure head corresponding to the height of the air pipe is greater than that for which the tanks are suitable, or when the sectional area of the air pipe is less than that required in 3.10.4.1 of this Section. When an air pipe serves several tanks, the air pipe of one tank is not to be considered as the overflow pipe of another tank, except the shared overflow pipe connected to the overflow tank.
3.10.5.2 In the case of oil fuel and lubricating oil tanks, the overflow pipe is to be led to an overflow tank of adequate capacity or to a storage tank having a space reserved for overflow purposes.
Overflow pipes from tanks, other than oil fuel and lubricating oil tanks, are to be led to the open or to suitable overflow tanks.
3.10.5.3 A well illuminated sight glass is to be provided in the overflow pipe, and placed on the vertical pipes in readily visible positions, or alternatively, an alarm device is to be provided to give warning either

when the tanks are overflowing or when the oil reaches a predetermined level in the tanks.
3.10.5.4 Shut-off valves or cocks are not allowed to be fitted to the overflow pipes.

3.10.6 *Size of overflow pipes*
3.10.6.1 The sectional area of overflow pipe(s) from each tank is not to be less than 1.25 times that of the filling pipe(s). When an overflow pipe serves several tanks, the sectional area of the overflow pipe is to be at least the combined area of the largest overflow pipes for two tanks.

3.10.7 *Prevention of cross flow through the overflow pipes*
3.10.7.1 Where overflows from deep tanks which are used for the alternative carriage of fuel oil, cargo oil, water ballast, or dry cargo are connected to an overflow main of other tanks, arrangements are to be made to prevent the overflowing of liquid, gases, etc. from other tanks into the deep tank carrying dry cargo, as well as to prevent the overflowing of liquid into other tanks from the deep tank carrying the liquid.

3.10.7.2 The arrangement of the overflow system is to be such that in the event of any one of the tanks being bilged, tanks situated in other watertight compartments of the ship cannot be flooded from the sea through the overflow main.

3.10.8 *Sounding pipes*
3.10.8.1 Sounding pipes are to be provided for all tanks, cofferdams and pipe tunnels as well as the bilges or bilge wells which are not at all times readily accessible. All sounding pipes are to be led to positions above the bulkhead deck which are at all times accessible.
The sounding pipes are to be fitted as near the suctions as practicable.
3.10.8.2 Other sounding devices may be used in lieu of sounding pipes for sounding tanks. These devices are to be tested satisfactorily, after fitting on board.
3.10.8.3 All sounding pipes exposed to sea and weather are to be provided with permanently attached effective means of closing to prevent the free entry of water.
3.10.8.4 The bottom plating under open ended sounding pipes is to be protected by striking plates of adequate thickness and size.

3.10.9 *Short sounding pipes*
3.10.9.1 In machinery spaces and shaft tunnels where it is not practicable to extend the sounding pipes as mentioned in 3.10.8.1 of this Section, short sounding pipes extending to readily accessible positions above the platform may be fitted. The following requirements are to be complied with:
(1) Sounding pipes are to be easily accessible and are to be fitted with shut-off cocks or with screw caps attached to the pipes by chains.
(2) In passenger ships, short sounding pipes are permissible only for sounding cofferdams and double bottom tanks situated in the machinery space, and are in all cases to be fitted with self-closing devices.

3.10.10 *Additional requirements to sounding pipes in fuel oil tanks*
3.10.10.1 Safe and efficient means of ascertaining the amount of oil fuel contained in any fuel oil tank are to be provided. Where sounding pipes are used, they are not to terminate in any space where the risk of ignition of spillage from the sounding pipe might rise. In particular, they are not to terminate in passenger or crew spaces. As a general rule, they are not to terminate in machinery spaces. However, where it is impracticable to arrange, termination of sounding pipes in machinery spaces may be permitted on condition that the following requirements are met:
(1) an oil-level gauge is provided meeting the requirements of 3.10.10.3 of this Section;
(2) the sounding pipes terminate in locations remote from ignition hazards unless precautions are taken, such as the fitting of effective screens, to prevent the oil fuel in the case of spillage through the terminations of the sounding pipes from coming into contact with a source of ignition;
(3) the termination of sounding pipes are fitted with self-closing blanking devices and with a small-diameter self-closing control cock located below the blanking device for the purpose of ascertaining before the blanking device is opened that oil fuel is not present. Provisions are to be made so as to ensure that any spillage of oil fuel through the control cock involves no ignition hazard.
3.10.10.2 For fuel oil tanks other than double bottom tanks, if overflow pipes satisfying requirements are fitted, when the sounding pipes are terminated in machinery spaces, only above-mentioned requirements of 3.10.10.1(2) and (3) are to be met.
3.10.10.3 Other oil-level gauges may be used in place of sounding pipes subject to the following conditions:

(1) in passenger ships, such gauges are not to require penetration below the top of the tank and their failure or overfilling of the tanks is not to permit release of fuel;
(2) in cargo ships, the failure of such gauges or overfilling of the tank is not to permit release of fuel into the space. The use of oil-level gauges with flat glasses and self-closing valves between the gauges and fuel tanks is permitted. The use of cylindrical gauge glasses is prohibited.

3.10.11 *Additional requirements to sounding pipes in lubricating oil tanks*

3.10.11.1 In general, means of ascertaining the amount of lubricating oil contained in any lubricating oil tank are to comply with the requirements of 3.10.10 of this Section. However, the requirements of 3.10.10.1(1) and 3.10.10.1(3) need not be applied on condition that the sounding pipes terminating in machinery spaces are fitted with appropriate means of closure.

3.10.12 *Additional requirements to sounding pipes in other flammable oil tanks*

3.10.12.1 For flammable oil tanks in spaces where means of ignition are present, means of ascertaining the amount of flammable oil contained in any flammable oil tank are to comply with the requirements of 3.10.10 of this Section.

3.10.12.2 For flammable oil tanks in other locations, if oil-level gauges are used in place of sounding pipes, at least the requirements of 3.10.10.3(2) are to be complied with.

3.10.13 *Size of sounding pipes*

3.10.13.1 Sounding pipes are not to be less than 32 mm in bore and those of heavy fuel oil tanks are not to be less than 50 mm in bore. Sounding pipes passing through compartments or spaces where the temperatures contemplated are 0℃ or below, are not to be less than 65 mm in bore.

Section 11 VENTILATION

3.11.1 *General requirements*

3.11.1.1 Machinery spaces of category A are to be adequately ventilated so as to ensure that when machinery or boilers therein are operating at full power in all weather conditions including heavy weather, an adequate supply of air is maintained to the spaces for the safety and comfort of personnel and the operation of the machinery.

Any other machinery space is to be adequately ventilated appropriate for the purpose of that machinery space. Ventilators of machinery spaces required to be continuously ventilated are to be of a height of coaming complying with the relevant requirements of 1.12.7.4(6), PART TWO of the Rules without having to fit weathertight closing appliances, so that they can be used in all weather conditions. However, where due to vessel size and arrangement this is not practicable, lesser heights for ventilator coamings may be accepted with provision of weathertight closing appliances in accordance with the requirements of 1.12.7.4(7), PART TWO of the Rules in combination with other suitable arrangements to ensure an uninterrupted, adequate supply of ventilation to these spaces.

3.11.1.2 All ventilator cowls for boiler rooms are to be fitted with rotating devices so that they may be turned and locked in any desired direction.

3.11.1.3 Effective means of ventilation are to be provided for all lamp-rooms, paint lockers and other compartments used for the storage of inflammable substances, explosives or where toxic or inflammable gases may accumulate.

3.11.1.4 When ventilation pipes pass through other compartments, relevant requirements on fire division and damage stability are to be complied with.

3.11.1.5 Ventilation system is to comply with the relevant requirements of PART SIX of the Rules.

3.11.2 *Ventilators*

3.11.2.1 The ventilators are to comply with the relevant requirements in 1.12.7.4, PART TWO of the Rules.

3.11.3 *Ventilator cowls*

3.11.3.1 Ventilator cowls are to be placed on the exposed deck and located as far from exhaust outlets, sky-lights and companionways as possible.

3.11.4 *Ventilation of emergency generator rooms*

3.11.4.1 The following requirements apply to ventilation louvers which can be closed for emergency generator rooms and to closing appliances where fitted to ventilators serving emergency generator rooms:

(1) Ventilation louvers and closing appliances may either be hand-operated or power-operated (hydraulic / pneumatic / electric) and are to be operable under a fire condition.

(2) Hand-operated ventilation louvers and closing appliances are to be kept open during normal operation of the vessel. Corresponding instruction plates are to be provided at the location where hand-operation is provided.

(3) Power-operated ventilation louvers and closing appliances are to be of a fail-to-open type. Closed power-operated ventilation louvers and closing appliances are acceptable during normal operation of the vessel. Power-operated ventilation louvers and closing appliances are to open automatically whenever the emergency generator is starting / in operation.

(4) It is to be possible to close ventilation openings by a manual operation from a clearly marked safe position outside the space where the closing operation can be easily confirmed. The louver status (open / closed) is to be indicated at this position. Such closing is not to be possible from any other remote position.

Section 12 ADDITIONAL REQUIREMENTS TO WATER LEVEL DETECTION AND DEWATERING OF FORWARD SPACES OF BULK CARRIERS

3.12.1 *Application*

3.12.1.1 This Section applies to classed bulk carriers of 500 gross tonnage and above and engaged on international voyages. The term bulk carrier referred to in this Section means a bulk carrier as defined in Chapter XII of the SOLAS Convention.

3.12.2 *Plans and documents*

3.12.2.1 The arrangement plan of dewatering system required by this Section is to be submitted for approval.

3.12.3 *Water level detection*

3.12.3.1 For water level detection and alarm system required to be installed in cargo hold, ballast tank and dry space, see the relevant requirements in Section 19, Chapter 2 of PART FOUR of the Rules.

3.12.4 *Dewatering system*

3.12.4.1 On bulk carriers, the means for drainage and pumping ballast tanks forward of the collision bulkhead, and bilges of dry spaces any part of which extends forward of the foremost cargo hold (excluding dry spaces the volume of which does not exceed 0.1% of the ship's maximum displacement volume and the chain locker), are to be capable of being brought into operation from a readily accessible enclosed space, the location of which is accessible from the navigation bridge or propulsion machinery control position without traversing exposed freeboard or superstructure decks. Where pipes serving such tanks or bilges pierce the collision bulkhead, the remote control position of valves specified in 2.8.1.3 of this PART is to comply with the requirements of this regulation.

The detailed arrangements of dewatering system are to satisfy following requirements:

(1) The enclosed spaces which are required to control dewatering system are to be accessible from the navigation bridge or propulsion machinery control position without traversing exposed freeboard or superstructure decks. A position which is accessible via an under deck passage, a pipe trunk or other similar means of access is not accepted.

(2) The dewatering arrangements are to be such that any accumulated water can be drained directly by a pump or ejector.

(3) Where the piping arrangements for dewatering closed dry spaces are connected to the piping arrangements for the drainage of water ballast tanks, two non-return valves are to be provided to prevent the ingress of water into dry spaces. One of these non-return valves is to be fitted with shut-off isolation arrangement. The non-return valves are to be located in readily accessible positions. The valve operation is to comply with all the requirements of this paragraph.

(4) The valve is not to move from the demanded position in the case of failure of the control system power or actuator power.

(5) Positive indication is to be provided at the remote control station to show that the valve is fully open or closed.
(6) Bilge wells are to be provided with gratings or strainers that will prevent blockage of the dewatering system with debris.
(7) The dewatering arrangements are to be such that when they are in operation, other systems essential for the safety of the ship including fire-fighting and bilge systems remain available and ready for immediate use. The systems for normal operation of electric power supplies, propulsion and steering are not to be affected by the operation of the dewatering systems. It must also be possible to immediately start fire pumps and have a ready available supply of fire-fighting water and to be able to configure and use bilge system for any compartment when the dewatering system is in operation.
(8) The enclosure of electrical equipment for the dewatering system installed in any of the forward dry spaces are to provide protection to IPX8① for a water head equal to the height of the space in which the electrical equipment is installed for a time duration of at least 24 h.

3.12.5 *Dewatering capacity*

3.12.5.1 The dewatering system is to be capable of quickly and efficiently removing water that may be accumulated in this space. The pump discharge capacity Q is not to be less than the value obtained from the following formula:

$$Q = 320A \quad m^3/h$$

where: A — the cross-sectional area of the largest ventilator pipe or air pipe serving this space and leading to the exposed deck, in m^2.

① See IEC Publication 60529.

CHAPTER 4 MACHINERY PIPING SYSTEMS

Section 1 GENERAL PROVISIONS

4.1.1 *Application*

4.1.1.1 Unless stated otherwise, the requirements of this Chapter apply to machinery piping systems for ships.

4.1.2 *Materials*

4.1.2.1 Except where otherwise stated in this Chapter, pipes, valves and fittings are to be made of steel, cast iron, copper, copper alloy, or other approved material suitable for the intended service.

4.1.2.2 Materials sensitive to heat, such as aluminum, lead or plastics, are not to be used in systems essential for the safety of the ship, or in systems conveying combustible liquids or sea water where leakage or failure could result in fire or in flooding of watertight compartments. For the use of plastic pipes, see the relevant requirements of 2.4.3 of this PART.

4.1.3 *Plans and documents*

4.1.3.1 The plans and documents to be submitted as required in this Chapter are referred to in 2.1.2 of this PART.

Section 2 OIL FUEL SYSTEMS

4.2.1 *General requirements*

4.2.1.1 Oil fuels for use in ships are to comply with the relevant provisions contained in 1.2.9 of this PART.

4.2.1.2 Drip trays are to be provided under the oil tanks which do not form part of the hull structure, pumps, filters, boiler burners and all other oil fuel appliances which are required to be opened up frequently for cleaning or adjustment. Oils in the drip trays are to be drained to special sludge tanks, and if the sludge tanks are situated in double bottom tank, shut-off valves or other reliable means of isolation are to be fitted to the drain pipes to prevent sea water entering tank through drain pipes after double bottom tank is damaged. Drain pipes are to be mutual independent from the tank overflow system.

4.2.1.3 The gaskets used for joining covers and manholes of fuel oil tanks and for joining the flanges of fuel pipes are to be made of oil-proof or heat-resistant material.

4.2.1.4 For motor ships burning oil fuel which has to be purified by purifiers, two oil fuel purification units and heating units are to be provided, one of which is a standby.

4.2.1.5 The spaces in which the burning appliances of boilers and the oil fuel settling and service tanks are fitted are to be well ventilated and easy of access.

4.2.1.6 In addition to the local controls, the power supply to all independently driven oil fuel transfer pumps, boiler oil fuel pumps, diesel engine fuel pumps and oil separators is to be capable of being stopped from a readily accessible position outside the spaces in which they are situated.

4.2.1.7 The oil fuel systems of diesel engines for heavy oil are to be provided with immediate change-over devices for diesel oil.

4.2.1.8 Two fuel oil service tanks or equivalent arrangements, for each type of fuel used on board, necessary for propulsion and essential systems are to be provided. Each tank is to have a capacity for at least 8 h operation at sea, at maximum continuous rating of the propulsion plant and normal operating load of the generating plant associated with that tank.

The arrangement of oil fuel service tanks is to be such that one tank can continue to supply oil fuel when the other is being cleaned or opened up for repair.

4.2.1.9 A service tank is a fuel oil tank which contains only fuel of a quality ready for use, i.e. fuel of a grade and quality that meet the specification required by the equipment manufacturer. A service tank is to be declared as such and not to be used for any other purpose. Use of a settling tank with or without purifiers, or purifiers alone, and one service tank is not acceptable as an “equivalent arrangement” to two service tanks. Examples of application for the most common systems are shown below:

(1) Example 1

① Requirement normally to be followed – main and auxiliary engines and boiler(s) operating with

heavy fuel oil (HFO) (one fuel ship)

HFO service tank Capacity for at least 8 h Main engine + Auxiliary engine + Auxiliary boiler	HFO service tank Capacity for at least 8 h Main engine + Auxiliary engine + Auxiliary boiler	MDO tank For initial cold starting or repair work of engines/boiler

② Equivalent arrangement

HFO service tank Capacity for at least 8 h Main engine + Auxiliary engine + Auxiliary boiler	MDO service tank Capacity for at least 8 h Main engine + Auxiliary engine + Auxiliary boiler

This arrangement only applies where main and auxiliary engines can operate with heavy fuel oil under all load conditions and, in the case of main engines, during manoeuvring.
For pilot burners of auxiliary boilers if provided, an additional marine diesel oil tank for 8 h may be necessary.

(2) Example 2

① Requirement normally to be followed – main engine(s) and auxiliary boiler(s) operating with HFO and auxiliary engine operating with marine diesel oil (MDO)

HFO service tank Capacity for at least 8 h Main engine + Auxiliary boiler	HFO service tank Capacity for at least 8 h Main engine + Auxiliary boiler	MDO service tank Capacity for at least 8 h Auxiliary engine	MDO service tank Capacity for at least 8 h Auxiliary engine

② Equivalent arrangement

HFO service tank Capacity for at least 8 h Main engine + Auxiliary boiler	MDO service tank Capacity for at least the highest of: • 4 h Main engine + Auxiliary engine + Auxiliary boiler, or • 8 h Auxiliary engine + Auxiliary boiler	MDO service tank Capacity for at least the highest of: • 4 h Main engine + Auxiliary engine + Auxiliary boiler, or • 8 h Auxiliary engine + Auxiliary boiler

The arrangements in (1) ② and (2) ② apply, provided the propulsion and vital systems which use two types of fuel support rapid fuel changeover and are capable of operating in all normal operating conditions at sea with both types of fuel (MDO and HFO).

4.2.2 *Oil burning units of boilers*

4.2.2.1 Auxiliary boilers for essential services in this Chapter are those for the purpose of supplying steam to auxiliary machineries as to ensure safe navigation of ships.

4.2.2.2 Main boilers and auxiliary boilers for essential services and for heating of heavy fuel oil are to have not less than two oil supply units, each unit generally comprising a pressure pump, a filter and a heater (if needed). The capacities and arrangements of the units are to be such that all the steam required for essential services can be maintained with any one unit out of action. Where an exhaust gas boiler is capable of supplying steam for essential purposes, a single oil supply unit may be accepted. For a composite boiler whose exhaust side can provide steam of essential services, a single oil supply unit may also be accepted.

4.2.2.3 Oil burning unit pressure pumps are to be entirely separate from the feed, bilge or ballast systems.

4.2.2.4 In systems where oil is fed to the burners by gravity, duplex filters are to be fitted in the supply pipeline to the burners.

4.2.2.5 A starting-up oil fuel unit, which does not require power from shore, is to be provided for main boilers.

4.2.2.6 Where boiler burners are provided with steam purging and/or atomizing connections, the arrangements are to be such that oil fuel cannot find its way into the steam system.

4.2.2.7 The burner arrangements are to be such that a burner cannot be withdrawn unless the oil fuel supply to that burner is shut out.

4.2.2.8 A quick-closing master valve is to be fitted to the oil supply to each boiler manifold, suitably located so that the valve can be readily operated in an emergency, either directly or by means of remote control. In the case of oil-fired boilers of automatic controls, the relevant requirements of PART SEVEN of the Rules are also to be complied with.

4.2.2.9 In the case of top-fired boilers, means are to be provided so that, in the event of flame failure, the oil fuel supply to the burners is shut off automatically, and audible and visual warnings are given. For small auxiliary top-fired boilers, this requirement may be dispensed with.
4.2.2.10 Provision is to be made, by suitable non-return arrangements, to prevent oil from spill systems being returned to the burners when the oil supply to these burners has been shut off.
4.2.2.11 For alternately fired furnaces of boilers using exhaust gases and oil fuel, the exhaust gas inlet pipe is to be provided with an isolating device and interlocking arrangements whereby oil fuel can only be supplied to the burners when the isolating device is closed to the boiler.

4.2.3 *Oil fuel pumps, filters and isolating valves*

4.2.3.1 Where an oil fuel booster pump is fitted, one main supply pump of sufficient capacity is to be provided for the main engine at its maximum continuous output and one standby pump of sufficient capacity is to be provided for normal navigation of the ship. Such a standby pump is to be independently power driven and capable of being ready for immediate use. Where two or more main engines are fitted, each with its own booster pump, only one standby pump connected ready for immediate use is needed, or alternatively, a complete spare pump may be accepted, provided that it is readily accessible and can easily be installed.
4.2.3.2 Where pumps are provided for fuel valve cooling, the arrangements of standby ones are to be in accordance with 4.2.3.1 of this Section.
4.2.3.3 Oil fuel filters are to be fitted in the oil fuel supply lines to the diesel engines, and their arrangement are to be such that any filter can be cleaned without interrupting the supply of filtered oil fuel to the engines.
4.2.3.4 Oil filters fitted in parallel for the purpose of enabling cleaning without distributing oil supply to engines (e.g. duplex filters) are to be provided with arrangements that will minimize the possibility of a filter under pressure being opened by mistake. Filters/filter chambers are to be provided with suitable means for venting when put into operation and depressurizing before being opened.
Valves or cocks with drain pipes led to a safe location are to be used for this purpose.
4.2.3.5 Where a power driven pump is necessary for transferring oil fuel, a standby pump is to be provided. Any suitable pump in connection with fuel transfer system may be accepted as the standby pump.
4.2.3.6 All pumps which are capable of developing a pressure exceeding the design pressure of the system are to be provided with relief valves. Each relief valve is to be so arranged as to discharge back to the suction side of the pump or other appropriate tanks, and to effectively limit the pump discharge pressure to the design pressure of the system.
4.2.3.7 Valves or cocks are to be interposed between the pumps and the suction and discharge pipes, in order that any pump may be shut off for opening up and overhauling.
4.2.3.8 In multi-engine installations which are supplied from the same fuel source, means of isolating the fuel supply and spill piping to individual engines are to be provided. The means of isolation are not to affect the operation of the other engines and are to be operable from a position not rendered inaccessible by a fire on any of the engines. The means of isolation are to be capable of reliable manual closing.
4.2.3.9 The redundancy requirements for fuel oil and hydraulic oil systems and electronic control system of electronically controlled diesel engine are to comply with the relevant requirements of paragraphs 2.1.3 and 2.2.3, Appendix 2, Chapter 9 of this PART.

4.2.4 *Oil fuel piping*

4.2.4.1 Oil fuel piping is to be entirely separate from other piping systems. The arrangements are to be such that oil cannot be admitted into tanks which are not structurally suitable for the carriage of oil or into tanks which are used for the carriage of fresh water. Where it is necessary to connect the fuel pipes to ballast systems, they are to be fitted with blanking flanges or other effective isolating devices.
4.2.4.2 Every oil fuel suction pipe from a double bottom tank is to be fitted with a valve or cock.
4.2.4.3 All valves and cocks forming part of the oil fuel installation are to be capable of being controlled from readily accessible positions above the working platform.
4.2.4.4 Oil fuel lines are not to be located immediately above or near units of high temperature, including boilers, steam pipelines, exhaust manifolds, silencers or other equipment required to be insulated by 1.3.6.3, Chapter 1 of this PART. As far as practicable, oil fuel lines are to be arranged far apart from hot surfaces, electrical installations or other sources of ignition and are to be screened or otherwise suitably protected to avoid oil spray or oil leakage onto the sources of ignition. The number of joints in such piping systems is to be kept to a minimum.
4.2.4.5 Pipes conveying heated oil to boilers under pressure are to be of seamless steel or other approved material having flanged or welded joints, and are to be placed in sight above the platform in well lighted

parts. The number of flanged joints is to be kept to a minimum. The flanges are to be machined. The jointing material is to be oil proof and impervious to oil heated to 150℃, and is to be as thin as possible. The scantlings of the pipes and their flanges are to be suitable for a pressure of at least 1.37 MPa or design pressure, whichever is the greater.

4.2.4.6 The short joining lengths of pipes to the burners from the control valves at the boiler may have threaded cone unions of robust construction.

4.2.4.7 Flexible hoses may be used for the burner pipes, provided that spare lengths, complete with couplings, are carried on board. Flexible hoses are to comply with the relevant requirements of 2.4.4 of this PART.

4.2.4.8 Oil fuel pipes and their valves and fittings are to be of steel or other equivalent material. Nodular graphite cast iron may be used for valves under static head fitted on the outside of fuel tank walls. Grey cast iron valves may be used in oil fuel piping with design pressure of less than 0.7 MPa and design temperature of less than 60℃.

Restricted use of flexible pipes is permissible in some positions. Flexible hoses are to comply with the relevant requirements of 2.4.4 of this PART.

4.2.5 *Oil fuel arrangements and fuel oil tanks*

4.2.5.1 As far as practicable, parts of the oil fuel system containing heated oil under pressure exceeding 0.18 MPa are not to be placed in a concealed position so that defects and leakage cannot readily be observed. The machinery spaces in way of such parts of the oil fuel system are to be adequately illuminated.

4.2.5.2 Every oil fuel pipe, which, if damaged, would allow oil to escape from a storage, settling or daily service tank situated above the double bottom are to be fitted with a cock or valve directly on the tank or short pipe welded to the oil tank bulkhead with a length not exceeding the value obtained from the following formula. Such valves or cocks are to be capable of being closed locally as well as cable of being closed from safe and easily accessible positions outside the spaces where these tanks are situated. In the case of tanks having a capacity of less than 0.5 m^3, remotely controlled closing devices may be omitted.

$$L = 0.8D + 80 \quad \text{mm}$$

where: L — length of short pipe, in mm;

D— outside diameter of steel pipe, in mm.

Remote shut-off control of oil fuel valves for emergency generating set and emergency fire pump is to be separated from those of other valves.

In the special case of deep tanks situated in any shaft or pipe tunnel or similar space, valves on the tank are to be fitted but control in the event of fire may be effected by means of an additional valve on the pipe or pipes outside the tunnel or similar space. If such additional valve is fitted in the machinery space it is to be operated from a position outside this space.

4.2.5.3 Where the filling pipes to deep oil tanks are not connected to the tanks near the top, they are to be provided with non-return valves at the tanks or with valves or cocks fitted and controlled as in 4.2.5.2 above.

4.2.5.4 Fuel oil tanks are not to be situated immediately above boilers or other highly heated surfaces. Precautions are to be taken to prevent any oil that may escape under pressure from any pump, filter or heater from coming into contact with heated surfaces.

4.2.5.5 As far as practicable, fuel oil tanks are to be part of the ship's structure and are to be located outside machinery spaces of category A. Where fuel oil tanks, other than double bottom tanks, are necessarily located adjacent to or within machinery spaces of category A, at least one of their vertical sides is to be contiguous to the machinery space boundaries, and is to preferably have a common boundary with the double bottom tanks, and the area of the tank boundary common with the machinery spaces are to be kept to a minimum.

Where such tanks are situated within the boundaries of machinery spaces of category A they are not to contain oil fuel having a flashpoint of less than 60℃ (closed cup test).

In general the use of free-standing fuel oil tanks is to be avoided. When such tanks are employed the use are to be prohibited in category A machinery spaces on passenger ships. Where permitted, they are to be placed in an oil-tight spill tray of ample size having a suitable drain pipe leading to a suitably sized spill oil tank.

4.2.5.6 Settling tanks are to be provided with means for draining water from the bottom of the tanks.

If settling tanks are not provided, the oil fuel bunkers or daily service tanks are to be fitted with water drains.

4.2.5.7 Drain valves or cocks fitted to the fuel oil tanks are to be of self-closing type, and suitable

provision is to be made for collecting the oily discharge.

4.2.5.8 In ships of 400 gross tonnage and above, oil is not to be carried in a forepeak tank or a tank forward of the collision bulkhead. All ships of less than 400 gross tonnage are to comply with the above mentioned provisions so far as it is reasonable and practicable.

4.2.5.9 Location of fuel tanks in cargo area on oil and chemical tankers

On oil and chemical tankers, carrying liquid cargoes having a flashpoint not exceeding 60℃ and/or toxic liquid cargoes[①] fuel tanks located with a common boundary to cargo or slop tanks are not to be situated within nor extend partly into the cargo tank block. Such tanks may, however, be situated aft and/or forward of the cargo tank block.

They may be accepted when located as independent tanks on open deck in the cargo area subject to spill and fire safety considerations.

The arrangement of independent fuel tanks and associated fuel piping systems, including the pumps, can be as for fuel tanks and associated fuel piping systems located in the machinery spaces. For electrical equipment, requirements to hazardous area classification must however be met.

Cargo tank block is the part of the ship extending from the aft bulkhead of the aftmost cargo or slop tank to the forward bulkhead of the forward most cargo or slop tank, extending to the full depth and beam of the ship, but not including the area above the deck of the cargo or slop tank as shown in Figure 4.2.5.9.

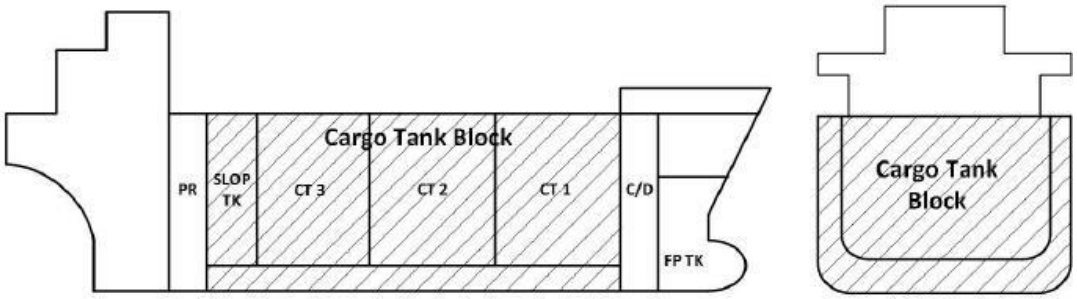

Figure 4.2.5.9

4.2.6 Filling piping

4.2.6.1 Fuel filling is to be effected by means of permanently installed lines. The filling pipes are to be led to a level as low as practicable inside the tank.

4.2.6.2 Where filling stations are fitted on board, they are to be isolated from other spaces and are to be efficiently drained and ventilated. Filling stations are to be so arranged that filling can be performed safely from both sides of the ship.

4.2.6.3 Provision is to be made against over-pressure in the filling pipelines, and any relief valve fitted for this purpose is to discharge to an overflow tank or other safe position.

4.2.7 *Oil fuel (lubricating oil) heating*

4.2.7.1 The heating media used for oil fuel (lubricating oil) tanks, heaters or oil separators are not to be more than 220℃ in temperature. Fuel oil (lubricating oil) in storage tanks is not to be heated to temperatures within 10℃ below the flash point of the fuel oil (lubricating oil), except that where oil fuel in service tanks, setting tanks and any other tanks in supply system is heated all of the conditions in 3.2.1.5(1) to (5) of Chapter 3 of PART SIX of the Rules are satisfied.

4.2.7.2 The exhaust drains from steam or hot water pipes used for heating the oil fuel (lubricating oil) are to be led to a separate observation tank in a well lighted and accessible position where it can be readily seen whether or not it is free from oil.

4.2.7.3 Relief valves are to be fitted on the oil side of heaters and the discharge from the relief valves is to be led to the suction of a related pump or to a safe position.

4.2.7.4 The oil fuel pipes and oil transfer pipes intended for conveying heated oil fuel are to be provided with suitable heating means if necessary.

4.2.7.5 Oil fuel (lubricating oil) tanks in which oil is heated and heaters are to be provided with suitable means for ascertaining the temperature of the oil.

4.2.7.6 Where steam heaters or heaters using other heating media are provided in fuel or lubricating oil

① Toxic liquid cargoes include those for which toxic vapour detection is specified in column “k” of the table of chapter 17 of the IBC Code.

systems, they are to be fitted with at least a high temperature alarm or low flow alarm in addition to a temperature control, except, where the temperature dangerous for the ignition of the medium cannot be reached.

4.2.7.7 Electric heating of fuel oil or lubricating oil are to be avoided as far as practicable.

When electric heaters are fitted, means are to be provided to ensure that heating elements are permanently submerged during operation. In order to avoid in any case element surface temperature of 220°C and above, a safety temperature switch, independent from the automatic control sensor, is to be provided. The safety switch is to cut off the electrical power supply in the event of excessive temperature, and is to be provided with manual reset.

4.2.7.8 The exhaust gas of diesel engines is not to be directly used for heating oil fuel.

4.2.8 *Alternative carriage of oil fuel and water ballast*

4.2.8.1 In general, in oil tankers of 150 gross tonnage and above, all passenger ships and other ships of 4,000 gross tonnage and above, no ballast water is to be carried in fuel oil tanks. Where it is necessary to carry ballast water in fuel oil tanks, suitable means are to be provided for preventing pollution of the sea by oily-water ballast.

4.2.8.2 Where it is intended to carry oil fuel and water ballast in the same compartments alternatively, each settling or service tank fitted is to have a capacity sufficient to permit 12 h normal service, otherwise the suction lines of these compartments are to be so arranged that the oil may be pumped from any one compartment by the oil fuel pump at the same time as the ballast pump is being used on any other compartment.

4.2.9 *Deep tanks for the alternative carriage of oil, water ballast or dry cargo*

4.2.9.1 In the case of deep tanks which can be used for the carriage of oil fuel, cargo oil, water ballast or dry cargo, blank flange or other positive means of closing is to be provided for isolating the oil and water ballast filling and suction pipes, also the steam heating coils if retained in place, when the deep tank is used for dry cargo, and for isolating the bilge suction pipes when the deep tanks are used for oil or water ballast.

4.2.9.2 If the deep tanks are connected to an overflow system, the arrangements are to be such that liquid or vapor from other tanks cannot enter the deep tanks when dry cargo is carried in them.

4.2.10 *Separation of cargo oils from oil fuel*

4.2.10.1 Pipes conveying vegetable oils or similar cargo oils are not to be led through fuel oil tanks, nor are oil fuel pipes to be led through tanks containing these cargo oils.

4.2.11 *Arrangements for other flammable oils*

4.2.11.1 The arrangements for the storage, distribution and utilization of other flammable oils employed under pressure in power transmission systems, control and activating systems and heating systems are to be such as to ensure the safety of the ship and persons on board. In locations where means of ignition are present, such arrangements are at least to comply with the provisions of 4.2.4.8 and 4.2.5.4 of this Section, and with the relevant provisions contained in Section 10 of Chapter 3 of this PART.

Section 3 STEAM PIPING SYSTEMS

4.3.1 *Arrangement*

4.3.1.1 In general, steam pipes are not to be led through lamp rooms, paint lockers and cargo spaces, but where it is impracticable to avoid this arrangement, the pipes in way of cargo spaces are to be well protected from mechanical damage, and pipe joints are to be as few as practicable and preferably butt welded.

4.3.1.2 Where steam pipes subject to a working pressure exceeding 0.98 MPa are placed near to the fuel oil tank, the clearance space between the pipe and the external surface of the tank is in general to be at least 250 mm.

4.3.1.3 Steam pipes are to be arranged in visible and accessible positions in the machinery spaces. Steam pipes, except those used for preheating and sea chest blow-off services, are in general not to be led under the floor plates in machinery spaces.

4.3.1.4 Where two or more boilers are interconnected by steam pipe or pipes, a screw-down non-return valve is to be provided in the steam pipe of each boiler. Valves intended to drain condensate are to be fitted in the pipe length between these valves.

4.3.2 *Condensate drainage*

4.3.2.1 The slope of the pipes and the number and position of the drain valves or cocks are to be such that water can be efficiently drained from any portion of the steam piping system when the ship is in normal trim and is either upright or has a list of up to 5°. Arrangements are to be made for ready access to the drain valves or cocks.

A by-pass line is to be provided where the condensate trap is installed.

4.3.3 *Thermal expansion stresses*

4.3.3.1 For steam pipes subject to a working temperature exceeding 350°C, special consideration is to be given to stress due to thermal expansion and to technique of installation.

Section 4 FEED, BLOW-OFF AND CONDENSATE SYSTEMS

4.4.1 *Feed pumps*

4.4.1.1 Two or more power driven feed pumps are to be provided for main and auxiliary boilers for essential services or steam auxiliary boilers for heating heavy oil. These feed pumps are to be of sufficient capacity to supply the boilers under full load conditions with any one pump out of action.

4.4.1.2 Forced circulation boilers are to be provided with two independently driven circulating pumps, one of which is used as a stand-by pump. For auxiliary forced circulation boilers not used for essential services, one circulating pump will be accepted.

4.4.1.3 Where a harbor feed pump is provided, it may be used for other purposes, but in no case is it to be used for oil transferring or for discharging oily bilges. Furthermore, a suitable arrangement is to be provided to prevent the contamination of feed from sea water.

4.4.2 *Feed piping*

4.4.2.1 Two feed water systems are to be provided for main and auxiliary boilers for essential services, including feed pumps. The feed systems are to be of sufficient capacity to supply feed water to the boilers with any one system out of action. Only one feed water system may be provided for steam generators heated by steam where the steam for essential services is capable of being supplied simultaneously from another sources.

Feed water systems are to be so arranged that the feed water cannot be contaminated by oil or oily water.

4.4.2.2 Valves or cocks are to be interposed between the pumps and the suction and discharge pipes, so that any pump may be shut off and opened up for overhaul.

4.4.3 *Reserve feed water*

4.4.3.1 All ships fitted with main boilers and auxiliary boilers for essential services are to be provided with tanks of sufficient capacity for reserve feed water.

4.4.3.2 For main boilers in ships, one or more evaporators of adequate capacity are to be provided to cover the losses of feed water in the system. In the case of auxiliary boilers for essential services in ships, evaporators are to be installed as necessary.

4.4.4 *Condensate pumps*

4.4.4.1 At least two power driven condensate pumps, one of which is a standby pump, are to be provided for dealing with the condensate from the main and auxiliary condensers. Independent feed pumps may be accepted as stand-by condensate pumps.

4.4.5 *Blow-off piping*

4.4.5.1 The internal diameter of the blow-off pipes is to comply with the requirements of 6.3.7.2 of this PART. Valves or cocks in the blow-off piping, situated at the ship's bottom or ship's sides, are to be arranged and constructed according to the provisions contained in 2.8.9.2 and 2.8.9.3 of this PART.

4.4.5.2 The blow-off pipes of two or more boilers may be connected to a common discharge, but the blow-off pipe for each boiler is to be fitted with a non-return valve. It is recommended that a throttle washer be fitted to the blow-off pipe.

Section 5 COOLING WATER SYSTEMS

4.5.1 *Cooling water pumps*

4.5.1.1 For motor ships, where only one main engine is fitted, a main cooling pump of sufficient capacity to maintain supply of water at the maximum continuous output of the machinery and a standby cooling pump of sufficient capacity to supply cooling water under the normal navigating condition are to be provided. The standby pump is to be of independently power-driven type and to be connected ready for use. Where more than one main engine is fitted, each with its own cooling water pump, a complete spare pump may be accepted as a standby cooling water pump.

4.5.1.2 In steam ships, in addition to the main circulating pump for the condenser, there is to be an alternative supply from an emergency pump having a capacity sufficient to maintain the proper control of the ship (in general not to be less than 30% of that of the main circulating pump). If the main circulating pump unit consists of two independently power-driven pumps of approximately equal capacity, the emergency pump may be dispensed with.

Where a sea inlet scoop arrangement is fitted in lieu of the main circulating water pump, in addition to one independently power-driven circulating water pump having a capacity of at least 30% of that of the maximum required by circulation, a connection to the largest available pump suitable for circulation duties is to be fitted to provide the second means of circulation when the ship is maneuvering.

4.5.1.3 Where each essential auxiliary engine is fitted with a built-in cooling water pump, the standby pump may be dispensed with. If two or more auxiliary engines are supplied with cooling water from a common system, a standby cooling water pump is needed. The standby cooling water pump may be substituted by other pumps of sufficient capacity.

4.5.1.4 Where fresh water cooling is employed for main and/or auxiliary engines, a standby fresh water pump need not be fitted if there are suitable emergency connections from a salt water system.

4.5.2 *Piping and fittings*

4.5.2.1 The cooling water piping for diesel engines is to be capable of effectively regulating the inlet cooling water temperature. For closed circuit fresh water cooling system, expansion tanks are to be provided and it is recommended that an alarm for high temperature be fitted.

4.5.2.2 Where cooling water pumps can develop a pressure head greater than the design pressure of the system, they are to be provided with relief valves on the pump discharge. When discharge from the relief valves is to find its way into the bilge, the valves are to be fitted in readily visible positions above the floor. The arrangement is to be such that any discharge from the relief valves will also be readily visible.

4.5.2.3 Not less than two sea inlets, which are to be fitted on both sides of the ship as far as practicable, are to be provided for the cooling water pumps of sea water cooling system or circulating system. The suction of any cooling water pump or circulating pump under normal service conditions is to be supplied from either one of the sea inlets.

4.5.2.4 Provision is to be made for the protection of all equipment cooled by sea water against corrosion.

4.5.2.5 Strainers are to be provided to the suction pipes between the sea inlets and the suctions of sea water cooling pumps. The strainers are to be so arranged that they can be cleaned without interrupting the cooling water supply.

4.5.2.6 When it is necessary, the main diesel engine with closed circuit fresh water cooling system is to be provided with suitable means for warming the engine before starting. Alternatively, means to inter-connect the fresh water cooling system for main engine to that for auxiliary engines are acceptable.

Section 6 LUBRICATING OIL SYSTEMS

4.6.1 *Lubricating oil pumps*

4.6.1.1 Main engines and their transmission gearing are to be provided with a main lubricating oil pump of sufficient capacity to maintain supply of lubricating oil at the maximum continuous output of the machinery and a standby pump of sufficient capacity to supply lubricating oil under normal navigating condition are to be provided. The standby pump is to be of independently power-driven type and to be connected ready for use.

For ships fitted with more than one main engine, only one independently power-driven standby pump fitted is acceptable. Where each main engine and its transmission gearing is fitted with a built-in lubricating oil pump, a complete spare pump available for installation and connection may be accepted as an independently power-driven standby pump.

4.6.1.2 Where each essential auxiliary engine and its transmission gearing is fitted with a built-in lubricating oil pump, the standby pump may be dispensed with. If two or more auxiliary engines and their transmission gearing are connected to a common lubricating oil system, a standby pump is needed.

4.6.2 *Piping and fittings*

4.6.2.1 The lubricating oil piping is to be entirely separate from other piping systems. A common lubricating oil system is not to be in use for diesel engines and gear boxes.

4.6.2.2 Provision is to be made for the efficient filtration of the lubricating oil. For main propulsion machinery, the filters are to be capable of being cleaned without interrupting normal supply of filtered oil required in normal operation of ships. For generating sets, the filters are to be capable of being cleaned without interrupting normal supply of filtered oil required by generating sets under normal work load. Pressure gauges are to be fitted on both ends of lubricating oil filters or strainers. Proposals for fitting an emergency automatic by-pass device in high speed engines are to be submitted to ISC for special consideration.

Magnetic strainers are to be provided for high-powered main turbines and their reduction gears.

4.6.2.3 A relief valve is to be fitted on the lubricating oil pump discharge if the pump is capable of developing a pressure exceeding the design pressure of the system. The relief valve is to be such that the discharge oil can find its way to the suction of the pump and the pump discharge pressure is to be effectively limited to the design pressure of the system.

4.6.2.4 Visual and audible alarms are to be provided to give warning of an appreciable reduction in pressure of the lubricating oil.

4.6.2.5 Where two or more diesel engines are fitted, the drain pipes leading from the engine sumps to the lubricating oil drain tanks are to be independent to avoid intercommunication between crankcases.

4.6.3 *Additional requirements for lubricating oil systems of main turbines and main turbo-generators*

4.6.3.1 For main turbines and main turbo-generators in electrically propelled ships, a suitable emergency supply of lubricating oil is to be arranged. For this purpose, either one of the following will be accepted:

(1) The emergency supply may be obtained from a gravity tank holding sufficient lubricating oil to maintain adequate lubrication for not less than 5 min for main turbines, and, in the case of main turbo-generators, until the unloaded turbine comes to rest from the maximum rated running speed. The gravity tank is to be arranged to come automatically into use in the event of a failure of the lubricating oil pump. An alarm device is to be fitted to the gravity tank to give visual and audible warning when the oil in the tank falls to a predetermined level.

(2) The emergency supply may be obtained from a standby pump or an emergency pump. These pumps are to be so arranged that their availability is not affected by a failure in the main power supply and that they are capable of coming automatically into use.

4.6.3.2 Overflow pipes, which are to be led to the lubricating oil drain tanks, are to be fitted to the gravity tanks and the cross-sectional area of the overflow pipes is not to be less than 1.25 times that of the filling pipes from the lubricating oil pumps. The overflow pipes are to be fitted with illuminated sight glasses.

4.6.4 *Lubricating oil arrangements and lubricating oil tanks*

4.6.4.1 The separation of lubricating oil tanks from adjacent tanks is to be in compliance with the requirements of 2.8.2.1 of this PART.

4.6.4.2 The capacity of lubricating oil drain tanks is to be sufficient to hold the oil in the whole system. Where an engine lubricating oil drain tank extends to the bottom shell plating in ships that are required to be provided with a double bottom, a shut-off valve is to be fitted in the drain pipe between the engine casing and the double bottom tank. This valve is to be capable of being closed from an accessible position above the level of the lower platform. If the drain tanks in the double bottom are separated from the shell plating by cofferdams, the shut-off valve mentioned above may be dispensed with.

The oil inlet pipe of the drain tank is to be extended to an adequate depth below the lowest working level and is to be located as wide apart from the outlet as practicable.

4.6.4.3 The pressure lubrication systems are to comply with the requirements of 4.2.4.4, 4.2.4.8, 4.2.5.1, 4.2.5.2, 4.2.5.4 and 4.2.6.3 of this Chapter and the relevant provisions contained in Section 10 of Chapter 3 of this PART.

In the case of tanks having a capacity of less than 0.5 m^3, consideration will be given to the omission of remote controls.

If the designers confirm that an unauthorized operation of the remotely controlled closing valves on the lubricating tanks will jeopardize safe running of the main or eventful auxiliary engines, the remotely

controlled device may be omitted.
4.6.4.4 All ships are to be provided with lubricating oil storage tank(s) having an adequate capacity.
4.6.4.5 Heating of lubricating oil is to comply with the relevant requirements of 4.2.7 of this Chapter.

Section 7 HYDRAULIC TRANSMISSION PIPING SYSTEMS

4.7.1 *Materials*

4.7.1.1 All components in the hydraulic transmission piping systems are to be made of materials which are not corrodible and have no chemical reaction with the hydraulic fluid.
4.7.1.2 The hydraulic fluid is to be of high chemical stability and of good viscosity-temperature property.
4.7.1.3 Main components in hydraulic power transmission system are to be generally made of steel materials. Material test is to be carried out according to the requirements of ISC Rules for Materials and Welding.

4.7.2 *Piping*

4.7.2.1 The hydraulic transmission piping is not to be used for the lubrication of other equipment.
4.7.2.2 The strength of hydraulic pipes and fittings is to be sufficient to withstand the pressure fluctuations which might occur in the system.
4.7.2.3 Strainers and relief valves are to be provided in the hydraulic transmission piping systems. The discharge from the relief valves is in general to be led to the hydraulic fluid tanks.
4.7.2.4 Provision is to be made for de-aeration in the hydraulic piping systems and the hydraulic fluid cylinders, etc. The hydraulic piping is to be so arranged as to avoid the formation of air pockets.
4.7.2.5 Where hydraulic accumulators are provided in the hydraulic systems, overflow valves are to be fitted on the liquid side. Unless otherwise specified, for hydro-pneumatic accumulators, safety valves or fuse plugs are to be fitted on the air side, otherwise they are to be fitted in the supply pipe line, and an isolation valve is not to be provided between the air side of the accumulator and the safety valve or fuse plug.
4.7.2.6 The use of flexible hoses is to comply with the relevant requirements of 2.4.4 of this PART. The flexible hoses are to be so arranged that abrupt bends and twisting will not occur in the laying of the hoses and they are to be far away from vibration and hot sources.
4.7.2.7 Hydraulic remote control valves for essential service are to be capable of being operated with a hand pump in emergency condition, and indicators showing whether the valves are open or closed are to be provided at their operating positions.
4.7.2.8 The hydraulic transmission piping system for essential services is to be provided with a standby power pump which is to be capable of immediate use.

4.7.3 *Arrangement*

4.7.3.1 Hydraulic units with working pressure above 1.5 MPa are to be placed in separate spaces. If it is impracticable to locate such units in a separate space, adequate shielding is to be provided.

Section 8 THERMAL OIL SYSTEM

4.8.1 *General requirements*

4.8.1.1 The thermal oil used in the thermal oil system is to be compatible with the oil being heated.
4.8.1.2 Heating of liquid cargoes with flash points below 60℃ is to be arranged by means of a separate secondary system, located completely within the cargo area. However, a single circuit system may be accepted on the following conditions:
(1) System is so arranged that a positive pressure in the coil is to be at least 3 m water column above the static head of the cargo when circulating pump is not in operation.
(2) The thermal oil system expansion tank is to be fitted with high and low level alarms.
(3) Means are to be provided in the thermal oil system expansion tank for detection of flammable cargo vapors.
(4) Valves for the individual heating coils are to be provided with locking arrangement to ensure that the coils are under static pressure at all times.
4.8.1.3 For details of heaters in thermal oil systems, see the relevant requirements of Section 5, Chapter 6 of this PART.

4.8.2 *Plans and documents*

4.8.2.1 The piping and pumping system plans of thermal oil systems are to be submitted for approval.

4.8.3 *Design and manufacture*

4.8.3.1 The installation is generally to comprise at least two circulation pumps and two filters for the thermal oil.

4.8.3.2 In addition to the local operations, the inlet and outlet valves of oil-fired thermal oil heaters and exhaust-fired thermal oil heaters are to be shut off from a readily accessible position outside the compartment where they are situated. As an alternative, an arrangement for quick gravity drainage of the thermal oil contained in the system into a collecting tank is acceptable.

4.8.3.3 Arrangements are to be provided to permit from inside and from outside the heater spaces a quick discharge by gravity of the expansion tank into a suitable tank.

4.8.3.4 The monitoring and protection of thermal oil heaters are to comply with the relevant requirements of 6.5.5, Chapter 6 of this PART.

4.8.3.5 Tubes and pipes for thermal oil are to be seamless steel tubes or welded steel tubes and pipes.

4.8.3.6 Casings of pumps, valves and similar components are to be made of steel or equivalent ductile material. Copper and copper alloys are not to be used for those parts the surface of which is in direct contact with thermal oil so as to prevent oxidation of thermal oil.

4.8.3.7 Thermal oil piping is to have welded connections except that flanges may be used to the limited number necessary for inspection and maintenance. If necessary, suitable devices are to be provided for avoiding oil splash in case of leakage in way of the flanges. Marine steel recess type or plane flanges having a nominal pressure not less than 1.6 MPa are to be used for inlet and outlet pipe connection of thermal oil heaters. In the case of steel plane flanges, wire-reinforced graphite gaskets or expanded graphite composite gaskets are to be used.

Screw joints are not to be used for thermal oil piping.

4.8.3.8 The piping system is to be designed and constructed to permit expansion and contraction without abnormal stressing.

4.8.3.9 Particular attention is to be paid to the insulation of thermal oil piping and heater. Flanges are not permitted to be protected by the insulation material. Insulation material of thermal oil heater and piping is to be of an approved type and, as far as possible, it does not lower than the auto-ignition point of the thermal oil when impregnated by it.

4.8.3.10 The thermal oil system is also to comply with the requirements contained in the relevant Chapters of the Rules.

4.8.4 *Arrangement*

4.8.4.1 Where the thermal oil heaters are located in main and auxiliary machinery spaces, effective means are to be provided to prevent dispersal of thermal oil after leakage, such as coaming plate, etc.

4.8.4.2 The thermal oil circulating pumps are to be arranged for emergency stopping from a position outside the space where they are situated.

4.8.4.3 Drip trays are to be installed under the components of the installation where leakage is liable to occur. These drip trays are to be drained to an appropriate sludge tank.

4.8.4.4 The thermal oil system is to be fitted with an expansion tank of sufficient capacity. The thermal oil expansion tank and pumping plants are to be located in the same space as the thermal oil heaters.

4.8.4.5 Vents from expansion tanks and thermal oil storage tanks of the thermal oil heating plants are to be led to open deck.

4.8.4.6 Thermal oil piping and pumping system are to comply with the relevant requirements of Section 2 of this Chapter. Only one pump supplying thermal oil to the thermal oil expansion tank is acceptable.

4.8.4.7 Thermal oil pipes are not to pass through accommodation spaces nor control stations. Thermal oil piping passing through main and auxiliary machinery spaces is to be restricted as far as possible.

4.8.4.8 Thermal oil heater rooms are to be suitably mechanically ventilated and illuminated.

4.8.4.9 Thermal oil heater rooms are to be fitted with approved automatic fire detection system or fire alarm system.

4.8.5 *Additional requirements for exhaust-fired thermal oil heaters*

4.8.5.1 Exhaust-fired thermal oil heaters are also to comply with the relevant requirements of 6.5.4.5 and 6.5.4.6, Chapter 6 of this PART.

4.8.6 *Testing*

4.8.6.1 Thermal oil system and installation are to be subject to hydraulic and tightness tests according to the relevant requirements contained in Chapters 2 and 6 of this PART.
4.8.6.2 On completion, working tests of the thermal oil system are to be carried out in accordance with the test program.

Section 9 REQUIREMENTS CONCERNING USE OF CRUDE OIL OR SLOPS AS FUEL FOR TANKER BOILERS

4.9.1 *General requirements*

4.9.1.1 In tankers crude oil or slops may be used as fuel for main or auxiliary boilers according to the following requirements. For this purpose all arrangement drawings of a crude oil installation with pipeline layout and safety equipment are to be submitted for approval in each case.
4.9.1.2 Crude oil or slops may be taken directly from cargo tanks or flow slop tanks or from other suitable tanks. These tanks are to be fitted in the cargo tank area and are to be separated from non-gas-dangerous areas by means of cofferdams with gas-tight bulkheads.
4.9.1.3 The construction and workmanship of the boilers and burners are to be proved to be satisfactory in operation with crude oil.
The whole surface of the boilers is to be gas-tight separated from the engine room. The boilers are to be tested for gas-tightness before being used. The whole system of pumps, strainers, separators and heaters, if any, is to be fitted in the cargo pump room or in another room, to be considered as dangerous, and separated from engine and boiler room by gas-tight bulkheads. When crude oil is heated by steam or hot water the outlet of the heating coils is to be led to a separate observation tank installed together with above mentioned components. This closed tank is to be fitted with a venting pipe led to the atmosphere in a safe position according to the provisions for tankers and with the outlet fitted with a suitable flameproof wire gauze of corrosion resistant material which is to be easily removable for cleaning.
4.9.1.4 Electric, internal combustion and steam (when the steam temperature is higher than 220°C) prime movers of driving pumps, of separators (if any) are to be fitted in the engine room or in another non-dangerous room.
Where drive shafts pass through pump room bulkhead or deck plating, gas-tight glands are to be fitted. The glands are to be efficiently lubricated from outside the pump room.
4.9.1.5 Pumps are to be fitted with a pressure relief by-pass from delivery to suction side and it is to be possible to stop them by a remote control placed in a position near the boiler fronts or machinery control room and from outside the engine room.
4.9.1.6 When it is necessary to preheat crude oil or slops, their temperature is to be automatically controlled and a high temperature alarm is to be fitted.

4.9.2 *Arrangement*

4.9.2.1 The piping for crude oil or slops and the draining pipes for the tray defined in 4.9.2.3 are to have a thickness as shown in Table 4.9.2.1.

External diameter and thickness of crude oil, slops and draining pipes (mm)

Table 4.9.2.1

External diameter d_e	Wall thickness t
$d_e \leq 82.5$	≥ 6.3
$88.9 < d_e \leq 108$	≥ 7.1
$114.3 < d_e \leq 139.7$	≥ 8.0
$152.4 \leq d_e$	≥ 8.8

Their connections (to be reduced to a minimum) are to be of the heavy flange type. Within the engine room and boiler room these pipes are to be fitted within a metal duct, which is to be gas-tight and tightly connected to the fore bulkhead separating the pump room and to the tray. This duct (and the enclosed piping) is to be fitted at a distance from the ship's side of at least 1/5 of the vessel's beam (B) amidships and be at an inclination rising towards the boiler so that the oil naturally returns towards the pump room in the case of leakage or failure in delivery pressure. It is to be fitted with inspection openings with gas-tight doors in way of connections of pipes within it, with an automatic closing drain-trap placed on the pump room side, set in such a way as to discharge leakage of crude oil into the pump room.
In order to detect leakages, level position indicators with relevant alarms are to be fitted on the drainage tank defined in 4.9.2.3. Also a vent pipe is to be fitted at the highest part of the duct and is to be led to the open in a safe position. The outlet is to be fitted with a suitable flameproof wire gauze of

corrosion-resistant material which is to be easily removable for cleaning.
The duct is to be permanently connected to an approved inert gas system or steam supply in order to make possible:
(1) injection of inert gas or steam in the duct in case of fire or leakage;
(2) purging of the duct before carrying out work on the piping in case of leakage.
4.9.2.2 In way of the bulkhead to which the duct defined in 4.9.2.1 is connected, delivery and return oil pipes are to be fitted on the pump room side, with shut-off valves remotely controlled from a position near the boiler fronts or from the machinery control room. The remote control valves are to be interlocked with the hood exhaust fans (defined in 4.9.3.1) to ensure that whenever crude oil is circulating the fans are running.
4.9.2.3 Boilers are to be fitted with a tray or gutterway with a suitable height and be placed in such a way as to collect any possible oil leakage from burners, valves and connections.
Such a tray or gutterway is to be fitted with a suitable flameproof wire gauze, made of corrosion resistant material and easily dismountable for cleaning. Delivery and return oil pipes are to pass through the tray or gutterway by means of a tight penetration and are then to be connected to the oil supply manifolds.
A quick closing master valve is to be fitted on the oil supply to each boiler manifold.
The tray or gutterway is to be fitted with a draining pipe discharging into a collecting tank in pump room. This tank is to be fitted with a venting pipe led to the open in a safe position and with the outlet fitted with wire gauze made of corrosion resistant material and easily dismountable for cleaning. The draining pipe is to be fitted with arrangements to prevent the return of gas to the boiler or engine room.

4.9.3 *Other requirements*

4.9.3.1 Boilers are to be fitted with suitable hood in such a way as to enclose as much as possible of the burners, valves and oil pipes, without preventing on the other side, air inlet to burner register.
The hood, if necessary, is to be fitted with suitable doors placed in such a way as to enable inspection of and access to oil pipes and valves placed behind it. It is to be fitted with a duct leading to the open in a safe position, the outlet of which is to be fitted with a suitable flameproof wire gauze, easily dismountable for cleaning. At least two mechanically driven exhaust fans having spark proof impellers are to be fitted so that the pressure inside the hood is less than that in the boiler room. The exhaust fans are to be connected with automatic change over in case of stoppage or failure of the one in operation.
The exhaust fan prime movers are to be placed outside the duct and a gas-tight bulkhead penetration is to be arranged for the shaft.
Electrical equipment installed in gas dangerous areas or in areas which may become dangerous (i.e. in the hood or duct in which crude-oil piping is placed) is to be of certified safe type as required by ISC.
4.9.3.2 When using fuel oil for delivery to and return from boilers, fuel oil burning units are to be fitted in the boiler room. Fuel oil delivery to, and returns from, burners are to be effected by means of a suitable mechanical interlocking device so that running on fuel oil automatically excludes running on crude oil or vice versa.
4.9.3.3 The boiler compartments are to be fitted with a mechanical ventilation plant and are to be designed in such a way as to avoid the formation of gas pockets.
Ventilation is to be particularly efficient in way of electrical plants and machinery and other plants which may generate sparks. These plants are to be separated from those for service of other compartments and are to be in accordance with relevant requirements of ISC.
4.9.3.4 A gas detector plant is to be fitted with intakes in the duct defined in 4.9.2.1 of this Section, in the hood duct (downstream of the exhaust fans in way of the boilers) and in all zones where ventilation may be reduced. An optical warning device is to be installed near the boiler fronts and in the machinery control room. An acoustical alarm, audible in the machinery space and control room, is to be provided.
4.9.3.5 Means are to be provided for the boiler to be automatically purged before firing.
4.9.3.6 Independent of the fire extinguishing plant as required in the Rules, an additional fire extinguishing plant is to be fitted in the engine and boiler rooms in such a way that it is possible for an approved fire extinguishing medium to be directed on to the boiler fronts and on to the tray defined in 4.9.2.3 of this Section. The emission of extinguishing medium is automatically to stop the exhaust fan of the boiler hood.
4.9.3.7 A warning notice is to be fitted in an easily visible position near the boiler front. This notice is to specify that when an explosive mixture is signaled by the gas detector plant defined in 4.9.3.4, the watchkeepers are to immediately shut off the remote controlled valves on the crude oil delivery and return pipes in the pump room, stop the relative pumps, inject inert gas into the duct defined in 4.9.2.1 of this Section and turn the boilers to normal running on fuel oil.
4.9.3.8 One pilot burner in addition to the normal burning control is required.

Section 10 EXHAUST PIPELINES

4.10.1 *Arrangement*

4.10.1.1 Uptakes of boilers except exhaust gas boilers are not to be connected with exhaust pipelines of diesel engines.

4.10.1.2 Uptake governors or other means for closing the uptakes are not to be fitted within uptakes or funnels of oil-fired boilers.

4.10.2 *Silencers*

4.10.2.1 The structure of silencers is to be so designed that the internal cleaning and inspection can be carried out easily and these silencers are to be fitted with washing units with compressed air or steam or other cleaning appliances and drainage valves or cocks.

4.10.2.2 The external portion of silencers are to be packed with thermal insulation materials.

4.10.3 *Water heaters*

4.10.3.1 Water heaters fitted on the ducts for exhaust gas and smoke are, in general, to be of open type. If close type water heaters are fitted, the strength calculation is to be in accordance with the relevant requirements in Chapter 6 of this PART.

4.10.3.2 Close type water heaters are to be fitted with relief valves, pressure gauges, water level indicators, etc.

4.10.3.3 On construction, the close type water heaters are to be subject to a hydraulic test of 1.5 times the design pressure and the test pressure is not to be less than 0.4 MPa. The test of relief valves is to be carried out in accordance with the requirements in 6.3.5.3 of this PART.

4.10.3.4 Open type water heaters are to be fitted with a vent pipe of sufficient diameter and the vent pipe is not to be fitted with any closing appliances.

CHAPTER 5 PIPING SYSTEM FOR OIL TANKERS

Section 1 GENERAL PROVISIONS

5.1.1 *Application*

5.1.1.1 The requirements of this Chapter apply to oil tankers having the main propelling machinery aft which are intended to carry crude oil and petroleum products having a flash point (closed cup test) not exceeding 60℃.

Where ships are intended for the carriage of cargo oil having a flash point (closed cup test) exceeding 60℃, the relevant requirements in Section 8 of this Chapter are to be complied with.

5.1.1.2 In addition to the requirements of this Chapter, piping systems for oil tankers are to comply with the relevant provisions contained in Chapters 2, 3 and 4 of this PART, where applicable.

5.1.2 *Arrangement of dangerous spaces*

5.1.2.1 Diesel engines, or any other equipment which could constitute a possible source of ignition, are not to be situated within cargo tanks, pump rooms, cofferdams or other spaces liable to contain cargo oil or explosive vapors, or in spaces or zones immediately adjacent to cargo oil or slop tanks. The temperature of steam, or other fluid, in pipes (or heating coils) in these spaces is not to exceed 220℃.

5.1.3 *Steam connections to cargo tanks*

5.1.3.1 Where steaming out connections are provided for cargo tanks or cargo pipelines, they are to be fitted with valves of the screw-down non-return type. The main supply to these connections is to be fitted with a master valve placed in a readily accessible position clear of the cargo tanks.

The steaming pipes are to be so arranged that the steam can be supplied to the upper and lower parts of the tank separately as necessary.

5.1.4 *Cargo pump room*

5.1.4.1 Cargo pump rooms are to be situated within, or adjacent to, the cargo tank area and are to be provided with ready means of access on open deck.

Pump rooms are to be totally independent of and to have no direct communication with machinery spaces.

5.1.4.2 In cargo pump rooms any drain pipes from steam or exhaust pipes or from the steam cylinders of the pumps are to terminate well above the level of the bilges.

5.1.5 *Slop tanks*

5.1.5.1 In oil tankers, the venting arrangement, level sounding devices, heating systems and the piping for conveying oily water and cargo oil for the slop tanks designated for collecting and treating tank washings and dirty ballast from cargo tanks and other oily water are to comply with the relevant requirements for cargo tanks.

5.1.5.2 Discharge of oily water from slop tanks is to comply with the provisions for the prevention of pollution from ships.

5.1.6 *Gas freeing equipment*

5.1.6.1 Provision is to be made for the gas freeing of cargo tanks when the cargo has been discharged, and for the ventilation and gas freeing of all compartments adjacent to cargo tanks. For the purpose of monitoring flammable vapor, portable instruments are to be available on board for gas detection.

5.1.7 *Earthing of cargo oil pipes*

5.1.7.1 Earthing and bonding of cargo tanks and piping systems for the control of static electricity is to comply with the requirements in 1.3.4.11 of PART FOUR of the Rules.

5.1.8 *Prevention and free of spark*

5.1.8.1 The outlets of the exhaust gas pipes for main and auxiliary engines, boilers and other burner equipment are to be located at the sufficient height above the main deck. The horizontal distance of the outlets from cargo area is not to be less than 10 m. Where internal combustion engine is provided with approved spark arresters, as well as boilers and other burner equipment to be provided with spark arresters, their distance may be reduced to 5 m.

Section 2 CARGO HANDLING SYSTEM

5.2.1 *General requirements*

5.2.1.1 At least two independently power-driven cargo oil pumps are to be connected to the cargo oil system to pump cargo oil in each cargo tank. The arrangement is to ensure that the operation of other pumps is not affected if any one of the cargo oil pumps is inoperable.

5.2.1.2 If the cargo in cargo tank is lightered by a single deep well pump installed in each cargo tank, an emergency means for pumping out the tank is to be provided in case of failure of deep well pump.

5.2.2 *Cargo pumps*

5.2.2.1 Cargo pumps for the purpose of filling or emptying the cargo tanks are to be used exclusively for this purpose, except that they may be used for crude oil washing , cargo pump room drainage (see 5.3.2.1 of this Chapter) and filling or emptying water ballast in the cargo tanks. They are not to have any connections to compartments outside the range of cargo tanks.

5.2.2.2 Cargo pumps are to be installed in isolated pump rooms.

5.2.2.3 Where cargo pumps are driven by steam engines or turbines having a steam temperature not exceeding 220℃, the prime movers may be installed in the pump room.

5.2.2.4 Where cargo pumps are driven by shafting which passes through a pump room bulkhead or deck, gastight glands are to be fitted to the shaft at the pump room plating. the glands are to be efficiently lubricated from outside pump room and are to be so designed as to prevent overheating. The seal parts of the glands are to be of materials that will not initiate sparks. Where a bellows piece is incorporated in the design, it is to be hydraulically tested to 0.34 MPa before fitting.

5.2.2.5 Cargo pumps installed in cargo pump rooms and driven by shafts passing through pump room bulkheads are to be fitted with temperature sensing devices for bulkhead shaft glands and shaft bearings of cargo pumps from outside of pump room. Alarm is to be initiated for excessive temperature of the above-mentioned glands and bearings.

5.2.2.6 All pumps which are capable of developing a pressure exceeding the design pressure of the system are to be provided with relief valves. Each relief valve is to be so arranged as to discharge back to the suction side of the pump, and to effectively limit the pump discharge pressure to the design pressure of the system.

5.2.2.7 Cargo oil pumps are to be capable of being stopped from a suitable position outside the pump room, as well as at the pumps.

5.2.2.8 A pressure gauge indicating the discharge pressure is to be fitted at the delivery side of each cargo oil pump. An additional gauge is to be fitted in the vicinity of the pump control station.

5.2.2.9 The safety requirements for stripping pumps fitted onboard and their piping systems are to be the same as those to cargo oil pumps and their piping systems.

5.2.2.10 Any integral hydraulic and/or electrical system used to drive both cargo and ballast pumps (integral cargo and ballast system) is to comply with the relevant provisions in 2.6.7, Chapter 2, PART FOUR of the Rules.

5.2.3 *Cargo piping system*

5.2.3.1 Cargo oil pipes are to be laid only within the cargo tank area, except for the bow or stern loading and unloading equipment outside cargo tank specified in the following 5.2.3.12.

5.2.3.2 Unless stated otherwise, cargo oil pipes are to be fully independent of other pipes.

5.2.3.3 Where Cargo tanks and slop tanks are provided with direct filling connections, the loading pipes are to be led to as low a level as practicable inside the tanks, so as to minimize the generation of static electricity.

5.2.3.4 Where it is necessary to fill the oil tanks by using the cargo oil suction pipes, a by-pass is to be provided to connect the suction and discharge ends of cargo oil pump. A stop valve is to be fitted on the by-pass.

5.2.3.5 Where the cargo oil piping system is used also as a ballast system for the cargo tanks, a blank flange or a removable spool piece is to be fitted between the sea chest valve and the cargo oil main, and a shut-off valve is to be fitted on each side of the blank flange or the removable spool piece.

The discharge of oily ballast water is to comply with the requirements for the prevention of pollution from ships.

5.2.3.6 Terminal pipes, valves and other fittings in the cargo loading and discharging lines to which shore installation hoses are directly connected, are to be of steel or ductile material. They are to be of robust construction and strongly supported.

A manually operated shut-off valve is to be fitted to each shore loading/discharging connection.

5.2.3.7 Expansion joints or bends are to be provided, where necessary, in the cargo pipelines.

5.2.3.8 For cargo piping system, means are to be provided to enable the contents of the cargo lines and pumps to be drained to a cargo tank or slop tank or to the shore facilities.

5.2.3.9 The operating rods for cargo valves in cargo tanks are to be extended to positions above the open deck. In the case of cargo tanks which are located adjacent to below-deck pump rooms or pipe tunnels, the operating rods may be located in these spaces at the bulkhead.

Stuffing boxes are to be fitted where the operating rod passes through the deck or bulkhead and to be so constructed that packing may be renewed from outside the cargo tanks. Indicators are to be provided at the operating hand wheels to show whether the valves are open or closed.

5.2.3.10 Materials used for the friction parts of the valves and operating rods of the cargo oil piping and of flexible couplings in shafts between the cargo pumps and the prime movers are to be such as to preclude the possibility of sparking while in operation.

5.2.3.11 Cargo oil pipelines are not to pass through ballast tanks. Where this can not be avoided, the pipes passing through ballast tanks are to have a wall thickness in accordance with the requirements in Table 5.3.4.2 of this Chapter and are to be provided with welded joints.

5.2.3.12 Bow or stern loading and unloading

Where bow or stern loading and unloading connections are provided outside cargo tank area, the arrangements are to be as follows:

(1) Cargo lines for bow or stern loading and unloading are to be installed outside accommodation spaces, service spaces, machinery spaces and control stations, and are to be clearly identified.

(2) Pipe joints outside the cargo area and used for bow or stern loading and unloading are to be welded.

(3) A spectacle flange or a removable spool piece is to be fitted at the connection line between the cargo loading and unloading line and cargo main line in cargo area, and a shut-off valve is to be fitted on each side of the blank flange or the removable spool piece.

(4) The loading and unloading connection is to be fitted with a shut-off valve and a blank flange. Spill containment is to be provided under the loading and unloading manifold.

(5) Arrangements are to be provided for cargo lines outside of the cargo area for easy draining to a slop tank or cargo tank.

(6) Space within 3 m from the oil spill containment boundary and connection mentioned in (4) above is considered to be gas hazardous area and is to be clearly identified.

(7) Fixed deck foam fire-extinguishing system required for cargo area is to effectively protect bow or stern loading and unloading area.

5.2.4 *Remote control valves*

5.2.4.1 Valves on deck and in pump rooms which are provided with remote control are to have local manual operating devices independent of the remote operating mechanism or emergency means for operating the valve actuators in the event of damage to the main hydraulic circuits on deck, such as connections, with isolating valves, fitted to the pipes near the valve actuators as far as possible for coupling to a standby portable pump carried on board.

5.2.4.2 Where the valves and their actuators are located inside the cargo tanks, two separate suctions are to be provided in each tank, or alternative means of emptying the tanks in the event of a defective actuator, are to be provided.

It is recommended that the lines to the valve actuators be led vertically inside the tanks from deck, and that connections, with isolating valves, be provided on deck lines for coupling to a standby portable pump carried on board for emergency operation of the valves in the event of damage to the main hydraulic circuits on deck.

5.2.4.3 Indication is to be provided at the remote control stations showing whether the valve is open or shut.

5.2.4.4 All actuators are to be of a type which will prevent the valves from opening inadvertently in the event of the loss of pressure in the operating medium. The design of the actuators is to be such that contamination of the operating medium with cargo oil cannot take place under normal operating conditions.

5.2.4.5 Compressed air is not to be used for operating actuators inside cargo tanks.

5.2.4.6 For the actuators in cargo tank, the supply tank is to be located as high as practicable above the level of the top of cargo tank, and all actuator supply lines are to enter the cargo tanks through the highest part of the tanks. Furthermore, the supply tank is to be of the closed type with an air pipe led to a safe space on the deck and fitted with a flameproof wire gauze diaphragm at its open end. This tank is also to be fitted with high and low level audible and visual alarms.

Section 3 BILGE, BALLAST AND OTHER PIPING SYSTEMS

5.3.1 *Pumping arrangements at ends of ship outside ranges of cargo tanks*

5.3.1.1 The pumping arrangements in machinery spaces and the forward end of the ship are to comply with the requirements for general cargo ships, unless otherwise specified in this Section.

5.3.1.2 The internal diameter d_1 of the bilge main and direct bilge suction in machinery spaces is to be calculated according to the requirements of 3.4.3.1 of this PART. L in the formula may be the ship's length reduced by the combined length of the cargo area. In such cases, the cross sectional area of the main bilge line is not to be less than twice the required cross sectional area of the engine room branch bilge lines.

5.3.1.3 The internal diameter d_2 of branch bilge suction pipes of machinery spaces is to be in accordance with the requirements in 3.4.3.3 of this PART.

5.3.1.4 Bilge, ballast and oil fuel lines, which are connected to pumps, tanks or compartments at the ends of the ship, are not to pass through cargo tanks or have any connections to cargo tanks or cargo lines, in general, no objection will be made to these lines being led through ballast tanks or void spaces within the range of the cargo tanks.

5.3.1.5 The arrangement of all pumps serving tanks directly adjacent to cargo tanks is also to comply with the requirements to cargo oil pumps in 5.2.2.2 to 5.2.2.5 of this Chapter, except for pumps and pipes serving fuel oil tanks located behind cargo tanks and directly adjacent to cargo tanks. Pumps and pipings serving above-mentioned fuel oil tanks may be located in engine room.

5.3.1.6 Unless specified otherwise, the piping system outside cargo area is to be mutual independent from the piping system within cargo area.

5.3.2 *Cargo pump room drainage*

5.3.2.1 Provision is to be made for the drainage of the cargo pump rooms by pump or bilge ejector suctions. Where cargo pumps or cargo stripping pumps are used for this purpose, the bilge suctions are to be fitted with screw-down non-return valves and, in addition, a stop valve is to be fitted on the pump connection to the bilge valve chest.

5.3.2.2 Cargo pump room suctions are not to enter machinery spaces.

5.3.2.3 The bilge drainage of the cargo pump rooms is to comply with the relevant requirements for the prevention of pollution from ships. It is recommended that cargo pump room bilge is to be drained into the slop tanks.

5.3.2.4 All the cargo pump rooms are to be provided with bilge level monitoring devices and suitable synchronous alarm devices.

5.3.3 *Cofferdam drainage within the ranges of cargo tanks*

5.3.3.1 The bilge suction equipment of cofferdam is to be installed within the ranges of cargo tanks. The requirements of 5.3.2.1 of this Section are to be complied with, where cargo pumps or cargo stripping pumps are used for drainage. Alternatively, cofferdams may be drained by bilge ejectors.

5.3.4 *Ballast piping within the range of the cargo tanks*

5.3.4.1 Ballast tanks within the range of cargo tanks and ballast pipelines in the double bottom tank are to be provided with separate ballast pumps and pipelines. The ballast pump is to be located in the cargo pump room or other suitable space within the range of the cargo tanks. The arrangement of ballast pumps is also to comply with the requirements for cargo oil pumps in 5.2.2.2 to 5.2.2.5 of this Chapter. However, If ballast pump is located in individual ballast pump tank, the requirements of 5.2.2.5 may be exempted.

5.3.4.2 The ballast lines are not to pass through cargo tanks. Where this cannot be avoided, the ballast lines passing through cargo tanks are to be heavy gauge steel, having welded or heavy flanged joints. The pipes in cargo tanks are not to be less than the value given in Table 5.3.4.2 in thickness. The number of joints is to be kept to a minimum. Where it is proposed to use material which is more resistant to corrosion than carbon steel, the pipe thickness may be suitably reduced.

Pipe thickness inside cargo tanks *Table 5.3.4.2*

Nominal diameter of pipe① (mm)	Minimum wall thickness (mm)
50	6.3
100	8.6
125	9.5
150	11.0
200 and above	12.5

Note: ① For nominal diameter with the value between those listed in the Table, the corresponding pipe thickness may be

calculated by insertion.

5.3.4.3 Expansion bends or bellows, not glands, are to be fitted to the ballast pipes in the cargo tanks.

5.3.4.4 For clean ballast piping, provision may be made for emergency discharge of water ballast by means of a portable spool connection to cargo oil pump and where this is arranged, a screw-down non-return valve is to be fitted in the ballast suction to the cargo oil pump and a screw-down valve is to be fitted to the cargo oil lines.

5.3.4.5 Where the clean ballast pumps are installed in a cargo pump room, the sea inlets of these pumps are to be entirely separated from the sea inlets of the cargo pumps.

5.3.4.6 Water supply of fire main may be used as dynamic water of eductors for discharging ballast water of ballast tank or for discharging bilge water of cofferdam in cargo area, and the following requirements are to be complied with:

(1) eductors are to be located in cargo area such as pump tank;

(2) water supply pipes from fire main for the above-mentioned purpose are to be led from upper deck in cargo hold area;

(3) a stop-check valve is to be fitted at appropriate position near deck before the water supply pipe passes through deck.

5.3.5 *Air and sounding pipes for cofferdams*

5.3.5.1 Deep cofferdams at the fore and aft ends of the cargo spaces and other tanks or cofferdams within the range of the cargo tanks, which are not intended for cargo, are to be provided with air and sounding pipes led to the open deck. The air pipes are to be fitted with renewable wire gauze diaphragms at their outlets. The height of air pipes from the deck to the point where water may have access below is not to be less than 760 mm.

5.3.5.2 So far as practicable, the air and sounding pipes required in 5.3.5.1 are not to pass through cargo tanks. Were side ballast tank or empty side tank are not provided on ship, the air and sounding pipes in way of the double bottom may pass through cargo tanks. But a wall thickness of the pipes passing through cargo tanks are to comply with the requirements in Table 5.3.4.2 of this Chapter and the pipes are to be completion or with welded joints.

5.3.6 *Location and separation of spaces in combination carriers*

5.3.6.1 The slop tanks are to be surrounded by cofferdams except where the boundaries of the slop tanks where slop may be carried on dry cargo voyages are the hull, main cargo deck, cargo pump-room bulkhead or fuel oil tank. These cofferdams are not to be open to a double bottom, pipe tunnel, pump-room or other enclosed space. Means are to be provided for filling the cofferdams with water and for draining them.

5.3.6.2 Means are to be provided for isolating the piping connecting the pump-room with the slop tanks referred to in 5.3.6.1. The means of isolation are to consist of a valve followed by a spectacle flange or a spool piece with appropriate blank flanges. This arrangement is to be located adjacent to the slop tanks, but where this is unreasonable or impracticable it may be located within the pump-room directly after the piping penetrates the bulkhead. A separate pumping and piping arrangement is to be provided for discharging the contents of the slop tanks directly over the open deck when the ship is in the dry cargo mode.

5.3.6.3 Hatches and tank cleaning openings to slop tanks are only permitted on the open deck and are to be fitted with closing arrangements. Except where they consist of bolted plates with bolts at watertight spacing, these closing arrangements are to be provided with locking arrangements which are to be under the control of the responsible ship's officer.

5.3.6.4 Where cargo wing tanks are provided, cargo oil lines below deck are to be installed inside these tanks. Where cargo wing tanks are not provided, cargo oil lines below deck are to be placed in special ducts which are capable of being adequately cleaned and ventilated.

Section 4 CARGO OIL HEATING

5.4.1 *General requirements*

5.4.1.1 The medium used for heating cargo oil is to have a temperature not exceeding 220℃.

5.4.2 *Steam heating*

5.4.2.1 The steam used for heating cargo oil is to be of saturated steam.

5.4.2.2 An observation tank is to be provided for the heating coil drains and is to be located in a well ventilated and well illuminated part of the machinery space remote from the boilers, diesel engine exhaust

pipes and electrical equipment. The upper drain pipe of the tank is to be led to a sludge tank.
5.4.2.3 The heating steam supply and return lines are not to penetrate the cargo tank plating, other than at the top of the tank, and these lines are to be run above the weather deck.
5.4.2.4 Isolating shut-off valves or cocks are to be provided at the inlet and outlet connections to the heating circuit(s) of each tank. The heating coil exhaust pipes of the cargo oil heating systems for each tank are to be fitted with inspection valves or cocks on the open deck to check the heating coils for leakage.
5.4.2.5 Spectacle flanges or spool pipes are to be provided in the heating steam supply and return pipes to the cargo heating system, at a suitable position within the cargo area, so that the lines can be blanked off in circumstances where the cargo does not require to be heated or where the heating coils have been removed from the tanks. Alternatively, blanking arrangements may be provided for each tank heating circuit.

5.4.3 *Thermal oil heating*
5.4.3.1 Thermal oil heating of cargo oil is to comply with the relevant requirements of Section 8, Chapter 4 of this PART.
5.4.3.2 The heating oil supply and return lines are not to penetrate the cargo tank plating, other than at the top of the tank.
5.4.3.3 Isolating shut-off valves are to be provided at the inlet and outlet connections to the heating oil circuit(s) of each tank.
5.4.3.4 Spectacle flanges or spool pipes are to be provided in the heating oil supply and return pipes to the cargo heating system, at a suitable position within the cargo area, so that the lines can be blanked off in circumstances where the cargo does not require to be heated or where the heating coils have been removed from the tanks.

Section 5 CARGO TANK LEVEL SOUNDING

5.5.1 *General requirements*
5.5.1.1 Each cargo tank is to be fitted with suitable means for ascertaining the liquid level, and the requirements respectively in 5.5.2 to 5.5.4 below are to be complied with.

5.5.2 *Closed sounding devices*
5.5.2.1 In oil tankers fitted with a fixed inert gas system, the cargo tanks are to be fitted with closed sounding devices which do not permit the escape of cargo to the atmosphere when being used.

5.5.3 *Limited sounding devices*
5.5.3.1 Sounding pipes or other approved devices, which may permit a limited amount of vapor to escape to atmosphere when being used, would be accepted for those tanks which are not required to be fitted with closed sounding devices. The devices are to be so designed as to minimize the sudden release of vapor or liquid under pressure and the possibility of liquid spillage on deck. Means are also to be provided for relieving tank pressure before the device is operated.
Arrangements which permit the escape of vapor to the atmosphere are not to be fitted in enclosed spaces.

5.5.4 *Open sounding devices*
5.5.4.1 Separate ullage openings may be fitted as a reserve means for sounding cargo tanks.

Section 6 CARGO TANK VENTING ARRANGEMENTS

5.6.1 *General requirements*
5.6.1.1 Each cargo tank is to be fitted with venting arrangements which will limit the pressure or vacuum in the tanks. Vent pipes of cargo tanks are not to be in connection with the air pipes led from other tanks. Cargo tank venting arrangements are to be designed to provide:
(1) venting of large volumes of vapor/air mixtures during cargo handling and gas freeing operation;
(2) pressure/vacuum release of small volumes of vapor/air mixtures flowing during a normal voyage due to the change of temperature;
(3) a secondary means of allowing full flow relief of vapors, air or inert gas mixtures is to be provided in the event of failure of the arrangements in (1). The secondary means are to be capable of preventing over-pressure or under-pressure in the event of damage to, or inadvertent closing of, the means of isolation

required in the paragraph 5.6.2.2 of the Section. Alternatively, pressure sensors may be fitted in each tank protected by the arrangement required in 5.6.1.1 (1), with a monitoring system in the ship's cargo control room or the position from which cargo operations are normally carried out. Such monitoring equipment is also to provide an alarm facility which is activated by detection of over-pressure or under-pressure conditions within a tank.

5.6.2 *Pressure/vacuum and venting systems*

5.6.2.1 The pressure/vacuum system and venting system may be separate or combined and may be connected to an inert gas system.

5.6.2.2 The vent and/or pressure/vacuum valve stand pipes are to be connected to the highest part of each tank, and where combined systems are adopted, a means of isolation is to be provided between each tank and a common main. Any means of isolation must continue to permit the flow caused by thermal variations in a cargo tank in accordance with the provisions of 5.6.1.1(2). If cargo loading and ballasting or discharging of a cargo tank or cargo tank group is intended, which is isolated from a common venting system, that cargo tank or cargo tank group are to be fitted with a means for over-pressure or under-pressure protection as required in 5.6.1.1(3) of this Section. Any isolation is also to continue to permit the passage of large volumes of vapour, air or inert gas mixtures during cargo loading and ballasting, or during discharging.

5.6.2.3 In no case are shut-off valves to be fitted either above or in the pipe leading to a pressure/vacuum valves. However, by-pass valves may be fitted or provision may be made to enable the tank pressure/vacuum valves to be held in an open position. The arrangements are to be such that clear indication is given when the by-pass valve is open or the pressure/vacuum valve is secured in the open position.

5.6.2.4 The pressure/vacuum valve is to be located on open deck and means are to be provided to enable the functioning of the valve to be easily checked.

5.6.2.5 Pressure/vacuum valves are to be capable of preventing the cargo tanks from sustaining a positive pressure (generally not more than 0.021 MPa) which is greater than the testing pressure, and a negative pressure of less than 0.007 MPa.

5.6.2.6 The area of the venting system used during cargo loading is to be based on the maximum design loading rate and a gas evolution factor of 1.25.

5.6.2.7 Suitable drainage arrangements are to be provided in the vapor lines where condensate might collect.

5.6.3 *Arrangement of vapor outlets*

5.6.3.1 Outlets from vent pipes and, where necessary, outlets/inlets from pressure/vacuum valves are to be provided with readily renewable wire gauze①. Material of wire gauze is to be resistant to corrosion.

5.6.3.2 Vent outlets and pressure/vacuum valve, if used during loading, are to be arranged to discharge the vapor in an upward vertical direction. Vent outlets and pressure/vacuum valve inlets and outlets are to be arranged to prevent the entrance of water into the cargo tanks.

5.6.4 *Height and location of cargo tank vent outlets*

5.6.4.1 Vent outlets for cargo loading, discharging and ballasting required in 5.6.1.1(1) of this Section are to:

(1) permit the free flow of vapor mixtures; or

(2) permit the throttling of the discharge of the vapor mixtures to achieve a velocity of not less than 30 m/s. They are also to be so arranged that the vapor mixture is discharged vertically upwards.

Where the method is by free flow of vapor mixtures, the arrangement is to be such that the outlet is not to be less than 6 m above the cargo tank deck or fore and aft gangway if situated within 4 m of the gangway and located not less than 10 m measured horizontally from the nearest air intakes and openings to enclosed spaces containing a source of ignition and from deck machinery and equipment which may constitute an ignition hazard.

Where the method is by high-velocity discharge, the outlets are to be located at a height not less than 2 m above the cargo tank deck and not less than 10 m measured horizontally from the nearest air intakes and openings to enclosed spaces containing a source of ignition and from deck machinery and equipment which may constitute an ignition hazard.

---

① Refer to MSC/Circ.677 – Revised Standards for the Design, Testing and Locating of Devices to Prevent the Passage of Flame into Cargo Tanks in Tankers and MSC/Circ.450/Rev.1 – Revised Factors to be Taken into Consideration when Designing Cargo Tank Venting and Gas Freeing Arrangements.

5.6.4.2 Openings for pressure release required in 5.6.1.1(2) of this Section are to be arranged in accordance with 5.6.4.1 of this Section.

5.6.5 *Preventive measures against liquid rising in the venting system*

5.6.5.1 Provisions are to be made to guard against liquid rising in the venting system to a height which would exceed the design head of cargo tanks. This may be accomplished by high-level alarms or overflow control systems or other equivalent means, together with independent gauging devices and cargo tank filling procedures. For the purposes of this regulation, spill valves are not considered equivalent to an overflow system.

Section 7 REQUIREMENTS FOR DOUBLE HULL SPACES OF OIL TANKERS

5.7.1 *Inerting, ventilation and gas measurement of double hull spaces*

5.7.1.1 Double hull spaces are to be provided with suitable ventilation connections.

5.7.1.2 On tankers required to be fitted with inert gas systems:

(1) double hull spaces are to be fitted with suitable connections for the supply of inert gas;

(2) where such spaces are connected to an inert gas distribution system, means is to be provided to prevent flammable gases from the cargo tanks entering the double hull spaces through the system;

(3) where such are not connected to an inert gas distribution system, appropriate means is to be provided to allow connection to the inert gas main.

5.7.1.3 Tankers are to be provided with suitable portable instruments for measuring oxygen and flammable vapor concentrations. In selecting these instruments, due attention is to be given for their use in combination with the gas sampling systems referred to in 5.7.1.4 of this Section.

5.7.1.4 Where atmosphere in double hull spaces cannot be reliably measured using flexible gas sampling hoses, such spaces are to be fitted with permanent gas sampling lines. The configuration of such line systems is to be adapted to the design of such spaces.

5.7.1.5 The materials of construction and the dimensions of gas sampling lines are to be such as to prevent restriction. Where plastic materials are used, they are to be electrically conductive.

Section 8 REQUIREMENTS FOR OIL TANKERS INTENDED FOR CARRIAGE OF CARGO OIL HAVING A FLASH POINT EXCEEDING 60℃

5.8.1 *General requirements*

5.8.1.1 For oil tankers intended for the carriage of cargo oil having a flash point above 60℃ (closed cup test) and where the maximum temperature heated for the cargo oil in cargo oil tanks is at least 10℃ below the flash point of the cargo oil, the requirements of this Chapter are to be complied with, but the following in this Chapter may not be applicable:

5.1.2, 5.1.4, 5.1.6, 5.1.8, 5.2.2.1 to 5.2.2.5, 5.2.3.1, 5.2.3.12, 5.2.4.5, 5.3.1.5, 5.3.3.1, 5.3.4.1, 5.3.4.6, 5.5.2.1, 5.6.1 to 5.6.5 and 5.7.1.

5.8.2 *Vent pipes of cargo tanks*

5.8.2.1 Vent pipes are to be led from the highest part of the tank to the open area above the freeboard deck and such pipes are not to be connected to those of other than cargo oil tank spaces.

5.8.2.2 Vent pipes required in 5.8.2.1 of this Section may be fitted for each cargo oil tank, vent pipes required for several cargo oil tanks may also be led to a common main, but it is proposed that a pressure/vacuum valves is to be fitted on the common main.

5.8.2.3 The height of the outlet ends of vent pipes (including branch and main) are not to be less than 760 mm above the freeboard deck.

5.8.2.4 The outlet ends of vent pipes are to be provided with a wire gauze diaphragm of corrosion-resistant material which can be readily removed for renewal.

CHAPTER 6 BOILERS AND PRESSURE VESSELS

Section 1 GENERAL PROVISIONS

6.1.1 *General requirements*

6.1.1.1 The requirements of this Chapter apply to the following devices or equipment of welded construction:

(1) boilers generating steam with a pressure above atmospheric pressure (0.103 MPa) or heating pressurized hot water above 120℃;

(2) thermal oil heaters;

(3) pressure vessels.

6.1.1.2 The certification requirements and product survey of boilers and pressure vessels are to comply with the relevant requirements in Chapter 3, PART ONE of the Rules.

6.1.2 *Classification*

6.1.2.1 For the purpose of the Rules, boilers and pressure vessels are classified in accordance with the design pressure p (MPa), thickness δ (mm) of cylindrical shell, working temperature t (℃) of cylindrical shell and inner diameter d (mm) of pressure vessel, see Table 6.1.2.1.

Classes of Boilers and Pressure Vessels *Table 6.1.2.1*

Type \ Class	Class I	Class II	Class III
Boilers or thermal oil heaters	$p > 0.35$	$p \leq 0.35$	–
Steam generators	$p > 1.15$, or $p.d > 1500$	Steam generators other than Class I	–
Pressure vessels or heat exchangers	$p > 4$, or $\delta > 40$, or $t > 350$	$4 \geq p > 1.57$, or $40 \geq \delta > 16$, or $350 \geq t > 150$	Pressure vessels and heat exchangers other than Classes I and II
Pressure vessels or heat exchangers for liquefied gases, toxic and corrosive substances	All	–	–

6.1.2.2 The small auxiliary boilers mentioned in this Chapter are the boilers having an evaporating capacity not exceeding 1,000 kg per hour and a design pressure not exceeding 0.78 MPa.

6.1.3 *Definitions*

6.1.3.1 For the purpose of this Chapter:

(1) Design pressure

The design pressure is the maximum permissible working pressure for boilers and pressure vessels. Strength calculations for boilers and pressure vessels are to be based on the design pressure and not to be less than the highest set pressure of safety valve.

The design pressure of economizers is the maximum working pressure of the medium in the economizer.

(2) Metal temperature

The metal temperature is to be taken as the actual metal temperature expected under operating conditions for the pressure part concerned, and is to be stated in the relevant plans of design.

(3) Boilers

Boilers include all closed vessels together with their fittings which receive the thermal energy released by burning fuel or any other thermal energy for the generation of steam or hot water.

(4) Pressure vessels

Pressure vessels are vessels together with their fittings which are subjected to an external or internal pressure.

(5) Heat exchangers

Heat exchangers are devices together with their fittings which are used for heat exchange between two or more media. Heat exchangers and their fittings are to be designed, manufactured and inspected in accordance with the requirements for pressure vessels.

(6) Steam generators

Steam generators are heat exchangers together with their fittings which are used to generate steam. Unless stated otherwise, the requirements for boilers in this Chapter apply to steam generators.

(7) Thermal oil heaters

Thermal oil heaters are devices in which thermal oil is heated and circulated.

6.1.4 *Plans and documents*

6.1.4.1 The following plans and documents of boilers are to be submitted for approval:
(1) General arrangement (the highest part of heating surfaces of the boiler is to be clearly indicated in the submitted drawing);
(2) Body construction (including details of welded connections, attachments and supports);
(3) Construction of pressure parts (cylindrical shell, steam and water drums, headers, combustion chamber, furnace, superheater, desuperheater, economizer, etc.);
(4) Arrangement of mountings and fittings;
(5) Safety valves with diameter calculation;
(6) Strength calculations;
(7) Heat treatment procedures of welded connections;
(8) Test pressure.

6.1.4.2 The following plans and documents of pressure vessels are to be submitted for approval:
(1) General arrangement;
(2) Body construction (including details of welded connections, attachments and supports);
(3) Construction of pressure parts (cylindrical shell, end plate, etc.);
(4) Arrangement of mountings and fittings;
(5) Strength calculations;
(6) Test pressure.

6.1.4.3 For thermal oil heaters, the following plans and information are to be submitted for approval or reference, in addition to those as required for boilers:
(1) Plan of monitoring and alarm system;
(2) Plan of fire-extinguishing system and relevant calculations (if applicable);
(3) Design temperature and pressure of the system, physical and chemical properties (e.g. viscosity, flash point, ignition temperature, decomposition temperature, self-ignition temperature) of thermal oil (for reference);
(4) Operation and maintenance instructions (for reference).

Section 2 DESIGN AND MANUFACTURE

6.2.1 *Design*

6.2.1.1 The design of boilers and pressure vessels is to comply with the relevant requirements in Appendix 1 to Appendix 6 of this Chapter. All the designs are to be submitted for approval prior to construction.

6.2.1.2 The metal temperature of boiler parts is, in any case, not to be less than the value given in Table 6.2.1.2, nor less than 250℃. The metal temperature of the pressure vessel parts in direct contact with hot medium is to be taken as the highest working temperature of the medium.

Metal temperature of boiler parts *Table 6.2.1.2*

Components \ Working condition	Not heated	Heated but well insulated	Subject to convective heat	Subject to radiant heat
Steam or water drum, header	t	t + 10℃	t + 50℃	–
Superheater cylinder or header	t + 15℃	t + 30℃	t + 50℃	–
Boiler generating tube	–	–	t + 25℃	t + 50℃
Superheater pipe	–	–	t + 35℃	t + 50℃
Economizer pipe	–	–	t + 30℃	–
Furnace, smoke duct and back tube sheet in dry back combustion chamber	–	–	–	t + 90℃
Wet back combustion chamber	–	–	–	t + 50℃

Note: t — working medium temperature, (℃).

6.2.1.3 Boilers are to be adequately insulated. The insulation is to have a metallic sheathing. When the boiler is under working conditions, the temperature of the sheathing is generally not to exceed 60℃.

6.2.1.4 Every shell type economizer is to be provided with removable lagging at the circumference of the tube end plates to enable ultrasonic examination of the tube plate to shell connection.

6.2.2 *Materials*

6.2.2.1 The materials used in the construction of boilers and pressure vessels are to be in compliance with the relevant provisions contained in ISC Rules for Materials and Welding. Where it is proposed to use materials other than those specified in the aforesaid, details of the mechanical properties (including mechanical property values used for the calculation of allowable stresses), chemical compositions and heat treatment are to be submitted for approval.

6.2.3 *Plate cutting*

6.2.3.1 Plates are to be cut to size and shaped by machine flame cutting and/or machining. Where the plate thickness does not exceed 25 mm, cold shearing may be used provided that the sheared edge is cut back by machining or chipping for a distance of 1/4 of the plate thickness, but in no case by less than 3 mm. After being cut and before further work is carried out upon them, all plate edges are to be examined for laminations and cracks.

6.2.4 *Forming*

6.2.4.1 Plates for shell sections and end plates are, so far as possible, to be hot and cold formed by machine. Forming by hammering is not to be employed. Forming is not to impair the quality of the material regardless of heating or not.

6.2.4.2 After forming, both shell plates and end plates are to be suitably heat treated. This heat treatment may be held concurrently with post-weld heat treatment.

6.2.5 *Allowable stress*

6.2.5.1 The allowable stress of boiler and pressure vessel parts is to be determined by the following formulae, and the lower value is to be taken:

(1) Metal temperature equal to or less than 50℃:

$[\sigma] = R_m/2.7$; $[\sigma] = R_{eH}/1.5$

(2) Metal temperature more than 50℃:

$[\sigma] = R_m/2.7$; $[\sigma] = R^T_{eH}/1.5$; $[\sigma] = R^T_{m100000}/1.5$

(3) Pressure vessels for stowage of liquid gas:

$[\sigma] = R_m/3.0$; $[\sigma] = R_{eH}/2.0$

where: R_m — specified tensile strength of material at room temperature, in N/mm^2;

R_{eH} — specified yield stress of material at room temperature, in N/mm^2;

R^T_{eH} — specified yield stress or proof stress of material at metal temperature, in N/mm^2;

$R^T_{m100000}$ — average stress to produce rupture in 10^5 h of material at metal temperature, in N/mm^2. In general, it is to be selected according to the relevant requirements of ISC Rules for Materials and Welding when the metal temperature is more than 350℃.

The allowable stress for steel castings is to be taken as 80% of the value determined by the method indicated above, using the appropriate value for cast steel.

6.2.6 *Joint factor of welded seam*

6.2.6.1 For welded seams welded on both side or on one side with a sealing run, the strength factor φ' used in the equations in this Chapter is given in Table 6.2.6.1 based on the method of examination employed.

Strength factor φ' of welded seam **Table 6.2.6.1**

Class	Strength factor of welded seam	Perspective inspection	Conventional welded seam test plate	Heat treatment
I	1	To be done, see Rules for Materials and Welding	To be done	See Rules for Materials and Welding
II	0.85	To be done, see Rules for Materials and Welding	To be done	See Rules for Materials and Welding
III	0.60	–	–	–

6.2.6.2 For boilers of Class II and pressure vessels of Classes II and III where higher joint factor of welded seam than that required for the respective class is selected, the welded seams are to be examined in accordance with the requirements for the higher joint factor of welded seam.

6.2.7 *Welding and heat treatment*

6.2.7.1 The welding, welds examination and post-welding heat treatment of all pressure parts of boilers and pressure vessels are to comply with the requirements of ISC Rules for Materials and Welding.

6.2.7.2 Cold-formed cylindrical shells of boilers and pressure vessels are to be subject to stress relief heat treatment, which may be carried out together with the post-welding heat treatment. For cylindrical shell having an inner diameter greater than or equal to 20 times the thickness of shell plate, the heat treatment may be dispensed with.

6.2.7.3 Hot formed parts of boilers or pressure vessels are to be normalized provided that hot forming is not carried out at a temperature within the normalizing range. Parts made of alloy steel are, in addition, to be tempered as necessary.

6.2.8 *Pads*

6.2.8.1 The pads for securing the mountings and fittings to boilers and pressure vessels are to be of sufficient thickness to permit the studs being screwed into them with a length not less than the diameter of the studs without penetrating the pads. The pads and cylindrical shell are to be tightly fitted.

6.2.9 *Access arrangements*

6.2.9.1 Boilers and pressure vessels are to be provided with manholes to facilitate internal examination and cleaning of the cylindrical shell and steam or water drums. In the case of boiler components and pressure vessels such as cylindrical shells, headers, which are too small to permit entry, sufficient number of sight holes for these purposes is to be provided.

Manholes in cylindrical shells are preferably to have their minor axes arranged longitudinally.

6.2.9.2 Doors for manholes and sight holes are to be made of steel plate or steel forgings. Doors of the internal type are to be provided with spigots which have a clearance of not more than 2 mm all round.

6.2.9.3 Holes of boilers and pressure vessels are in general to comply with the following:

(1) Boilers with an inside diameter of more than 1000 mm and vessels with an inside diameter of more than 800 mm are to be equipped at least with one manhole.

(2) In the case of boilers and their components (e.g. cylindrical shells, headers) which are too small to permit entry for internal examination and cleaning, and of pressure vessels on which no manhole is practicable, sufficient head holes or hand holes for these purposes are to be provided.

(3) Vessels with an inside diameter of up to 300 mm are not necessarily to be equipped with any inspection hole.

(4) The minimum dimensions of various holes are in general required as follows:

manholes: 300 × 400 mm (minimum diameter of 400 mm for circular ones);
head holes: 220 × 320 mm (minimum diameter of 320 mm for circular ones);
hand holes: 80 × 100 mm.

6.2.10 *Structure attachment*

6.2.10.1 Where cylindrical shell consists of shell plates and/or tube plates which differ in thickness, the shell plates and/or tube plates are to be so butt welded that their centerlines form a continuous circle (see Figure 6.2.10.1). At the welded joint, the thicker plate is to be reduced in thickness by machining to a taper for a distance not less than two times the difference in the thickness.

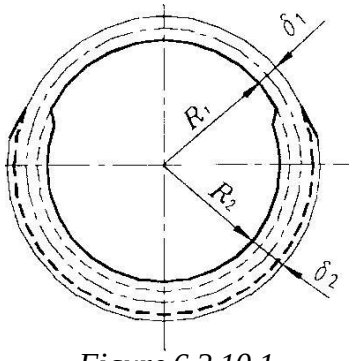

Figure 6.2.10.1

6.2.10.2 For the attachment of torispherical or ellipsoidal ends to cylindrical shells, see Figure 6.2.10.2. Where the difference in thickness is the same throughout the circumference, the thicker plate is to be reduced in thickness by machining to a taper for a distance not less than four times the offset, so that the

two plates are of equal thickness at the position of the circumferential weld. A parallel portion may be provided between the end of the taper and the weld edge preparation; alternatively, if so desired, the width of the weld may be included as part of the smooth taper of the thicker plate.

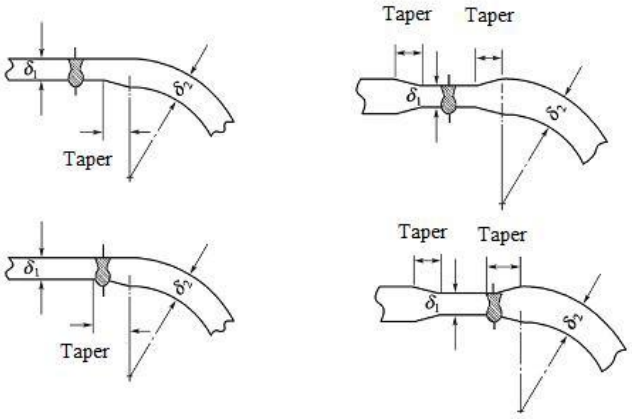

Figure 6.2.10.2

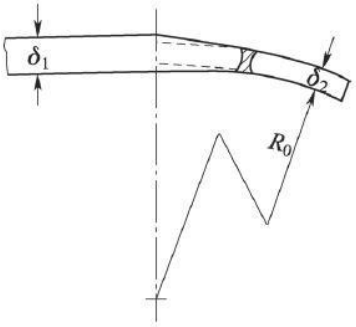
The thickness of the plates at the position of the circumferential weld is not to be less than that required for cylindrical shell of seamless or welded construction, whichever is applicable, of the same diameter and material.

6.2.10.3 Where hemispherical ends are butt welded to cylindrical shells, the thickness of the shell is to be tapered to that of the end, and the centre of the hemisphere is to be so located that the entire tapered portion of the shell and the butt weld are within the hemisphere, see Figure 6.2.10.3.



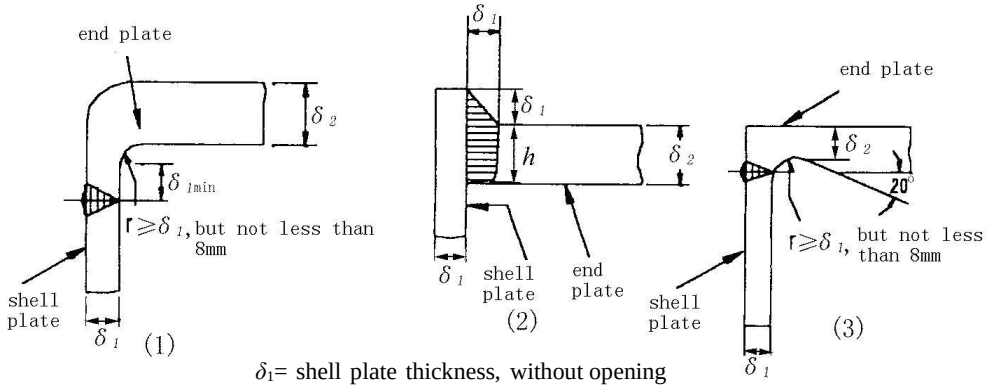


Figure 6.2.10.3

If the hemispherical end is provided with a parallel portion to be butt welded to the shell, the thickness of this portion is not to be less than that required for a seamless or welded shell.

6.2.10.4 The typical acceptable methods of attaching flat ends to cylindrical and rectangular headers are as shown in Figure 6.2.10.4.

δ_1= shell plate thickness, without opening weakening

δ_2= end plate thickness

$h = 2\delta_1$ or δ_2 -1.5mm, whichever is lesser

Figure 6.2.10.4

6.2.11 Fitting of tubes in water tube boilers

6.2.11.1 Where boiler tubes are expanded into the tube holes and are not normal to the tube plates, there is to be a neck having an effective depth h of not less than 13 mm (see Figure 6.2.11.1). Where the tubes are practically normal to their plates, this parallel seating is not to be less than 9.5 mm in depth.

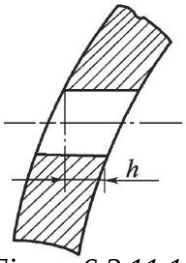

Figure 6.2.11.1

6.2.11.2 For tubes expanded into the tube holes in cylindrical shell or headers, they are to project through the neck or belt of parallel seating by at least 6 mm, but not more than 16 mm. Where the tube ends are secured from drawing out by means of bell mouthing, the included angle of belling is not to be less than 30°.

6.2.12 *Design and construction of exhaust heating shell type economizers*

6.2.12.1 Design and construction of shell type economizers are to pay particular attention to the welding, heat treatment and inspection arrangements at the tube plate connection to the shell.

6.2.13 *Prevention of soot accumulation*

6.2.13.1 Where the design (e.g. using boiler tubes with extended heat exchange surface) of exhaust gas boilers and economizers may lead to soot accumulation, resulting in fires or risks of excessive flow resistance, effective measures are to be taken to control soot accumulation, e.g. by fitting effective soot cleaning system, exhaust gas bypass, etc.

6.2.13.2 Unless specified otherwise by the flag States, the washing water generated during operation of the soot cleaning system is to be drained to appropriate tanks, and necessary measures are to be taken to prevent water from flowing into diesel engines.

Section 3 BOILER MOUNTINGS AND FITTINGS

6.3.1 *General requirements*

6.3.1.1 Boiler mountings are to be connected to pads or stand-pipes with flanges. Mountings under 20 mm in diameter may be fitted with screws on pads or stand-pipes.

Valves over 30 mm in diameter and the covers are to be secured by flange connections and valves having a diameter up to 30 mm and the covers may be secured by screw connections with stoppers.

6.3.1.2 Valve bodies for boilers are to be made of steel or other equivalent material. For boilers having a design pressure not exceeding 0.98 MPa and steam temperature not exceeding 220℃, the valve bodies may be made of cast iron with the exception of blow-off valves.

6.3.1.3 Boiler mountings are to be located in positions easily accessible for maintenance and operation.

6.3.2 *Feed check valves*

6.3.2.1 Each boiler is to be provided with two independent feed check valves. But for small vertical boilers and exhaust-gas boilers for non-essential service, one feed check valve may be accepted.

6.3.2.2 Each feed check valve is to consist of a screw-down valve and a non-return valve, the lift of non-return valve is to be adjustable. The screw-down valve is to be attached direct to the boiler. The non-return valve is to be adjacent to the screw-down valve wherever practicable. For boilers fitted with economizers, the screw-down valve may be attached direct to the economizer which forms an integral part of the boiler.

For water tube boilers, the feed check valves are to be fitted with efficient gearing, whereby they can be satisfactorily operated from the stoke hold floor or other convenient position.

6.3.2.3 For water tube boilers at least one of the feed water systems is to be fitted with an approved feed

water regulator whereby the water level in the boilers is controlled automatically.

6.3.3 *Feed standpipes and internal pipes*

6.3.3.1 For boilers having a design pressure more than 2.75 MPa, the standpipes for feed inlets are to be designed with an internal pipe with the object of minimizing thermal stresses where temperature differences occur between the feed pipe and boiler shell.

6.3.3.2 The internal pipes for feed inlets are to be so arranged that no feed water impinges directly on the inner surfaces of the boiler shell exposed to hot gases.

6.3.4 *Water level indicators*

6.3.4.1 Each boiler whose operation is designed at a specified water level is to be fitted with at least two water level indicators, one is to be a direct reading gauge glass, and the other may either be water gauge or other equivalent device (e.g. remote water level indicator).

6.3.4.2 The water gauges are to be readily accessible and so located that the water level is clearly visible. The lowest visible part of the glass water gauge is to be situated at the lowest safe working water level, but for water tube boilers, this level is to be situated at 50 mm below the lowest safe working water level.

In water tube boilers, where the steam and water drum exceeds 4 m in length and is fitted athwartships, one gauge glass is to be fitted in a suitable place at or near each end of the drum.

6.3.4.3 The water gauges are to be of flat glass type. Glass tube glass gauges with reliable protections may be used for boilers having a working pressure not exceeding 0.78 MPa.

Water gauge cocks are to be provided with operating gear if necessary and are to be so arranged that they can be easily operated without danger when the glass is damaged.

6.3.4.4 Water gauges are also to be provided with blow-off devices.

6.3.4.5 The water gauges may be fitted directly to the boiler shell or to columns, these columns are to be directly bolted or screwed to the boiler shells, or connected to the boiler by means of pipes. If they are connected by means of pipes, these pipes are to be fitted with cocks or screw-down valves with indicators showing whether the valves are open or shut. The internal diameter of the connecting pipes or columns is to be selected in accordance with Table 6.3.4.5.

Internal diameter of connecting pipes and columns *Table 6.3.4.5*

Internal dia. of boiler body (m)	Internal dia. of connecting pipes (mm)	Internal dia. of column (mm)
> 3	≥ 38	≥ 63
2.3~3	≥ 32	≥ 50
< 2.3	≥ 25	≥ 45

The connecting pipes which communicate with the steam space are to be so arranged that there is no pocket or bend where accumulation of condensate water can lodge. Connecting pipes are not to pass through the uptake; if, however, this requirement cannot be complied with, they may pass through the uptake by means of a pipe tunnel with at least 50 mm air gap clear of the pipe all round.

6.3.4.6 In general, the lowest water level in the boiler is to be as follows:

(1) For boilers with water tubes submerged when cold, the lowest water level is to be above the top row of tubes; for boilers with tubes not submerged when cold, the manufacturer is to submit the design information for the lowest level for consideration.

(2) The lowest water level in horizontal smoke tube boilers is not to be less than 75 mm above the top of combustion chambers or smoke tubes, but for multi-return flow smoke tube boilers, this level may be suitably lowered.

(3) The lowest water level in combined boilers is not to be less than 50 mm above the hot water tubes.

(4) The height of lowest water level in vertical boilers having vertical smoke tubes is not to be less than half the length of smoke tubes.

(5) The above mentioned heights of the lowest water level are to be still maintained when the ship has a list of 4°.

6.3.4.7 Water tube boilers serving turbine propulsion machinery are to be fitted with a high-water-level alarm.

6.3.4.8 Smoke tube exhaust gas boilers are to be provided with a low level alarm device and an exhaust gas bypass or a standby feed water pump. An alarm is to be given and exhaust gas automatically (or manually) bypassed or the standby feed water pump automatically started in a low water level condition.

6.3.4.9 Water tube exhaust boilers with forced circulation are to be provided with a low water flow or low pressure alarm device and a standby water circulating pump. An alarm is to be given and the standby water circulating pump automatically started in a low water flow or low pressure condition.

6.3.5 *Safety valves*

6.3.5.1 Boilers are to be fitted with not less than two safety valves. For small auxiliary boilers one safety valve may be accepted. For boilers with superheaters, at least one safety valve is to be fitted on the superheater.

Where a superheater is fitted as an integral part of a boiler, viz. there is no stop valve fitted between the superheater and the boiler, the area of superheater safety valve may be included in the total area of boiler safety valves; and where a stop valve is fitted between the superheater and the boiler, the area of superheater safety valve is not to be included in the area of boiler safety valves.

The area of the superheater safety valve is, in general, to be 25% of the total area of boiler safety valves required.

6.3.5.2 The diameter d of safety valve seatings is to be determined by the following formula:

(1) For saturated steam:

$$d = \sqrt{\frac{DA}{n(10.2p+1)}} \quad \text{mm}$$

where: n – number of valves;

p – design pressure of boiler, as specified in 6.1.3.1 of this Chapter, in MPa;

D – maximum design evaporation of boiler, in kg/h;

A – coefficient, as given in Table 6.3.5.2.

Coefficient A *Table 6.3.5.2*

Lift (mm)	d/24	d/20	d/16	d/12	d/4
Coefficient A	27	23	18.5	14	6.6

(2) For superheated steam:

$$d_1 = d\sqrt[4]{\frac{V_g}{V_B}}$$

where: d_1 — diameter of valve seating for superheated steam, in mm;

d — diameter of valve seating as obtained in the calculation for saturated steam, in mm;

V_g — specific volume of superheated steam, in m^3/kg;

V_B — specific volume of saturated steam, in m^3/kg.

(3) The diameter of full lift safety valves determined by the formula specified above is based on the area not including that of the guides or other obstructions. Then, for full lift safety valves with guides or other obstructions, the diameter of safety valves is to be determined by the total area of valve seatings and guides or other obstructions.

(4) In any case, the valve seating diameter of a safety valve is not to be greater than 100 mm, nor less than 25 mm.

(5) If the diameter of any safety valve fitted on the boiler is less than that required by the Rules, such valve is to be confirmed by testing. The designer is to ensure that safety valves fitted on boilers comply with the testing requirements for safety valves in the Rules.

6.3.5.3 Test of boiler safety valves

(1) For smoke tube boilers with all stop valves closed and under full firing conditions, for a duration of 15 min after the safety valve blows, the maximum pressure value attained is not to exceed 110% of the design pressure.

(2) For water tube boilers under the same conditions described above, for a duration of 7 min after the safety valve blows, the maximum pressure value attained is not to exceed 110% of the design pressure.

(3) The boiler is not to be supplied with water during the test unless it is necessary to maintain the safe working water level.

6.3.5.4 The construction of boiler safety valves is to comply with the following requirements:

(1) The safety valves are to be so locked or sealed that after setting to the working pressure, they cannot be tampered with or overloaded in service, and that they are to be so designed that in the event of fracture of springs they can not lift out of their seats.

(2) The waste steam is not to come into direct contact with the loading springs.

(3) The safety valves are to be so secured to the shell that the passage area is not to be less than the total area of the safety valves in the case of full lift valves (lift $\geq d/4$), and one-half of that area in the case of other safety valves.

(4) Each safety valve chest is to be drained by a pipe led with a continuous fall to the bilge, and no valves or cocks are to be fitted to these drain pipes.
(5) Safety valves are to be provided with easing gear which is to be operable at a safe position from the boiler or engine room platforms.
(6) The spring casing of superheater safety valves are to be ventilated; or other arrangement provided to protect the springs from excessive temperature.
(7) Two safety valves may be fitted in one chest.
6.3.5.5 The safety valves are to be fitted directly to the boiler shell and superheater.
6.3.5.6 For full lift safety valves (lift $\geq d/4$), the passage area of the waste steam pipe is not to be less than twice the total area of safety valves, and for other type of safety valves. This passage area is not to be less than 1.1 times the total area of safety valves.
6.3.5.7 The setting pressure of boiler safety valves is not to be greater than the design pressure of the boiler. A setting pressure of safety valves to lift at not exceeding 103% of the design pressure is acceptable, taking into account the working tolerance.
The setting pressure of superheater safety valves is to be lower than that of the boiler safety valves.
6.3.5.8 It is desirable that there should be a margin between the normal pressure at which the pressure vessel operates and the lowest pressure at which any relief valve is set to lift, to prevent unnecessary lifting of the relief valve.

6.3.6 *Stop valves*
6.3.6.1 The main and auxiliary stop valves are to be secured direct to the boiler shell. The number of auxiliary stop valves is to be minimized as far as practicable so as to minimize the unnecessary openings in the shell. Where the superheater is integral with the boiler, the main stop valve is to be fitted to the outlet of the superheater.
6.3.6.2 Where two or more main boilers or auxiliary boilers for essential services are connected together the following requirements are to be complied with:
(1) Essential services are to be capable of being supplied from at least two boilers.
(2) Stop valves of self-closing or non-return type are to be fitted.

6.3.7 *Blow-off and scum valves*
6.3.7.1 Each boiler is to be fitted with blow-off valves and, if necessary, scum valves. Both blow-off and scum valves (if fitted) are to be secured direct to the boiler shell. Where it is not practicable to attach the blow-off valve direct to water tube boilers, the valve may be placed immediately outside the boiler casing with a steel pipe of substantial thickness fitted between the boiler and valve.
6.3.7.2 Scum valves and blow-off valves are not to be less than 20 mm in diameter, nor to exceed 65 mm.
6.3.7.3 The top edge of scum pans for the surface blow-off is to be placed in the boiler within a range from 25 mm above the lowest water level to 25 mm below the working water level.
The number and arrangement of the scum pans are to be such as to ensure the possibility of blowing off the scum and oil from the entire evaporating surface.

6.3.8 *Pressure gauges*
6.3.8.1 Each boiler is to be fitted with at least one pressure gauge in an easily seen position.
6.3.8.2 The connecting tube for each pressure gauge is to be provided with a joint (including valve or cock) for check of the pressure gauge.
6.3.8.3 Pressure gauges are to be marked with a red line for indicating the working pressure of the boiler. The scale of pressure gauges is to be suitable for the hydraulic test pressure of boilers.

6.3.9 *Sampling valve or cock*
6.3.9.1 Each boiler is to be provided with a sampling valve or cock secured direct to the boiler shell. The valve or cock is not to be fitted on the water gauge standpipe.

6.3.10 *Air cocks*
6.3.10.1 An air valve or cock is to be fitted to the top of steam space of the boiler or drum and is to be, in general, 10 to 15 mm in diameter.

6.3.11 *Superheater mountings*
6.3.11.1 Superheaters are to be provided with the following mountings:
(1) safety valves as specified in 6.3.5.1 and 6.3.5.2 of this Section;
(2) stop valves as specified in 6.3.6.1 of this Section;
(3) drain valves;

(4) air cocks;
(5) thermometers.

6.3.12 *Fittings of shell type exhaust gas heated economizer*

6.3.12.1 All shell type exhaust gas heated economizers that may be isolated from the steam plant system in a flooded condition are to comply with the requirements 6.2.1.4, 6.2.12.1 and 6.3.12.2 to 6.3.12.6.

6.3.12.2 Where a shell type economizer is capable of being isolated from the steam plant system, it is to be provided with at least one safety valve, and when it has a total heating surface of 50 m^2 or more, it is to be provided with at least two safety valves.

6.3.12.3 To avoid the accumulation of condensate water on the outlet side of safety valves, the discharge pipes and/or safety valve housings are to be fitted with drainage arrangements from the lowest part, directed with continuous fall to a position clear of the economizer where it will not pose threats to either personnel or machinery. No valves or cocks are to be fitted in the drainage arrangements.

6.3.12.4 Every shell type economizer is to be provided with a means of indicating the internal pressure. A means of indicating the internal pressure is to be located so that the pressure can be easily read from any position from which the pressure may be controlled.

6.3.12.5 Every economizer is to be provided with arrangements for pre-heating and de-aeration, addition of water treatment or combination thereof to control the quality of feed water to within the manufacturer's recommendations.

6.3.12.6 The manufacturer is to provide operating instructions for each economizer which is to include reference to:

(1) feed water treatment and sampling arrangements;
(2) operating temperatures – exhaust gas and feed water temperatures;
(3) operating pressure;
(4) inspection and cleaning procedures;
(5) records of maintenance and inspection;
(6) the need to maintain adequate water flow through the economizer under all operating conditions;
(7) periodical operational checks of the safety devices to be carried out by the operating personnel and to be documented accordingly;
(8) procedures for using the exhaust gas economizer in the dry condition;
(9) procedures for maintenance and overhaul of safety valves.

Section 4 FITTINGS OF PRESSURE VESSELS

6.4.1 *Fittings*

6.4.1.1 Each pressure vessel is to be provided with the following fittings (for air receivers, see 6.4.1.2 of this Section):

(1) stop valves are to be fitted at the inlet and outlet of the pressure vessels, which are to be secured direct to the cylindrical shell as far as possible;
(2) drain devices including valves and internal pipes (where applicable);
(3) safety devices for preventing overpressure (safety valves are to comply with the requirements of 6.4.1.2(4) of this Section, if fitted);
(4) pressure gauges indicating the medium pressure (where applicable);
(5) level indicators showing the working level of medium (where applicable).

6.4.1.2 Each air receiver is to be provided with the following fittings:

(1) stop valves and pressure gauges as described in 6.4.1.1(1) and (4) of this Section;
(2) drain devices as specified in 6.4.1.1(2) of this Section, which are to be so arranged that they can drain completely the water from the lowest portion of the air receiver;
(3) safety valves. Where the air inlet pipe or the air compressor is fitted with a safety valve capable of preventing the pressure in the air receiver under charging conditions from exceeding the design pressure, the safety valve on the air receiver may be dispensed with, provided that a fusible plug with a melting point approximately at 100℃ and of a size capable of releasing the air in the event of fire is provided;
(4) the capacity of safety valves are to ensure that the air pressure is not to exceed 110% design pressure. Where outlet valves are closed, control valves are to be provided with safety valves.

6.4.1.3 Open drain system is normally to be taken for air receiver. Where closed drain system is taken, due consideration is to be given in design to the possibility of pressure accumulation within the system caused by the blockage of drainage outlet of port by oil/water, and the system has sufficient strength to

withstand the maximum pressure of air receiver.

Section 5 THERMAL OIL HEATERS

6.5.1 *General provisions*

6.5.1.1 This Section applies to thermal oil heaters in which thermal oils are heated to temperatures below their initial boiling point at atmospheric pressure.

6.5.1.2 The detailed requirements for thermal oil systems are given in Section 8, Chapter 4 of this PART.

6.5.2 *Materials and welding*

6.5.2.1 The materials and welding of thermal oil heaters are to comply with the requirements for boilers in this Chapter.

6.5.2.2 Copper and copper alloys are not to be used so as to prevent oxidation of thermal oil.

6.5.3 *Design and manufacture*

6.5.3.1 Thermal oil heaters are to be designed and manufactured in accordance with the requirements for boilers in this Chapter.

6.5.3.2 The surfaces which come into contact with the thermal oil are to be designed for the maximum allowable working pressure, subject to a minimum gauge pressure of 0.6 MPa.

6.5.3.3 Different thermal oil heaters are to be provided with inspection holes as follows:

(1) oil fired heaters are to be provided with inspection holes for examination of the combustion chamber;

(2) exhaust-gas thermal oil heaters are to be provided with manholes serving as inspection holes at the exhaust gas intake and outlet.

6.5.4 *Fittings of thermal oil heaters*

6.5.4.1 Each heater is to be equipped with at least one safety valve complying with the following:

(1) having a blow-off capacity at least equal to the increase in volume of the thermal oil at the maximum heating power. During blow-off, the pressure is not to exceed 110 % of the design pressure of the heater;

(2) the discharge pipe of safety valves is to be led to a thermal oil collecting tank with suitable capacity.

6.5.4.2 Thermal oil heaters are to be provided with means enabling the thermal oil to be completely drained.

6.5.4.3 Thermal oil heaters are to be provided with means to sample the thermal oil.

6.5.4.4 Thermal oil heaters are to be fitted with the following temperature and flow (or pressure) indicators:

(1) thermal oil temperature measuring devices are to be fitted at the thermal oil discharge line of both oil fired heaters and exhaust-gas thermal oil heaters;

(2) devices indicating the flow or pressure of the thermal oil are to be fitted in the thermal oil circulation system.

6.5.4.5 The gas outlet of exhaust-gas thermal oil heaters are to be provided with a temperature sensor and an alarm device for fire detection.

6.5.4.6 Thermal oil heaters are to be provided with means to monitor leakage in accordance with the following requirements:

(1) oil fired heaters are to be provided with a leakage detector which stops the burner and blocks the starting of burner when leakage of thermal oil is detected. If the thermal oil heater is ready to start, when leakage of thermal oil is detected, the starting of burner is to be blocked;

(2) exhaust-gas thermal oil heaters are to be provided with a leakage detector which triggers an alarm when leakage of thermal oil is detected.

6.5.4.7 Heating surfaces of exhaust-gas thermal oil heaters are to be provided with a fixed fire-extinguishing system and a cooling system. Where a pressure water spray system is fitted for this purpose, the following requirements are to be complied with:

(1) the flow rate of the water spraying system is to be at least 5.0 *l*/min for each square meter of the heating surface, and water supply is to be available for at least 20 min;

(2) nozzles are to be so arranged that the required amount of water is sprayed on the entire heating surface;

(3) suitable means for water collection and drainage are to be provided for the exhaust gas line below the heater so as to prevent water entering into engines;

(4) all means of starting valves and pumps necessary for the operation of the water spraying system are to be fitted in an easily accessible place at a safe distance from the heater so as to facilitate the operation by

the personnel in case of the heater catching fire;
(5) concise operating instructions are to be permanently displayed at the operating position of the system.

6.5.5 *Monitoring and protection*

6.5.5.1 Monitoring and protective measures are to be provided for thermal oil heaters according to Table 6.5.5.1.

Monitoring and Alarm Items for Thermal Oil Heaters *Table 6.5.5.1*

Items to be monitored	Local control			Remark
	Indication	Alarm	Automatic shutoff	
Thermal oil expansion tank level	×	Low	×	
Thermal oil flow or pressure	×	Low	×	
Thermal oil outlet temperature	×	High	×	
Combustion air pressure or forced ventilation①		Low or shutoff	×	
Oil fuel pressure①	×	Low		Standby pumps to start automatically
Heavy oil fuel temperature or viscosity①	×	Low and great		For heavy oil fuel only
Uptake temperature①	×	High	×	
Burner flame or ignition①		Flameout/failure	×	Each burner to be monitored
Exhaust temperature②	×	High		

Notes:
× = functional requirement
① Applicable for oil-fired heaters.
② Applicable for exhaust gas heaters.

Section 6 INSTALLATION AND TEST

6.6.1 *Installation of boiler*

6.6.1.1 The boilers are to be securely fixed on board, and the boiler stools and upper part of cylindrical shell are to be secured in such a way as to be able to adapt the thermal expansion of the drums and headers.

6.6.2 *Hydraulic tests*

6.6.2.1 On completion of manufacture or assembly, boilers, boiler components and mountings, fittings, thermal oil heaters and pressure vessels are to withstand hydraulic tests in accordance with Table 6.6.2.1, but test pressure is not to exceed 90% yield force under test temperature.

Hydraulic Test *Table 6.6.2.1*

No.	Name		Test pressure (MPa)	
			On completion of manufacture or assembly	After installation of fittings
1	Drums, header, economizer header		1.5 p	–
2	Overheater header	Working temperature ≤ 350℃	1.5 p	–
		Working temperature > 350℃	$1.5p\frac{R_{eH}^{350}}{R_{eH}^{T}}$	–
3	Boiler, overheater, economizer, thermal oil heater		1.5 p	1.25 p
4	Pressure vessel	Working temperature ≤ 350℃	1.5 p	1.25p (air receiver may be used for gastight test under work pressure)
		Working temperature > 350℃	$1.5p\frac{R_{eH}^{350}}{R_{eH}^{T}}$	
5	Boiler gas pipe, water pipe, overheat pipe and economic pipe		2 p (after bending)	–
6	Overheat steam valve		2.5 p	1.5 p
7	Other boiler valves or fittings		2 p	1.25 p

Notes:
① p — design pressure, in MPa;
② R_{eH}^{350} — specified minimum yield point or 0.2 per cent proof stress of material at 350°C, in N/mm^2;

③ R_{eH}^{T} — specified minimum yield point or 0.2 per cent proof stress of material at the working temperature t (°C), in N/mm^2.

6.6.2.2 Where all components of a boiler, such as drums, headers, etc., have been satisfactorily tested to 1.5 times the design pressure or $1.5p\frac{R_{eH}^{350}}{R_{eH}^{T}}$, on completion of fabrication including attachment of standpipes and pads by welding and heat treatment (but before drilling the tube holes), the boiler may be tested only to 1.25 times the design pressure.

6.6.3 *Shipboard trials*

6.6.3.1 All boilers or thermal oil heaters are to be functionally tested in operation and safety devices after installation.

6.6.3.2 Pressure vessels are to be functionally tested with the systems in which they form a part.

Appendix 1 STRENGTH CALCULATION OF WATER TUBE BOILERS

1 *Cylindrical shells*

1.1 The minimum thickness of the cylindrical shell and tube plate of steam or water drums is to be determined by the following formula:

$$\delta = pD_0/(2[\sigma]\varphi + p) + 0.75 \quad \text{mm}$$

where: p — design pressure of boiler as specified in 6.1.3.1(1) of this Chapter, in MPa;
D_0 — inside diameter of cylindrical shell, in mm;
$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;
φ — minimum strength factor of cylindrical shell, to be determined in accordance with 2.1 of this Appendix.

This formula is applicable only where the resulting thickness does not exceed 0.5 times the inner radius of cylindrical shell.

1.2 The minimum thickness of a cylindrical shell of boilers is not to be less than 6.0 mm.

1.3 For tube plates, such thickness as will give a minimum parallel seat of 9.5 mm, or such greater width as may be necessary to ensure tube tightness (see 6.2.11 of this Chapter).

2 *Strength factor of cylindrical shell*

2.1 The strength factor φ of the cylindrical shell is to be determined as follows:

(1) For welded cylindrical shell unweakened by the tube holes, the strength factor $\varphi$is to be the same as the joint factor φ' of the welded seam given in Table 6.2.6.1 of this Chapter. For seamless cylindrical shell, $\varphi$is equal to 1.

(2) Strength factor of cylindrical shell weakened by the tube holes is to be determined as follows:

① For tube holes of same diameter disposed with regular staggered spacing or regular drilling and having the same pitch in longitudinal direction as shown in Figure 2.1(2)① and Figure 2.1(2)③, the strength factor φ_1 of cylindrical shell is to be determined by the following formula:

$$\varphi_1 = \frac{t_1 - d}{t_1}$$

② For tube holes of same diameter disposed with regular staggered spacing (the holes in any row are shifted in relation to those in the adjacent row by half a pitch in longitudinal direction) and having the pitch both in longitudinal and transverse directions as shown in Figure 2.1(2)①, the strength factor φ_2 of cylindrical shell in longitudinal direction converted from that in diagonal direction is to be determined by the following formula:

$$\varphi_2 = K\varphi_k$$

where: $K = \dfrac{1}{\sqrt{1 - \dfrac{0.75}{(1+m^2)^2}}}$, or to be taken according to Figure 2.1(2)②;

where: $m = \dfrac{t_1}{t_2}$;

$$\varphi_k = \frac{t_k - d}{t_k}.$$

The strength factor φ of cylindrical shell is to be selected from either of the above two values obtained from ① and ②, whichever is the smaller.

③ For tube holes of same diameter disposed with regular drilling as shown in Figure 2.1(2)③, if the pitch t_2 in transverse direction is smaller than pitch $t_1/2$ in longitudinal direction, the strength factor of cylindrical shell is to be taken as 2 φ_3 instead of φ_1 as determined by 2.1(2)①. φ_3 is to be determined by the following formula:

$$\varphi_3 = \frac{t_2 - d}{t_2}$$

The tube pitch t_2 in transverse direction is to be the pitch in way of the centre surface of tube holes.

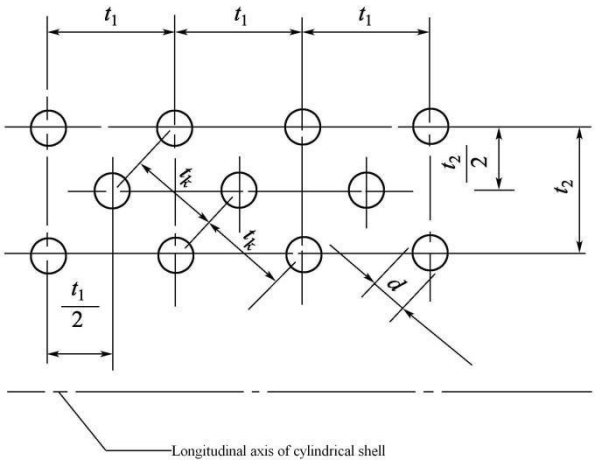

Figure 2.1(2)①

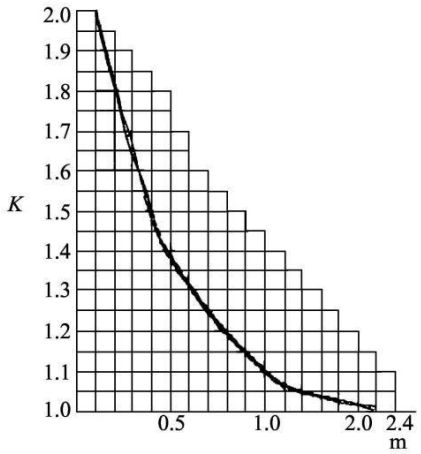

Figure 2.1(2)②

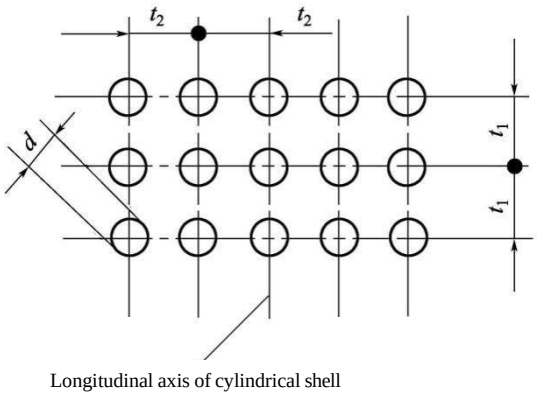

Figure 2.1(2)③

2.2 For tube holes of same diameter with distance between centres adjacent tube holes not constant, as shown in Figure 2.2, the strength factor φ_1 of cylindrical shell is to be determined by the following formula:

$$\varphi_1=\frac{t_1+t'-2d}{t_1+t_1'}$$

In such a case, the double pitch $t_1+t'_1$ chosen is to be that which makes a minimum φ_1, and in no case t'_1 is to be taken as greater than $2t_1$.

2.3 Where tube holes of two different diameters are alternately disposed, the diameter of tube holes is to be replaced by the mean value of the diameters.

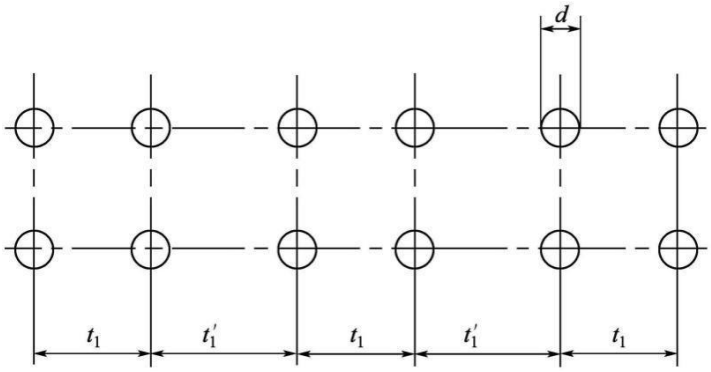

Figure 2.2

3 Compensating effect of tube stubs

3.1 Where a drum or header is drilled for tube stubs fitted by strength welding (see 1.3 of Appendix 5 of this Chapter), the effective diameter of holes used for calculation of the strength in hole line may be replaced by equivalent diameter dc of holes, which is to be taken as:

$$d_c = d - \frac{A}{\delta} \quad \text{mm}$$

where: d — the actual diameter of the hole, in mm;

δ— the thickness of the shell, in mm;

A — the compensating area provided by each tube stub and its welding filets, in mm^2 as shown in Figure 3.1(1) or (2), (the area in the shade line is a half compensating area A), in which:

δ_1 — actual thickness of the tube stub, in mm;

δ_3 — minimum thickness of the tube stub required in 9.1 of this Appendix, in mm;

$h = \sqrt{d\delta_1}$, in mm.

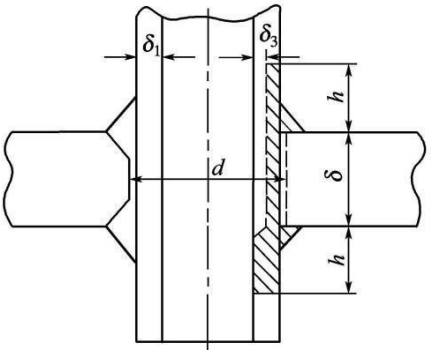

Figure 3.1(1)

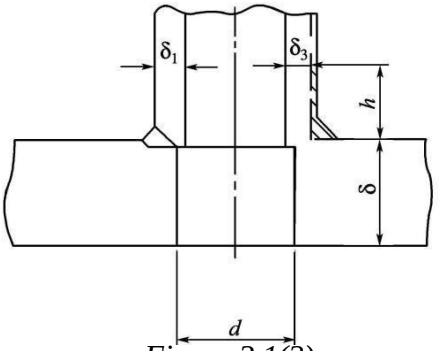

Figure 3.1(2)

3.2 Where the material of the tube stub has an allowable stress lower than that of the shell, the compensating cross-sectional area of the stub is to be multiplied by the following ratio for correction:

allowable stress of stub at design temperature;

allowable stress of shell at design temperature.

4 *Spherical shells*

4.1 The minimum thickness $\delta$of spherical shells subject to internal pressure is to be determined by the following formula:

$$\delta = \frac{pD_0}{4[\sigma]\varphi - p} + 0.75 \quad \text{mm}$$

where: D_0 — inside diameter of the shell, in mm;

p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

[σ]— allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter , in N/mm^2;

φ— strength factor of shell, to be taken in accordance with joint factor of welded seam given in Table 6.2.6.1 of this Chapter.

Spherical shells with openings are to be reinforced in accordance with 2.1 to 2.3 in Appendix 5 of this Chapter.

The above mentioned formula is applicable only where the resulting thickness does not exceed half the internal radius of the shell.

5 *Dished ends*

5.1 The minimum thickness δ of ellipsoidal, torispherical and hemispherical end plates subject to pressure on the concave side, as shown in Figures 5.1(1) to (3), is to be determined by the following formula:

$$\delta = \frac{pD_1 y}{2[\sigma]\varphi} + 0.75 \quad \text{mm}$$

where: D_1 — outside diameter of end plate, in mm;

p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

[σ]— allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;

φ — applying to joint factor of welded seam or the minimum strength factor of drum shell (see 2 in

this Appendix);

y — shape factor, to be obtained from Figure 5.1(4).

For ends without openings, the value of y is to be selected from the group of solid curves, dependent on the ratio of δ/D_1 and H/D_1.

For ends with unreinforced openings, the value of y is selected from the group of dotted curves, dependent on the ratio of $d/\sqrt{D_1\delta}$ and H/D_1, where: d – the diameter of the largest opening in the end plates, in mm (in the case of an elliptical opening, the major axis of the ellipse is to be taken).

For openings with effective reinforcement, the opening factor may be determined according to 2.1 in Appendix 5 of this Chapter. The location of openings and construction of dished ends are to comply with the requirements of 5.2 and 5.3 in this Appendix.

Where the ends are made from more than one plate and welded, the minimum thickness determined by above formula is to be modified by taking account of the joint factor according to 6.2.6.1 of this Chapter.

For ends which are butt welded to the drum shell, the thickness of the edge of the flange for connection to the shell is not to be less than the thickness of an unpierced seamless or welded shell, whichever is applicable, determined in 1.1 of this Appendix.

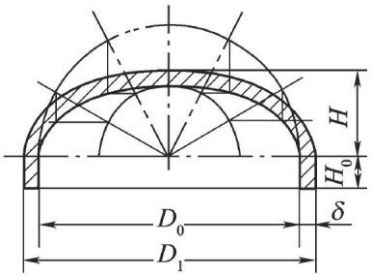

Figure 5.1(1) Ellipsoidal end

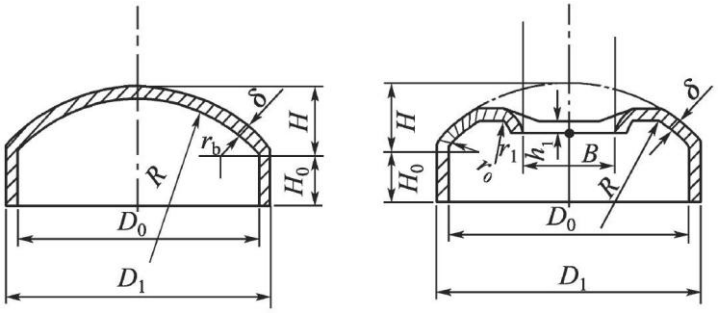

Figure 5.1(2) Torispherical end

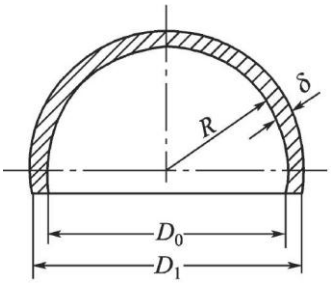

Figure 5.1(3) Hemispherical end

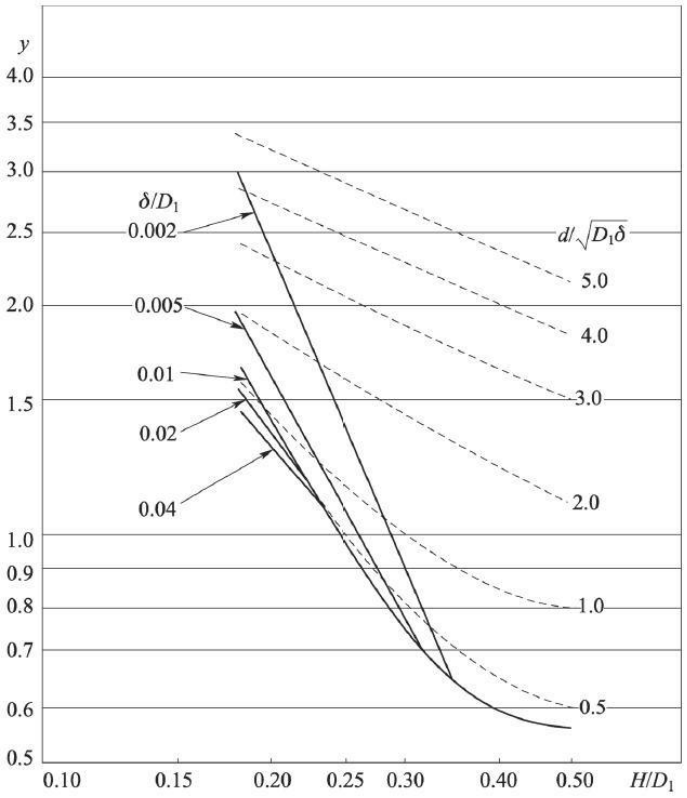

Figure 5.1(4)

5.2 Openings in ellipsoidal and torispherical ends are to be in accordance with the following requirements, as shown in Figure 5.2.

(1) The projectional distance from the edge of hole to the outside edge of the end plate is not to be less than $0.1D_1$.

(2) The projectional distance between two adjacent openings is not to be less than the diameter of the smaller opening.

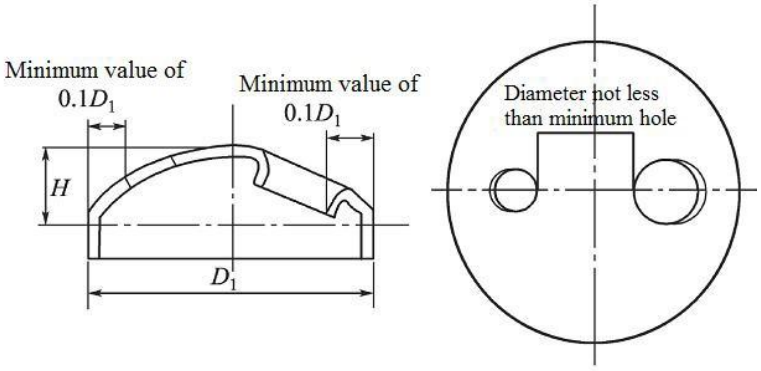

Figure 5.2

5.3 The construction of dished ends is to comply with the following requirements:

(1) For torispherical ends, see Figure 5.1(2) of this Appendix:

$r_b \geq 0.1D_1$ or $r_b \geq 3\delta$, whichever is the greater,

$R \leq D_1$; $H \geq 0.18D_1$ and $H_0 \geq 2\delta$.

(2) For ellipsoidal ends, see Figure 5.1(1) of this Appendix:

$H \geq 0.20D_1$; $H_0 \geq 2\delta$.

(3) For manhole flanges in ellipsoidal, torispherical and hemispherical ends, (in no case is the manhole flange to be taken as the opening reinforcement.), see Figure 5.1 (2) of this Appendix:

$h_1 \geq \sqrt{B\delta}$, where B is the minor axis of manhole;

r_1 = (1.5 to 2) δ.

5.4 The minimum thickness of a dished end is not to be less than 6.0 mm.

6 *Conical ends subject to internal pressure*

6.1 For the construction of conical ends and conical reducing sections, see Figures 6.1(1) to 6.1(4). Connections between cylindrical shell and conical sections and ends are preferably to be by means of a knuckle transition radius. Alternatively, conical sections and ends may be butt welded to cylinders without a knuckle radius where the change in angle of slope ψ between the two sections under consideration does not exceed 30°C.

Conical ends may be constructed of several ring sections of decreasing thickness, as determined by the corresponding decreasing diameter.

The minimum thickness of conical ends or sections is to be determined by the formulae specified in 6.2 and 6.3 of this Appendix, but the thickness of plates at the knuckle and within the distance L from the knuckle is not to be less than the thickness of the section to which it is connected.

6.2 The minimum thickness δ of the cylinder, knuckle and conical end or section at the junction and within the distance L (see Figure 6.1 of this Appendix) from the junction is to be determined by the following formula:

$$\delta = \frac{pD_1K}{2[\sigma]\varphi'} + 0.75 \qquad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

D_1 — outside diameter of the cylinder, conical end or section, in mm, see Figures 6.1(1) to (4);

φ' — joint factor of welded seam, to be selected in accordance with Table 6.2.6.1 of this Chapter. Where the distance of a circumferential seam from the knuckle or junctions is not greater than L. φ' is to be taken 1.0, otherwise, φ' is to be taken as the weld factor appropriate to the circumferential seam;

K — a factor, see Table 6.2;

$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2.

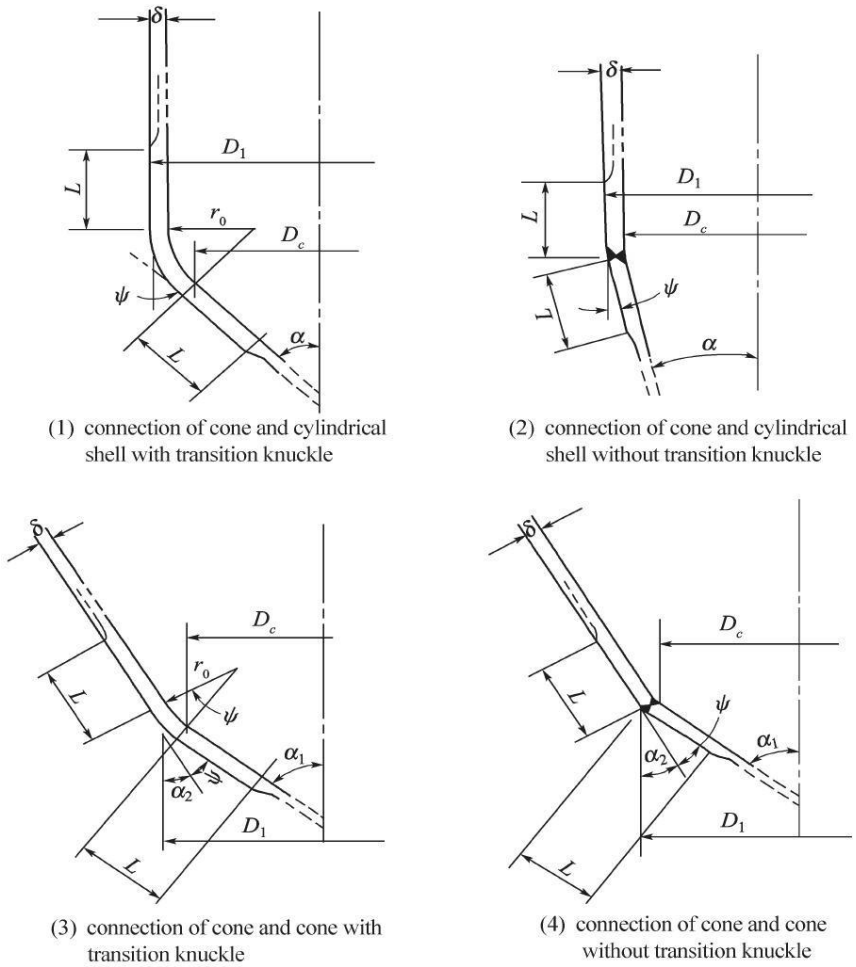

Figure 6.1

Factor *K* **Table 6.2**

r_0/D_1 / ψ	*K* corresponding to r_o / D_1											
	0.01	0.02	0.03	0.04	0.06	0.08	0.10	0.15	0.20	0.30	0.40	0.50

Note: r_0 — inside radius of transition knuckle, in mm, which is to be taken as 0.01 D_c in the case of conical sections without knuckle transition.

The distance L mentioned in this paragraph, as shown in Figures 6.1(1) to (4) of this Appendix, is to be determined by the following formula:

$$L = 0.5\sqrt{\frac{D_1\delta}{\cos\psi}} \qquad \text{mm}$$

where: ψ — difference between angle of slope of two adjoining conical sections, see Figure 6.1 of this Appendix.

6.3 The minimum thickness δ of those parts of conical sections not less than a distance L from the junction with a cylinder or other conical section is to be determined by the following formula:

$$\delta = \frac{pD_c}{2[\sigma]\varphi' - p} \cdot \frac{1}{\cos a} + 0.75 \qquad \text{mm}$$

where: D_c — inside diameter, in mm, of conical section or end at the position under consideration, see Figures 6.1(1) to (4) of this Appendix;

p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

φ' — joint factor of welded seam, to be selected in accordance with Table 6.2.6.1 of this Chapter;

$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;

α — angle of slope of conical section to the vessel axis e.g. α, α_1, α_2, as shown in Figures 6.1(1) to (4). The thickness of conical sections having an angle of inclination to the vessel axis of more than 75° is to be determined as for a flat plate.

7 *Headers*

7.1 The minimum thickness for cylindrical shells of circular section headers is to be calculated in accordance with the requirements of 1.1 of this Appendix.

7.2 The minimum thickness of rectangular section headers is to be determined by the following formulae, the greater of two thicknesses obtained taken:

(1) thickness at the corner of the header:

$$\delta = \frac{p\sqrt{m^2 + l^2}}{2.6[\sigma]} + \sqrt{\frac{4.5M_k p}{[\sigma]}} \qquad \text{mm}$$

(2) thickness at flat surfaces of the header:

$$\delta = \frac{pl}{2.6[\sigma]\varphi} + \sqrt{\frac{4.5M_b p}{[\sigma]\varphi_1}} \qquad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;

m — half the clear width of the header wall to which the strength calculations are made, in mm;

l — half the clear width of another wall of the header, in mm;

M_k — factor of bending moment at the corner of the header, in mm^2:

$$M_k = \frac{1}{3}\frac{m^3 + l^3}{m + l}$$

M_b — factor of bending moment at the flat surface of the header, in mm^2, use the absolute value for negative:

$$M_b = M_k - (m^2 - b^2)/2$$

b — distance measured from the center line of weaken holes to axis of header, in mm, see Figure

7.2(1);

φ,φ_1 — strength factor:

$$\varphi = \frac{t-d}{t}$$

$$\varphi_1 = \varphi \quad \text{when} \quad \frac{d}{m} < 0.6$$

$$\varphi_1 = 1 - 0.6\frac{m}{t} \quad \text{when} \quad \frac{d}{m} \geq 0.6$$

where: t — pitch between holes, in mm;

d — diameter of holes in the header, in mm. For elliptical holes, the value d adopted in $\varphi = (t-d)/t$ is to be replaced by the dimension a in a direction parallel to the longitudinal axis of the header, and value d in d/m is to be replaced by the dimension c in transverse direction, see Figure 7.2(2).

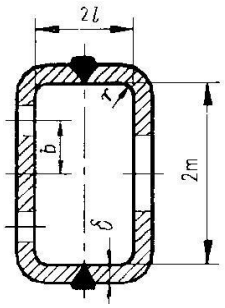

Figure 7.2(1)

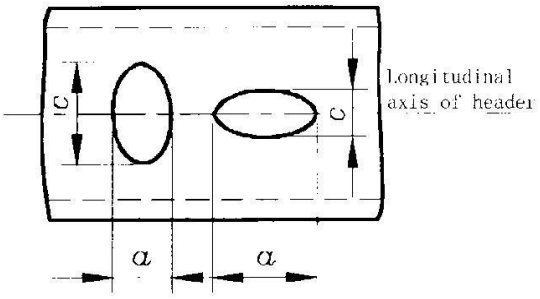

Figure 7.2(2)

7.3 Where the tube holes in the header are disposed with regular staggered spacing symmetrical to the center line of the header (see Figure 7.3), in addition to the calculation of header thickness in accordance with 7.1 or 7.2 of this Appendix, the thickness δ at the diagonal line of tube holes is to be calculated in accordance with the following formula:

$$\delta = \frac{pl}{2.6[\sigma]\varphi_k} + \sqrt{\frac{4.5M_b' p}{[\sigma]\varphi_k}} \quad \text{mm}$$

where: $M_b' = \left[\frac{m^3 + l^3}{3(m+l)} - \frac{m^2}{2}\right]\cos\alpha$;

$\varphi_k = \frac{t_k - d}{t_k}$;

α, t_k — see Figure 7.3.

Other symbols are as defined in 7.2 of this Appendix.

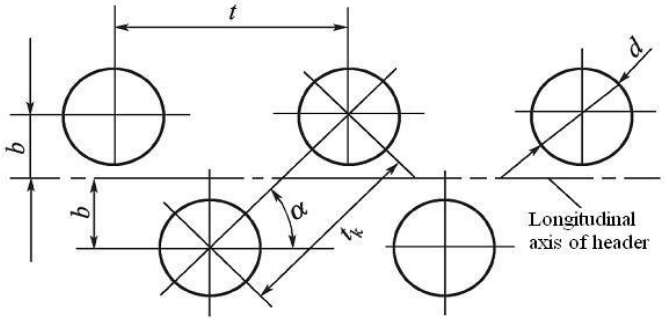

Figure 7.3

7.4 The radius r at the corner of the header, (as shown in Figure 7.2(1)) of this Appendix, is not to be less than 8 mm. Where the header wall is weakened by tube holes, the strength factor φ or φ_k is, as a rule, not to be less than 0.325. The minimum header wall thickness is not to be less than 8 mm, where tubes are fitted by expanding, the minimum header wall thickness is not to be less than 14 mm.

7.5 In welded headers, the distance measured from the center of tube holes to the edge of the welded

seam is not to be less than 0.9 times the diameter of hole, and openings in the welded zone are to be avoided as far as practicable.

8 *Flat end plates*

8.1 The minimum thickness δ of flat end plates is to be determined by the following formula:

$$\delta = CD\sqrt{\frac{p}{[\sigma]}} + 0.75 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;
$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;
D — calculated diameter of cylindrical shell, in mm;
c — constant, to be selected in accordance with Table 8.1.

In the case of rectangular flat end plates, the diameter D for calculations to be replaced by an equivalent diameter determined by the following formula:

$$D = a\sqrt{\frac{2}{1+(\frac{a}{b})^2}}$$

where: a — length of short side of rectangular end plate, in mm;
b — length of long side of rectangular end plate, in mm.

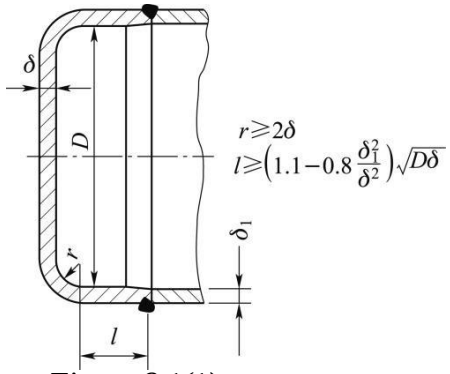

Figure 8.1(1)

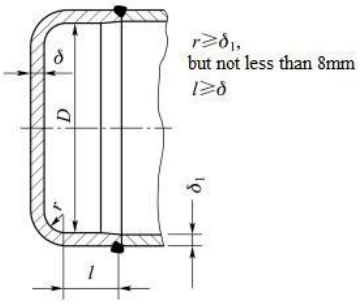

Figure 8.1(2)

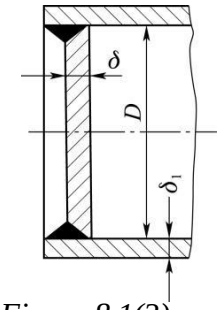

Figure 8.1(3)

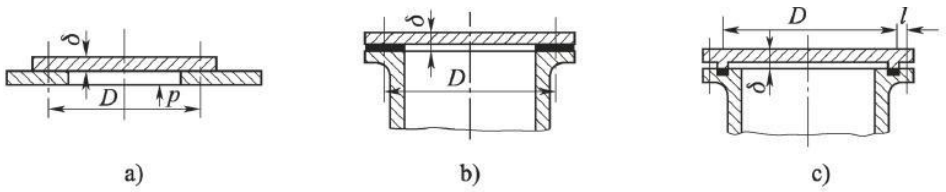

Figure 8.1(4)

Constant *C* **Table 8.1**

Type of end plate	Circular flat end plate *C*	Rectangular flat end plate *C*
Figure 8.1(1)	0.38	–
Figure 8.1(2)	0.43	0.50
Figure 8.1(3); Figure 8.1(4)(a); Figure 8.1(4)(b)	0.52	0.57
Figure 8.1(4)(c) *l*/D = 0.05 *l*/D = 0.10 *l*/D = 0.15	 0.57 0.62 0.67	 – – –

8.2 For circular flat end plates with openings, the minimum thickness of flat end plates is to be increased by 12% of the thickness required in 8.1 of this Appendix.

9 *Boiler tubes subject to internal pressure*

9.1 The minimum wall thickness δ of boiler tubes subject to internal pressure is to be determined by the following formula, but is in no case to be less than that required in 9.2 of this Appendix:

$$\delta = \frac{pD_1}{2[\sigma] + p} + 0.75 \qquad \text{mm}$$

where: D_1 — outside diameter of tubes, in mm;

p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2.

9.2 For boiler tubes calculated by 9.1 of this Appendix, the thickness is in no case to be less than the minimum thickness as given in Table 9.2, and in addition, provision is to be made for minus tolerances of tubes, bending allowances and abnormal corrosion which might be expected in service.

Minimum thickness of boiler tubes *Table 9.2*

Outside diameter of tubes	Minimum thickness	Outside diameter of tubes	Minimum thickness
≤ 38	1.75	> 75 ≤ 95	3.05
> 38 ≤ 50	2.16	> 95 ≤ 100	3.28
> 50 ≤ 70	2.40	> 100 ≤ 125	3.50
> 70 ≤ 75	2.67		

Note: For water tubes subject to internal pressure used for smoke tube boilers and vertical auxiliary boilers, the minimum thickness is not to be less than 3 mm.

Appendix 2 STRENGTH CALCULATION OF HORIZONTAL SMOKE TUBE BOILERS

1 *Cylindrical shell*

1.1 The minimum thickness of the cylindrical shell is to be determined in accordance with 1.1 in Appendix 1 of this Chapter.

1.2 Where the cylindrical shell is made of two sections, the longitudinal welded seams of the two sections are to be shifted for a distance at least 200 mm apart.

1.3 Where the steam dome is connected to the boiler shell by fillet welding, groove welding on both sides or groove welding on one side with sealing run is to be used.

2 *Stayed flat surfaces*

2.1 For flat plates supported by welded-in stays or by welded-in stays and flange connection, the minimum thickness δ is to be determined by the following formula:

$$\delta = Ct\sqrt{\frac{p}{[\sigma]}} + 0.75 \quad \text{mm}$$

where: p – design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

$[\sigma]$– allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;

C – constant, to be selected in accordance with Table 2.1 of this Appendix;

t – calculated pitch of points of support, in mm.

(1) Where the stays are regularly pitched, see Figure 2.1(1):

$$t = \sqrt{a^2 + b^2}$$

(2) Where the stays are irregularly pitched, or within the area enclosing the stays and flanges: When a circle is drawn through three points of support with a result of centre of the circle being situated inside the triangle formed by these three points, $t = d$, see Figure 2.1(2).

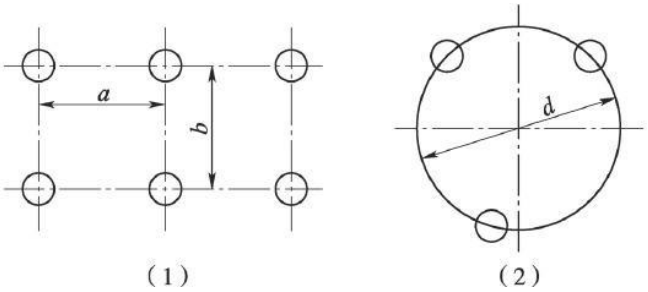

Figure 2.1

Constant *C* **Table 2.1**

Serial No.	Method of support	Constant C②	
		Not exposed to flame	Exposed to flame
1	Flange or fillet welding①	0.38	0.41
2	Stays, with gasket reinforcement, diameter of gasket ≥ 0.67 times stay spacing	0.36	—
3	Stays, with gasket reinforcement, diameter of gasket > 3.5 times diameter of stay	0.38	—
4	Stays, without gasket reinforcement, double-side welded	0.40	0.44
5	Stays, without gasket reinforcement, single-side welded	0.42	0.46
6	Stay tubes	0.46	0.51
7	Smoke tubes (within tube nests)	0.55	0.61

Notes: ① See 3.1(2), (3) and (4) of this Appendix.

② Where a flat plate is provided with two or more methods of support, the constant C is to be taken as the mean of the values for the respective methods adopted.

2.2 The minimum thickness δ of the flat tube plates within the tube nests is to be determined by the following formula:

$$\delta = Ct\sqrt{\frac{p}{[\sigma]}} + 0.75 \qquad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;

C — constant, to be selected in accordance with Table 2.1 of this Appendix, for methods of support, see Figure 4.2 (smoke tubes) and Figure 5.2 (stay tubes) of this Appendix;

t — mean pitch of stay tubes or smoke tubes, in mm.

(1) Where the stay tubes are welded to and the smoke tubes are expanded on the tube plates within the tube nests: t = mean pitch of stay tube supporting tube plates (equal to 1/4 the sum of the sides of a quadrangle formed by four tube centers).

(2) Where the smoke tube are all welded to the tube plates and without stay tubes within the tube nests: t = mean pitch of smoke tubes.

The minimum thickness of tube plates is in no case to be less than the following values:

(1) 10 mm where the tubes are welded to the tubes plates;

(2) 14 mm where the tubes are expanded on the plates; for auxiliary boilers with a design pressure not exceeding 0.78 MPa, 12 mm may be accepted.

2.3 The minimum thickness δ of the flat tube plates in the wide water spaces between tube nests or around tube nests is to be determined by the following formulae:

(1) For wide water spaces between tube nests:

$$\delta = Ct\sqrt{\frac{p}{[\sigma]}} + 0.75 \qquad \text{mm}$$

(2) For flat tube plates around tube nests:

$$\delta = Cd\sqrt{\frac{p}{[\sigma]}} + 0.75 \qquad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;

C — constant, to be selected in accordance with Table 2.1 of this Appendix; for method of support of stay tubes, see Figures 5.2(1) and (2) of this Appendix;

t $= \sqrt{a^2 + b^2}$, in mm

where: a — horizontal pitch of stay tubes, in mm;

b — vertical pitch of stay tubes, in mm;

d — diameter of the maximum circle passing through three points of support of stay tubes and flanges, or of stay tubes and stays, or of stay tubes, stays and flanges, with a result of the centre of the circle being situated inside the triangle formed by these three points, in mm.

2.4 For tube plates the support afforded by the smoke tubes is not to be taken to extend beyond the line enclosing the outer surfaces of the tubes. If the distance between the outside of the wing row of smoke tubes and point of support of flanges is less than the width of margin of flat plate determined in accordance with 2.5 of this Appendix, stay tubes may not be fitted in the wing row.

2.5 For a plate supported by the flues, furnaces or shell, the range from the point of support (see 3 of this Appendix) to the width of margin b obtained by the following formula may be regarded as being supported by the flues, furnaces or shell to which the flat plate is attached:

$$b = \frac{C(\delta - 1)}{\sqrt{p}} \qquad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

δ — thickness of flat plates, in mm;

C = 9.7 for plates not exposed to flame;

C = 9.1 for plates exposed to flame.

Where an unflanged flat plate is welded directly to the flues, furnaces or shell and it is not practicable to effect the full penetration weld from both sides of the flat plate, the constant C used in the formula mentioned above is to be:

C = 7.5 for plates not exposed to flame;

C = 7.1 for plates exposed to flame.

2.6 In addition to the requirements of 2.2 and 2.3 of this Appendix, the minimum thickness δ of combustion chamber tube plates under compression, due to the load on the top plates, is to be checked by the following formula:

$$\delta = \frac{pLt}{193(t-d)} \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;
L — length at the top of combustion chamber along axis of the boilers, measured from the tube plate to the back chamber plate, in mm;
t — horizontal pitch of smoke tubes, in mm;
d — diameter of tube holes, in mm.

2.7 The minimum pitch t of the smoke tubes secured in tube plate is to be determined by the following formula:

expanded tubes:

$$t = 1.125\,d + 12.5 \quad \text{mm}$$

welded tubes:

$t = 1.125d + 7$ mm for gas smoke temperature ≤ 800℃
$t = 1.125d + 9$ mm for gas smoke temperature > 800℃

where: d — outside diameter of smoke tubes, in mm.

2.8 Where flat end plates are flanged for connection to the shell, the inside radius of flanging is not to be less than 1.75 times the thickness of plate, with a minimum of 38 mm.

Where tube plates or flat plates of combustion chambers are flanged for connection to the wrapper plates, the inside radius of flanging is not to be less than thickness of the plate, with a minimum of 25 mm.

3 *Point of support*

3.1 The points of support of boiler flat plates are to comply with the following:

(1) Long stays, short stays, stay tubes, welded-in smoke tubes (within the tube nests only) and flanges may be taken as points of support.

(2) Points of support of flanges:

① Where the inner radius of flange curvature does not exceed 2.5 times the thickness of the plate, the commencement of the flange curvature is to be taken as the point of support.

② Where the inner radius of flange curvature exceed 2.5 times the thickness of the plate, the point of support is to be taken at the position of 2.5 times the plate thickness measured from the inner surface of the flange.

(3) Where the furnace and front end plate are jointed by fillet welding, the outer surface of furnace is to be taken as a point of support.

(4) Where smoke tubes are fitted by means of roller expansion, the flanges of manholes or sight-holes are not to be taken as points of support.

3.2 Stay bars, stay tubes and welded-in smoke tubes, which are used as stays, are to be arranged as uniformly as possible to keep stayed areas as equal as practicable.

3.3 The area A supported by the stay is to be the area on the tube plate that is enclosed by the lines bisecting at right angles the lines joining the stay and the adjacent points of support. Such bisecting lines may approximately be taken as lines joining the center of a tangential circle for three or more adjacent points of support and the midpoint between two adjacent points of support, as shown in Figure 3.3. In respect to stay bars, stay tubes and plain smoke tubes, the stayed area is to be the above area less the area occupied by these stays, while the area occupied by diagonal stay bars are not to be deducted.

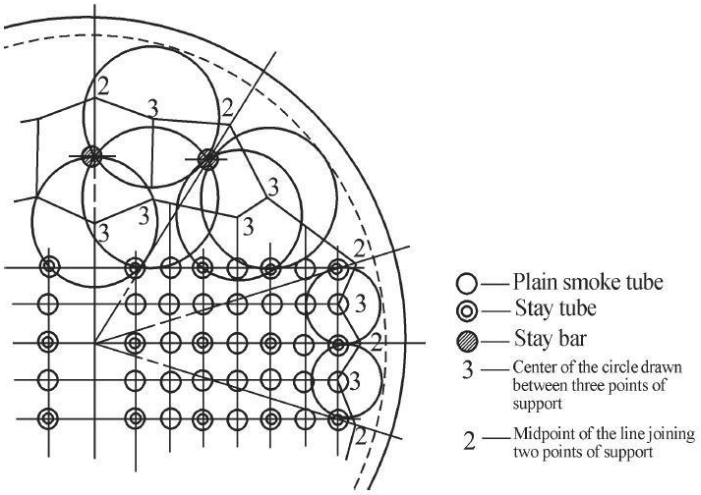

Figure 3.3

4 Plain smoke tubes

4.1 The minimum wall thickness δ of plain smoke tubes is to be determined by the following formula or is to be selected in accordance with Table 6.3.4.1, but in no case is to be less than 3 mm:

$$\delta = \frac{pd_1}{69} + 2 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

d_1 — outside diameter of smoke tubes, in mm.

Minimum wall thickness of smoke tubes *Table 4.1*

Outside diameter of tube, in mm	Wall thickness of tube, in mm				
	3	3.2	3.5	4.0	5.0
	Allowable design pressure, in MPa				
38	1.76				
44.5	1.52	1.81			
51	1.32	1.57	2.01		
57	1.18	1.42	1.77		
63.5	1.08	1.28	1.62	2.16	
70	0.98	1.18	1.47	1.96	
76	0.88	1.08	1.32	1.77	
83	0.78	0.98	1.23	1.62	
89		0.88	1.13	1.52	2.3

4.2 The smoke tubes may be fitted by means of roller expansion or by welding to the plates. Where the smoke tubes are fitted by welding, they are to be in compliance with Figure 4.2.

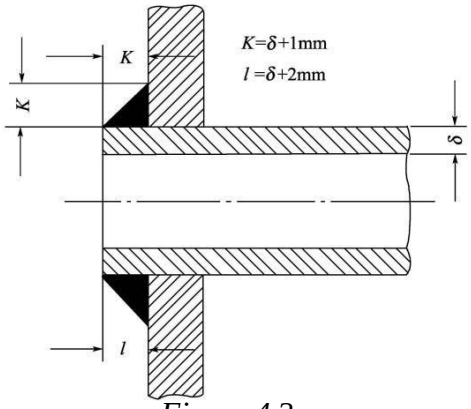

Figure 4.2

5 Stay tubes

5.1 The cross-sectional area F of welded-in stay tubes supporting tube plates is to be determined by the following formula, but in no case is the thickness of stay tubes to be less than 3.5 mm.

$$F = \frac{pA}{[\sigma]} \quad \text{mm}^2$$

where: p – design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

A – area of tube plate supported by one stay tube, in mm^2;

$[\sigma]$ – allowable stress, taken as 67 N/mm^2.

5.2 The stay tubes are to be welded to the tube plates in accordance with Figure 5.2(1) or (2).

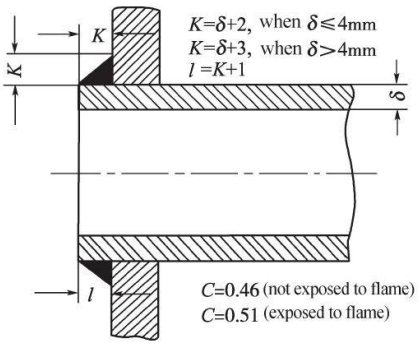

Figure 5.2(1)

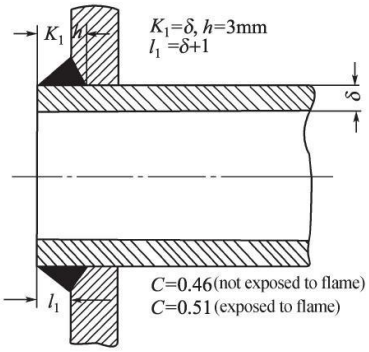

Figure 5.2(2)

6 Stays

6.1 The minimum cross-sectional area F of welded-in stays supporting the flat plates is to be determined by the following formula:

$$F = \frac{pA}{[\sigma]} \quad \text{mm}^2$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

A — maximum area of flat plate supported by one stay, in mm^2;

$[\sigma] = \frac{R_m}{5.3}$, in N/mm^2, for long stays;

R_m — specified tensile strength of materials, in N/mm^2;

$[\sigma]$ = 62, in N/mm^2, for short stays.

6.2 The structural details of welded-in stay bars are to comply with Figures 6.2. The structure shown in Figure 6.2(1) is to be used where the gas temperature is not over 600℃.

6.3 Where stay bars are connected to the flat tube plate and the shell as shown in Figure 6.3, the bar ends inserted into the flat tube plate are to be welded according to the requirements of 6.2. The minimum cross-sectional area F of the stay bar is to be calculated as follows:

$$F = \frac{pA}{[\sigma]\sin\alpha} \quad \text{mm}^2$$

where: α — angle between stay bar and flat tube plate, in degrees, not less than 60°.

Other symbols are the same as in 6.1.

6.4 In Figure 6.3, the throat thickness δ_h of the weld connecting stay bars and the shell is to comply with

$$\delta_h \geq \frac{1.25F}{2L_h} \quad \text{mm}$$

the following in respect to type I welds:

where: F— minimum cross-sectional area of stay bars, in mm^2;

L_h — weld length, in mm.

In any case, the throat thickness δ_h is not to be less than 10 mm.

For type II welds, the throat thickness δ_h is to be taken as d/4.

The weld length is to comply with the following formula:

$$L_h \geq \frac{2.50F}{d} \quad \text{mm}$$

where: F— minimum cross-sectional area of stay bars, in mm^2;

d— diameter of stay bars, in mm.

6.5 The diameter of stay bars is in general not to be less than 25 mm.

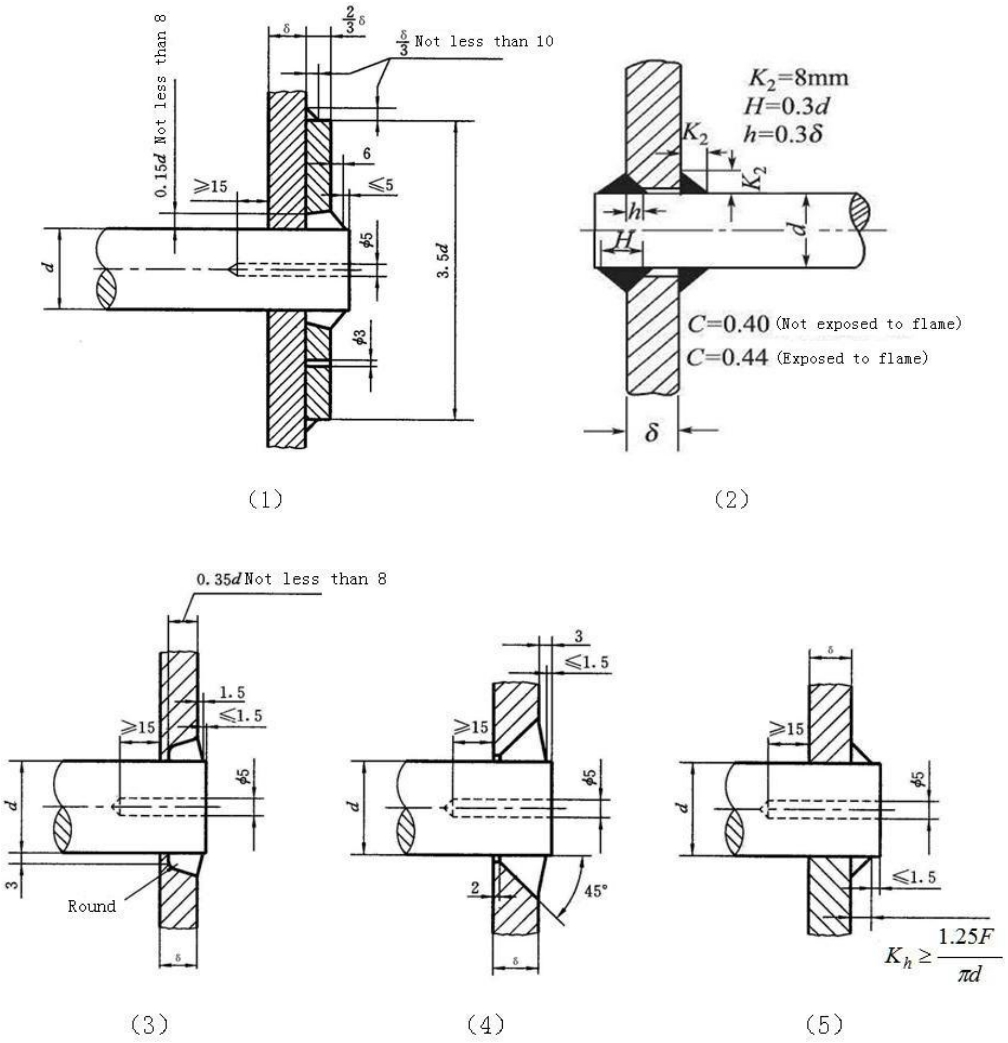

Figure 6.2

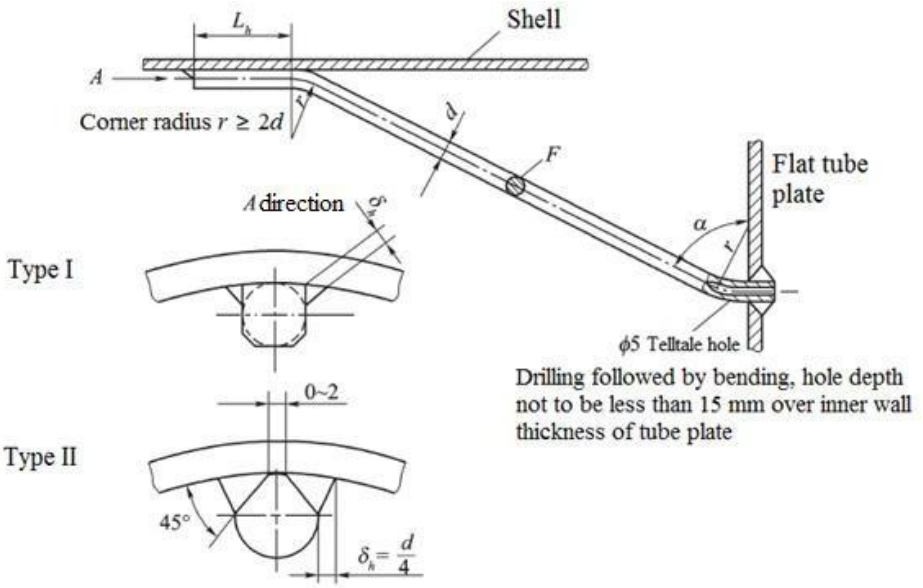

Figure 6.3

7 Furnaces

The minimum thickness δ of corrugated furnaces is to be determined by the following formula:

$$\delta = \frac{pD}{106} + 0.75 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

D — external diameter of the furnace measured at the bottom of the corrugations, in mm.

The minimum thickness δ of plain furnaces or of the cylindrical bottoms of combustion chambers is to be determined by the following formulae, whichever is the greater:

(1) $$\delta = \sqrt{\frac{pD(L+610)}{10300}} + 0.75 \quad \text{mm}$$

(2) $$\delta = \frac{KpD + 0.34L}{110} + 0.75 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

L — maximum length between two points of support of the plain furnace, or for the cylindrical bottom of combustion chamber, in mm. The bisecting plane perpendicular to the axis of reinforcing ring, the commencement of flange curvature of rear tube plate and the fillet welded seam of the front tube plate are to be taken as the point of support for the measurement of the length for calculation of the furnaces;

D — external diameter of the plain furnace or twice the external radius of the cylindrical bottom of combustion chamber, in mm;

$$K = \frac{X}{[R_{eH}^T]}$$

X — specified minimum proof stress ($\sigma_{0.2}$), in N/mm^2, for carbon and carbon-manganese steel with a specified minimum tensile strength of 400 N/mm^2, at a temperature of 90°C above the saturated steam temperature corresponding to the design pressure;

$[R_{eH}^T]$ — specified minimum proof stress ($\sigma_{0.2}$), in N/mm^2, for the steel actually used, at a temperature of 90°C above the saturated steam temperature corresponding to the design pressure .

7.3 The thickness of both plain and corrugated furnaces is in no case to be less than 8 mm, nor greater than 22 mm.

7.4 Where the sections of the plain furnace are jointed by reinforcing rings, the calculated length of each section is in general not to exceed 1000 mm. The reinforcing ring may be of two halves welded together, with an inner radius of curvature R = (3 to 4) δ, and a length of straight portion l =2δ (see Figure 7.4).

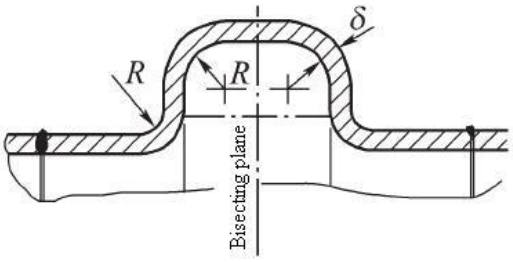

Figure 7.4

8 Crown plates and girders of combustion chambers

8.1 The crown plate and welded-on girders of combustion chambers (see Figure 8.1) are to comply with the following requirements:

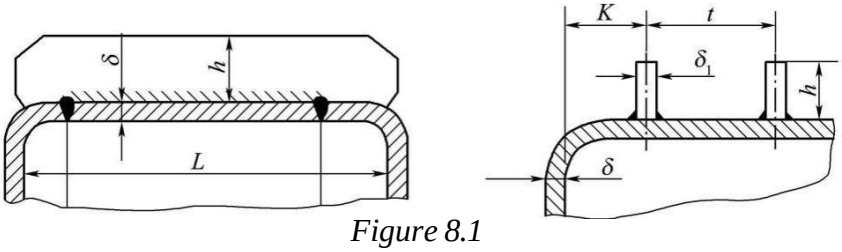

Figure 8.1

(1) The pitch t of the crown plate girders is in general not to be less than 10 δ, but not more than 25 δ.

(2) The thickness of girders δ_1 is not to be less than δ.

(3) The side girders are to be arranged at a distance K equal to or less than the pitch t from the commencement of curvature of the wrapper plates.
(4) The length of the girders is to be equal to the length of the combustion chamber L.
(5) Girders are to have semi-circular scallops above the welded seams of the crown plate, or to have the welds made flush.
(6) The crown plates of the wing combustion chambers are to be made inclined outward not less than 4°.
8.2 The minimum thickness δ of the crown plate of combustion chambers stiffened by welded-on girders is to be determined by the following formula:

$$\delta = 0.56t\sqrt{\frac{p}{[\sigma]}} + 0.75 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;
t — pitch of girders, in mm;
$[\sigma]$ — allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2.
8.3 The minimum depth (h) of welded-on girders on the crown plate of the combustion chambers is to be determined by the following formula:

$$h = \frac{L}{0.68}\sqrt{\frac{pt}{\delta_1 R_m}} \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;
t — pitch of girders, in mm;
R_m — specified tensile strength of steel used for girders, in N/mm^2;
L — length at the top of combustion chamber measured internally from tube plate to back chamber plate, in mm;
δ_1 — thickness of girders, in mm.

Appendix 3 STRENGTH CALCULATION OF VERTICAL AUXILIARY BOILERS

1 *Cylindrical shell*

1.1 The thickness of the cylindrical shell of vertical auxiliary boilers is to be determined in accordance with 1.1 in Appendix 1 of this Chapter, but in no case is to be less than 5 mm.

2 *Dished end plates subject to internal pressure*

2.1 The minimum thickness of ellipsoidal, torispherical and hemispherical end plates without support subject to pressure on the concave side is to be determined in accordance with 5.1 in Appendix 1 of this Chapter. The construction and openings in dished end plates are to comply with the requirements of 5.2 and 5.3 in Appendix 1 of this Chapter.

2.2 The minimum thickness δ of torispherical end plates which are subject to pressure on the concave side and are supported by central uptakes is to be determined by the following formula:

$$\delta = \frac{pR}{1.3[\sigma]} + 0.75 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

R — inside radius of curvature of the end plate, in mm;

$[\sigma]$— allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2.

3 *Flat crowns*

3.1 The minimum thickness δ of flat crown plates of boilers which are supported by central uptakes is to be determined by the following formula:

$$\delta = cd\sqrt{\frac{p}{[\sigma]}} + 0.75 \quad \text{mm}$$

where: p — design pressure of boiler, as specified in 6.1.3.1(1) of this Chapter, in MPa;

$[\sigma]$— allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2;

d — diameter of the largest circle drawn through two points of support by flanges, in mm;

c — constant:

c = 0.47, for plates not exposed to flame;

c = 0.51, for plates exposed to flame.

4 *Tube plates*

4.1 In addition to complying with the requirements of 2.2 to 2.6 in Appendix 2 of this Chapter, the minimum thickness of flat tube plates of vertical boilers having horizontal smoke tubes is to be determined by the following formula, whichever is the greater:

$$\delta = \frac{2pDt}{R_m(t-d)} + 0.75 \quad \text{mm}$$

where: p — design pressure of boiler, as specified in 6.1.3.1(1) of this Chapter, in MPa;

D — twice the radial distance measured from the centre of cylindrical shell to the centre of tubes holes in the outer row, in mm;

t — vertical pitch of tubes, in mm;

d — diameter of tube holes, in mm.

R_m — specified tensile strength of tube plate material, in N/mm^2.

5 *Horizontal shelves of tube plates*

5.1 For vertical boilers having horizontal smoke tubes, the horizontal shelves of the tube plates are to be supported by gussets as follows:

(1) For the combustion chamber tube plate (rear tube plate) the minimum number of gussets is to be:

1 gusset, when $255{,}000 < K \leq 350{,}000$;

2 gussets, when $350{,}000 < K \leq 420{,}000$;

3 gussets, when $K > 420{,}000$.

(2) For the smoke box tube plate (front tube plate) the minimum number of gussets is to be:

1 gusset when $250{,}000 < K \leq 470{,}000$;

2 gussets when $K > 470{,}000$.

Coefficient K is to be obtained from the following formula:

$$K = \frac{10.2ADp}{\delta}$$

where: A — maximum horizontal dimension of the shelf from the inside of the shell plate to the outside of the tube plate, in mm;

D — inside diameter of the boiler shell, in mm;

p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

δ — thickness of tube plates, in mm.

5.2 The shell plates to which the sides of the tube plates are connected are to be 1.6 mm thicker than that required in the formula applicable to shell plates. Where gussets are not fitted to the shelves, the strength of the parts of the circumferential seams at the top and bottom of these plates from the outside of one tube plate to the outside of the other is to be sufficient to withstand the whole load on the boiler end with a factor of safety of not less than 4.5 related to the specified minimum tensile strength of the shell plate material.

5.3 The minimum thickness δ of the vertical furnace or internal uptake of the vertical boiler is to be determined by the following two formulae, whichever is the greater:

(1) $$\delta = \sqrt{\frac{pD(L+610)}{10300}} + C \quad \text{mm}$$

(2) $$\delta = \frac{KpD + 0.34L}{110} + C \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

D — external diameter of the cylindrical furnace or internal uptake, in mm. Where the furnace is tapered, the diameter D is to be taken at the middle point of the calculated length L of the furnace;

L — calculated length of the cylindrical furnace or internal uptake, in mm, i.e. the length between two points of substantial support (see Figure 5.3, where H is the height of dished end). The symbol D is the same as above and Y is to be taken in accordance with Table 5.3. Where the furnace is supported by a circumferential row of regularly arranged stays with a diameter not less than 2.25 δ, and a pitch not exceeding 14 δ, these stays may be regarded as a point of support of calculated length;

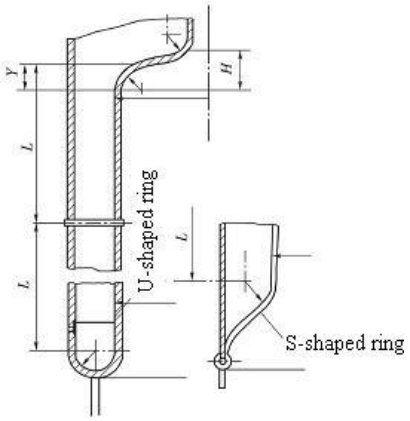

Figure 5.3

Value of *Y* **Table 5.3**

H/D	0.169	0.2	0.25	0.3	0.4	0.5
Y/D	0.07	0.08	0.10	0.12	0.16	0.20

Note: *Y/D* between two adjacent values is determined by means of arithmetic interpolation.

C — allowance:

C = 2 mm for furnace;

C = 4 mm for internal uptake;

$$K = \frac{X}{[R_{eH}^T]}$$

where: X and $[R_{eH}^T]$ are defined in 7.2 in Appendix 2 of this Chapter.

6 *Hemispherical furnaces*

6.1 The minimum thickness δ of unsupported hemispherical furnaces subject to pressure on the convex side is to be determined by the following formula:

$$\delta = \frac{KpR}{61} + 0.75 \quad \text{mm}$$

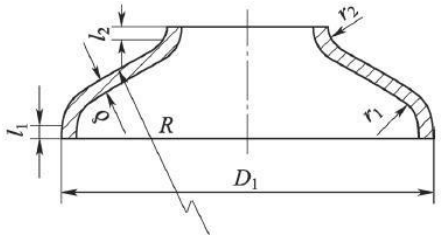
where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

R — outside radius of curvature of the furnace, in mm;

$K = \frac{X}{[R_{eH}^T]}$

where: X and $[R_{eH}^T]$ are defined in 7.2 in Appendix 2 of this Chapter.

7 Torispherical furnaces subject to pressure on the convex side



7.1 The minimum thickness δ of vertical furnace end plates which are subject to pressure on the convex side and are supported by central uptakes (see Figure 7.1 of this Appendix) is to be determined by the following formula:

$$\delta = \frac{pR}{[\sigma]} + 0.75 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

R — outside radius of curvature of the end plates, in mm;

$[\frac{1}{10}]$— allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2.

$R < D_1$;
$r_1 > 4\ \delta$, and > 50 mm;
$r_2 > 2\ \delta$, and > 25 mm;
l_1 and l_2, butt welding structure > 2 δ

Figure 7.1

The minimum thickness δ of dished and flanged ends for vertical boiler furnaces that are subject to pressure on the convex side and are without support from stays, is to be determined by the following formula, but is in no case to be less than the thickness determined by 5.3 of this Appendix:

$$\delta = \frac{KpR}{66} + 0.75 \quad \text{mm}$$

where: δ— the minimum thickness of flanged ends for boiler furnaces, in mm;

p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

R — outside radius of curvature of the end plates, in mm;

$K = \frac{X}{[R_{eH}^T]}$

where: X and $[R_{eH}^T]$ are defined in 7.2 in Appendix 2 of this Chapter.

7 *Ogee rings*

7.1 The minimum thickness δ of the ogee ring which connects the bottom of the furnace to the boiler shell and sustains the whole vertical load on the furnace (see Figure 8.1) is to be determined by the following formula:

$$\delta = \sqrt{\frac{pD(D-d)}{990}} + 0.75 \quad \text{mm}$$

where: p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

D — internal diameter of boiler shell, in mm;

d — outside diameter of the furnace where it connects the ogee ring, in mm.

7.2 The minimum thickness of the U-shaped ring as shown in Figure 8.2 is to be 20% thicker than that obtained from the formula as specified 8.1 of this Appendix.

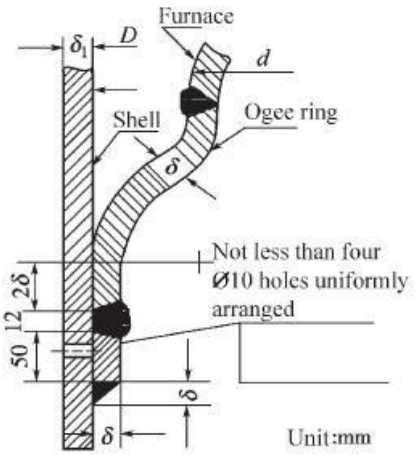


Figure 8.1

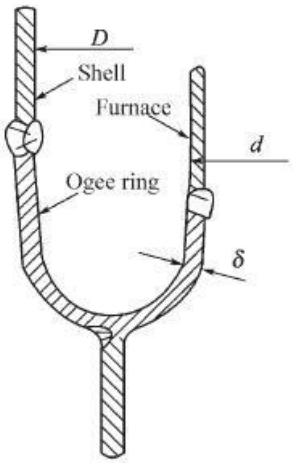

Figure 8.2

Appendix 4 STRENGTH CALCULATION OF PRESSURE VESSELS

1 Strength calculation

1.1 The strength calculation of pressure vessels is to comply with the strength calculation of relevant structure for water tube boilers, contained in Appendix 1 of this Chapter; however, the allowable stresses used in the calculation are to be determined in accordance with 6.2.5.1 of this Chapter. Where an accumulator works at frequently fluctuating working pressure, the allowable stress for its parts is to be appropriately lowered according to the fluctuation condition of pressure.

1.2 For the design pressure and allowable stress of pressure vessels, see 6.1.3.1(1) and 6.2.5.1 of this Chapter.

1.3 The minimum thickness δ of cylindrical shell of the pressure vessels is in no case to be less than that determined by the following formula:

$$\delta \geq 3 + \frac{D_0}{1500} \quad \text{mm}$$

where: D_0 — inside diameter of pressure vessels, in mm.

Appendix 5 OPENINGS AND COMPENSATION

1 *Cylindrical shells*

1.1 Any openings in cylindrical shells, including manholes, hand-holes, openings for standpipes or connecting branches and tube holes, having diameters exceeding those obtained from the formula in 1.2 of this Appendix, are to be reinforced in accordance with the requirements as specified in 1.3 of this Appendix.

1.2 The maximum diameter d of any unreinforced openings is to be determined by the following formula, but in no case is to exceed 200 mm:

$$d = 8.1 \sqrt[3]{D_1\delta(1-K)} \quad \text{mm}$$

where: δ— actual thickness of cylindrical shell, in mm;

D_1— outside diameter of cylindrical shell, in mm;

$K = \dfrac{pD_1}{1.82[\sigma]\delta}$, but not more than 0.99

p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;

$[\sigma]$— allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2.

For elliptical holes arranged with their major axes in longitudinal direction, the major axes are to be taken as the diameter of the opening; for elliptical holes arranged with their minor axes in longitudinal direction, the mean of the major and minor axes are to be taken as the diameter of the openings.

1.3 Openings in cylindrical shells larger than those permitted by 1.2 of this Appendix are to be reinforced by the methods shown in the following Figures:

Figure 1.3(1): Reinforcement by stand-pipe or compensating ring;

Figure 1.3(2): Reinforcement by compensating plate; and

Figure 1.3(3): Combined reinforcement by standpipe or compensating ring together with compensating plate. Reinforcement will be considered adequate when the effective compensating sectional area is equal to or more than the sectional area in way of the openings.

(1) Half the effective compensating sectional area, shown in Figures 1.3(1) to (3) of this Appendix, is to be taken respectively as the total of the following relevant sectional areas:

① Surplus thickness of cylindrical shell multiplied by effective width, i.e. $A_1 = (\delta - \delta_0)\, B$ mm^2;

② Thickness of compensating plate multiplied by effective width, i.e. $A_2 = \delta_2 B$ mm^2;

③ Surplus thickness of standpipe or compensating ring multiplied by effective height, i.e. $A_3 = (\delta_1 - \delta_3)\, h_1$ mm^2;

④ Sectional area of that portion of the standpipe or compensating ring which projects inside the shell, i.e. $A_4 = \delta_1 \times h_2$ mm^2.

(2) Half the sectional area requiring compensating in way of the opening, i.e.:

$$\frac{d_1}{2} \times \delta_0 \quad \text{mm}^2.$$

(3) The symbols used in (1) and (2) above are defined as follows:

δ — actual thickness of the shell, in mm;

δ_0 — thickness, in mm, to be determined in accordance with 1.1 in Appendix 1 of this Chapter, where the strength factor φ of the shell is equal to 1;

δ_1 — actual thickness of standpipes or compensating rings, in mm;

δ_2 — thickness of compensating plates, in mm;

δ_3 — thickness of standpipes, as determined by 9.1 in Appendix 1 of this Chapter, in mm;

d_1 — inside diameter of standpipes or compensating rings;

B = $\sqrt{D_0\delta}$, but not more than $0.5d_1$, in mm;

h_1 = $0.8\sqrt{d_1\delta_1}$, in mm;

h_2 — effective height above the inner side of the shell, in mm, taken as the actual one, but not greater than h_1;

D_0 — inside diameter of cylindrical shell, in mm.

(4) Where the material for the standpipe, compensating ring or compensating plate has an allowable stress lower than that of the shell, the effective compensating sectional area as prescribed in (1) above is to be corrected by multiplying the ratio of allowable stress of standpipe, compensating ring or compensating plate and the allowable stress of shell.

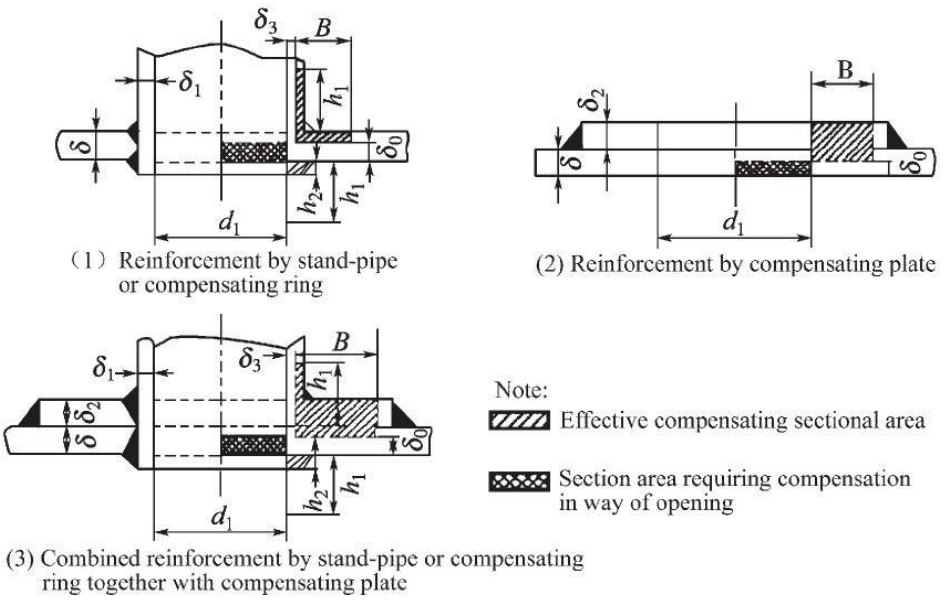

Figure 1.3

2 Dished end plates

2.1 For openings with effective reinforcement in dished end plates, the opening factor $d/\sqrt{D_1\delta}$ is to be calculated as described in 5.1 in Appendix 1 of this Chapter, but d in the formula is to be replaced by the equivalent diameter d' of openings, which is determined by the following formula:

$$d' = d - \frac{A}{\delta} \qquad \text{mm}$$

where: d — actual diameter of opening in dished end plate, in mm;

A — sectional area of the effective reinforcement, in mm^2, to be determined in accordance with 2.2 of this Appendix. The reinforcement is to be so arranged that the distance from its outer edge to the outside edge of dished end plate is not less than $0.1D$; the reinforcement is to be welded on the dished end plate in accordance with 2.3 of this Appendix.

2.2 Openings in dished end plates may be reinforced with standpipe, compensating ring or compensating plate, or with compensating ring combined with compensating plate, see Figure 2.2(1) of this Appendix. The effective compensating sectional area A is to be taken as the total of the following sectional area:

(1) thickness of compensating plate multiplied by effective width, in mm^2, i.e. $A_1 = 2\delta_2 B$ mm^2;

(2) surplus thickness of standpipe or compensating ring multiplied by effective height, i.e. $A_2 = 2\,(\delta_1 - \delta_3)h_1$ mm^2;

(3) thickness of standpipes or compensating ring multiplied by effective height of that portion of standpipe or compensating ring which projects inside the end, i.e. $A_3 = 2\,h_2\delta_1$ mm^2.

where: B — effective width, $B \le \sqrt{2R\delta}$ or $B \le 0.5d$, in mm, the smaller value being taken;

R — inside radius of the spherical portion of the torispherical end, or inside radius of the meridian of the ellipse at the center of the opening for ellipsoidal end, in mm, to be determined by the following formula:

$$R = \frac{[a^4 - x^2(a^2 - b^2)]^{3/2}}{a^4 b} \qquad \text{mm}$$

where: a, b and x are shown in Figure 2.2(2) of this Appendix;

h_1 — effective height, $h_1 = l + \delta + \delta_2$, in mm;

h_2 — effective height, $h_2 = l = \sqrt{d \cdot \delta_1}$, in mm;

δ — thickness of dished end plate, in mm;

δ_1 — thickness of standpipe or compensating ring, in mm;

δ_2 — thickness of compensating plate, in mm;

δ_3 — minimum thickness as required in 1.1 in Appendix 1 of this Chapter, in mm.

Where the reinforcement material for openings in dished end plates has an allowable stress lower than that of the end plate, the effective sectional area of compensating material is to be corrected by multiplying the ratio of allowable stress of compensating material and allowable stress of dished end plate.

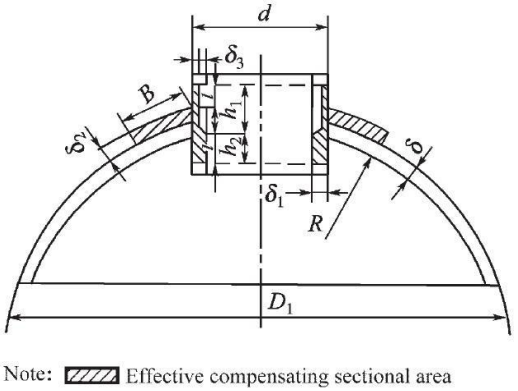

Figure 2.2(1)

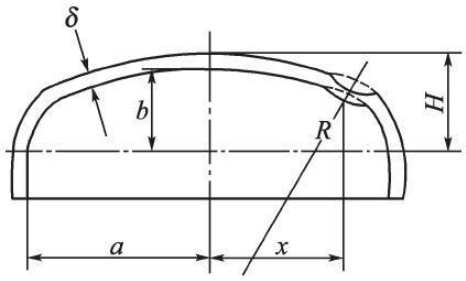

Figure 2.2(2)

2.3 Acceptable welded construction methods for compensating the openings are as shown in Figure 2.3 of this Appendix. Alternative methods of attachment by welding may be accepted provided that equivalent strength of welding is obtained.

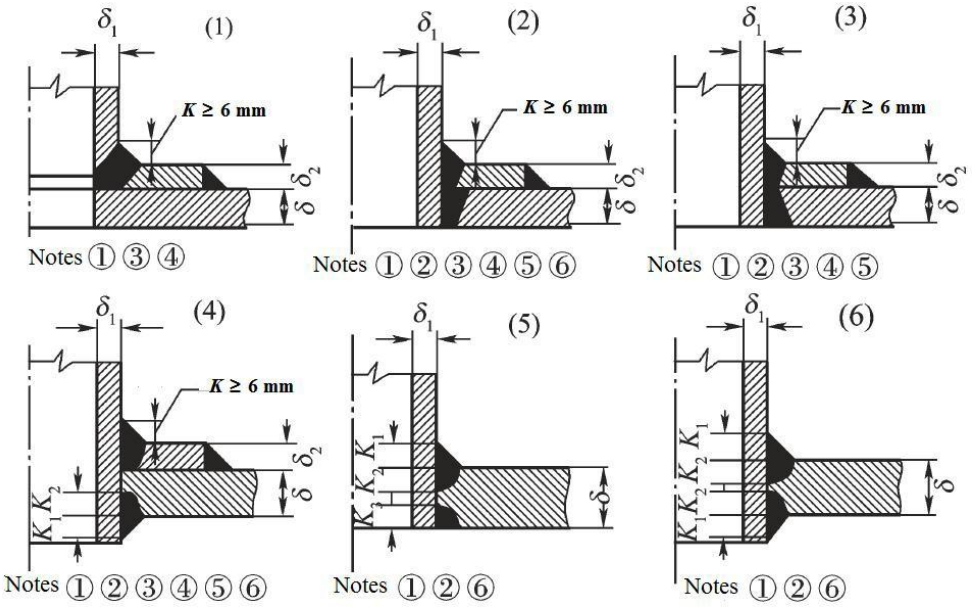

Figure 2.3

Notes:

① Where the thickness of standpipes or compensating rings is less than or equal to 10 mm, the ratio of $\delta_1/\delta$is in general not to be less than 1/5.

② There is to be a clearance between the inside of holes and outside of standpipes or compensating rings. This clearance is not to be more than 3 mm or $\delta_1/2$, whichever is the smaller.

③ There is to be no clearance between compensating plate and the shell plate.

④ Root of welds is to be gouged and a back sealing run is to be applied; where full penetration of welds can be ensured, the back sealing run may be dispensed with.

⑤ Care is to be taken that the welding stress is to be minimized as far as possible during welding.

⑥ Weld sizes:

$K \geq 6$ mm;

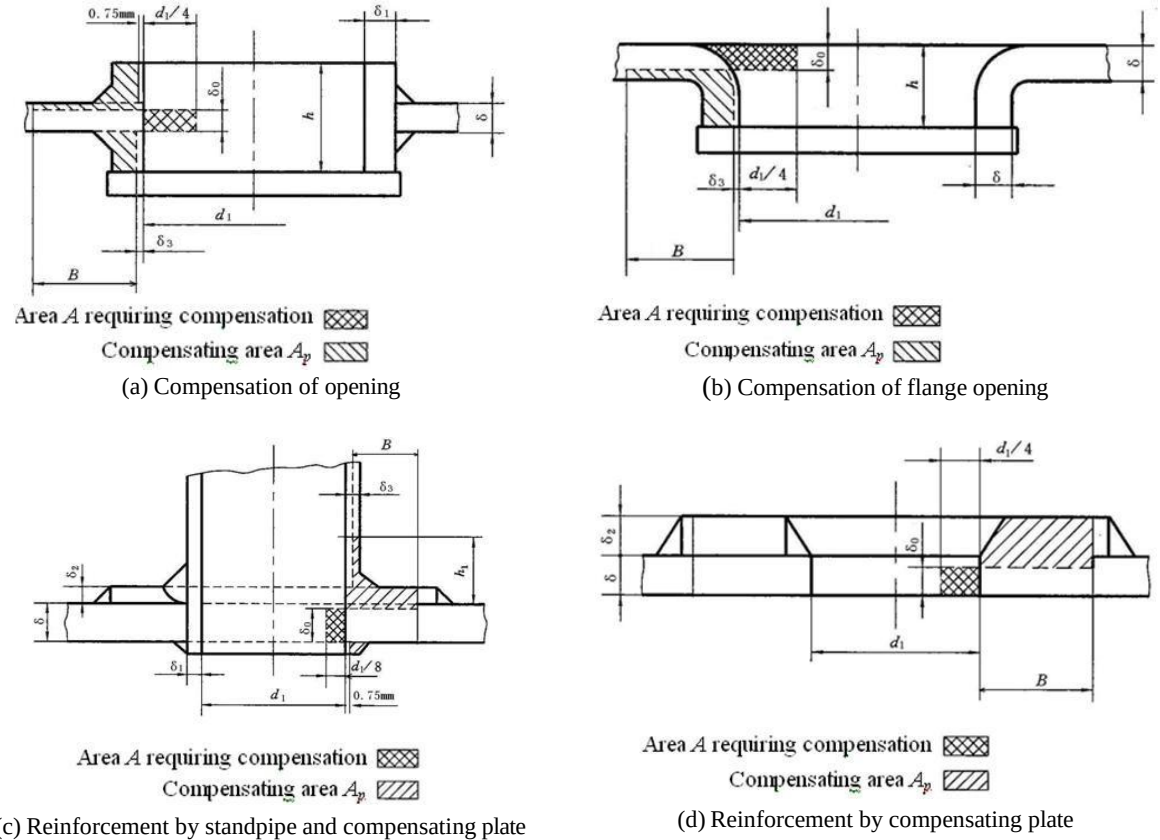
$K_1 + K_2 = 1.5\delta_1$, but K_1 is not to be more than 14 mm or $\delta_1/2$, whichever is lesser;

$K_3 = \delta_1$.

3 *Furnaces*

3.1 Calculations for the reinforcement of furnace openings are to be in accordance with the relevant requirements of Appendix 1.

3.2 In calculating the reinforcement of furnace openings, the furnace thickness is to be assumed as being determined according to 1.1 of Appendix 1, and the strength factor of the shell taken as $\varphi = 1$.



3.3 Furnace openings are not to be reinforced by compensating plates.

4 *Flat plates*

4.1 Where the actual thickness of flat plates complies with the following formula, no compensation of openings is necessary:

$$\delta \geq K_1 \delta_0 \quad \text{mm}$$

where: K_1 = 1.5 (Figure 4.1(a), (b) and (d));
K_1 = 1.25 (Figure 4.1(c)).

(a) Compensation of opening

(b) Compensation of flange opening

(c) Reinforcement by standpipe and compensating plate

(d) Reinforcement by compensating plate

Figure 4.1

Symbols in Figure 4.1:

δ — actual thickness of flat plate, in mm;
δ_0 — minimum thickness of flat plate, in mm, obtained according to the relevant requirements in Appendixes 1 and 2 of this Chapter;
δ_1 — actual thickness of standpipe or reinforcing ring, in mm;
δ_2 — thickness of compensating plate, in mm;
δ_3 — thickness of standpipe, in mm, obtained according to 9.1, Appendix 1 of this Chapter;
d_1 — inner diameter of opening, standpipe or opening ring, in mm;
A — effective breadth of compensation, taken as $0.5d_1$, in mm;
h_1 — effective height of compensation, taken as the lesser of $2.5\delta_1$ and 2.5δ, in mm;
h — height of welded ring or flange height of flange opening, in mm.

4.2 Where the requirements of 4.1 are not complied with, the openings of flat plates are to be reinforced.

4.3 The effective cross-sectional area A_p of compensation and the cross-sectional area A requiring compensation, as shown in Figure 4.1, are to comply with the following formula:

$$A_P \geq A$$

4.4 In (a) and (b) of Figure 4.1, the height of welded ring or the flange height of flange opening is to comply with the following formula:

$$h \geq \sqrt{\delta d_1} \quad \text{mm}$$

In the case of an elliptical opening, the inner diameter d_1 of the opening or opening ring is to be the size of the shorter axis of the ellipse.

Appendix 6 STRENGTH CALCULATION OF STANDPIPES, DOORS FOR MANHOLES AND SIGHT HOLES

1 Standpipes

1.1 The minimum wall thickness δ of standpipes welded direct to the boilers and pressure vessels is not to be less than that determined by 9.1 in Appendix 1 of this Chapter, making such additions as may be necessary on account of bending, static loads and vibration. The wall thickness, however, is not to be less than:

$$\delta = 0.015D + 3.2 \quad \text{mm}$$

where: D — outside diameter of the standpipes, in mm.

1.2 In general, the wall thickness of the standpipes need not exceed that of the shell.
Where a standpipe is connected by screwing, the thickness is to be measured at the root of the thread.

2 Doors for manholes and sight holes

2.1 Doors for manholes and sight holes are to have sufficient strength, and the minimum thickness δ of which is to be determined by the following formula:

$$\delta = 0.8\, ab \sqrt{\frac{p}{(a^2 + b^2)[\sigma]}} + 0.75 \quad \text{mm}$$

where: a — length of major axis of the door, in mm, measured from the centre of jointing surface;
b — length of minor axis of the door, in mm, measured from the certre of jointing surface;
p — design pressure, as specified in 6.1.3.1(1) of this Chapter, in MPa;
$[\sigma]$— allowable stress, to be determined in accordance with 6.2.5.1 of this Chapter, in N/mm^2.

CHAPTER 7 STEAM TURBINES

Section 1 GENERAL PROVISIONS

7.1.1 *Application*

7.1.1.1 The requirements of this Chapter are applicable to steam turbines for main propulsion and to those for essential auxiliary services.

7.1.1.2 The certification requirements and product survey of steam turbines included in 7.1.1.1 of this Section are to comply with the requirements of Chapter 3, PART ONE of the Rules.

7.1.2 *Critical speed*

7.1.2.1 The steam turbines are to be so designed as to ensure freedom from critical speeds within the operating speed range.

7.1.3 *Astern turbines*

7.1.3.1 Main Propulsion turbines are to be installed with astern turbines or incorporated with reversing gears, and the astern power and astern speed are to comply with the relevant requirements in 1.2.4 of this PART.

7.1.4 *Plans and documents*

7.1.4.1 The following plans and documents are to be submitted for approval:

(1) General arrangement;

(2) Section of high-pressure and low-pressure cylinders;

(3) Rotor and shaft bearings;

(4) Nozzles and diaphragms;

(5) Moving blades;

(6) Quill shaft and couplings;

(7) Arrangement of steam turbine pipings (including steam, lub-oil and condensation water piping and indicating the material, size and rated working pressure of pipes);

(8) Technical performance of materials for principal component parts;

(9) Strength calculations for principal component parts;

(10) Welding specifications for principal component parts;

(11) Other plans and documents as deemed necessary by ISC.

7.1.4.2 The following plans and documents are to be submitted for information:

(1) Assembly sectional view of steam turbines;

(2) Specifications of steam turbines.

Section 2 MATERIALS

Testing of materials

The following parts are subject to testing in accordance with the relevant requirements for materials in ISC Rules for Materials and Welding:

(1) rotating parts such as rotors, discs, shafts, shrink rings, blades, toothed couplings and other dynamically loaded components as well as valve spindles and cones;

(2) stationary parts such as casings, diaphragms, nozzles and nozzle boxes, guide vanes, turbine casing bolts, bed frames and bearing seats;

(3) pipes and pipe plates of condenser.

For small auxiliary turbines with inlet steam temperature of 250℃ and below, the test of the material is to be limited only for the material of the blades and shafts.

Non-destructive test

Magnetic particle or liquid penetrant tests are required for rotating parts (including turbine rotor shafts, stiff and flexible couplings, bolts for couplings, blades (sample), gears and other dynamically stressed parts), and at the same time, ultrasonic examination is to be carried out to rotor shafts.

Magnetic particle or liquid penetrant tests are required for stationary parts (including castings and plates for casings) and the spots are to be agreed between the manufacturer and the surveyor.

Non-destructive tests to piping and associated fittings are to comply with the relevant requirements in Chapter 2 of this PART.

Section 3 DESIGN

7.3.1 *Construction of rotors*

7.3.1.1 Smooth fillets are to be provided at abrupt changes of section of blade roots, discs, rotors and bosses. Sharp edges of keyways and balancing holes are to be well rounded.

7.3.1.2 Any two among the wheel blade filling piece, balancing hole and keyway of a disc are not to be arranged on the same radial direction. Where the discs are shrunk on the rotor, the angle subtended between the keyways of any two adjacent discs is not to be less than 90°.

7.3.1.3 Under any working conditions, appropriate radial and axial clearances are to be provided between the moving parts and stationary parts, as well as in the gland sealing of turbines.

7.3.1.4 For propulsion turbines having astern stages, blades are to have sufficient strength to withstand the increased load arising from the counter-steam during reversing.

7.3.1.5 The vibration adjustment for the blading of prototype turbine is to be carried out so as to avoid resonance under service conditions and ensure safe running at any rating.

7.3.2 *Construction of stators*

7.3.2.1 Adequate provision is to be made for the relative thermal expansion of cylinders, diaphragms and nozzle boxes.

7.3.2.2 For the astern turbine, the built-in nozzle box or built-in casing is to be so arranged as to ensure the possibility of free axial or radial expansion relative to the turbine casing. The steam inlet pipe of the astern turbine is not to be rigidly connected to the casing.

7.3.2.3 Where carbon rings are used for outer gland sealing, they are to be capable of being repaired or renewed without opening the casing.

7.3.2.4 Turbine casings are to be provided with suitable drain devices.

7.3.3 *Bearings*

7.3.3.1 The journal bearings and thrust bearings of steam turbines are to be of plain type.

7.3.3.2 It is recommended that self-aligning types be adopted for both journal bearings and thrust bearings of propulsion turbines with high initial steam pressure and turbines designed for quick starting from cold condition. Alternatively, thrust bearings may be of such construction as to ensure uniform distribution of the thrust on the pads.

7.3.3.3 The oil well of the bearing seats is to be so constructed as to ensure that the lubricating oil system is capable of working free from troubles when the ship is under trim or list conditions as specified in 1.2.1.1 of this PART. The temperature of the bearing lubricating oil is not to exceed 70℃.

7.3.4 *Piping*

7.3.4.1 The design of steam piping is to comply with the relevant requirements in Section 3, Chapter 4 of this PART.

7.3.4.2 The design of lubricating oil piping is to comply with the relevant requirements in Section 6, Chapter 4 of this PART.

7.3.4.3 The design of cooling water piping is to comply with the relevant requirements in Section 5, Chapter 4 of this PART.

Section 4 FITTINGS

7.4.1 Overspeed protective devices

7.4.1.1 An overspeed protective device is to be provided for main and auxiliary turbines so as to shut off the steam supply automatically when the turbine speed exceeds 115% of the rated speed.

7.4.1.2 Where two or more turbines are coupled to the same gear wheel set, only one overspeed protective device may be provided for all the turbines.

7.4.1.3 Where exhaust steam from auxiliary systems is led to the main turbine, it is to be cut off at activation of the overspeed protective device.

7.4.1.4 Arrangement is to be provided for shutting off the steam to the main turbines by suitable hand trip

gear situated at the manoeuvring stand and at the turbine itself. Hand tripping for auxiliary turbines is to be arranged in the vicinity of the turbine overspeed protective device (The hand trip gear means any devices by hand manoeuvring, neglecting the executive action i.e. either by mechanical means or by external power means).

7.4.2 Low pressure protective devices for lubricating oil

7.4.2.1 Main ahead turbines are to be provided with a quick acting device which will automatically shut off the steam supply in the case of dangerous lowering of oil pressure in the bearing lubricating system. This device is to be so arranged as not to prevent the admission of steam to the astern turbine for braking purposes.

Where deemed necessary, appropriate means are to be provided to protect the turbines in case of:

(1) abnormal axial rotor displacement (see 7.4.4 Protective devices for axial displacement);

(2) excessive condenser pressure;

(3) high condensate level.

7.4.2.2 Auxiliary turbines having governors operated other than hydraulically in which the lubricating oil is inherent in the system, are to be provided with an alarm device and a means of shutting off the steam supply in the case of lowering of oil pressure in the bearing lubricating oil system.

7.4.2.3 Main steam turbines are to fitted with a satisfactory emergency supply of lubricating oil which will come into use automatically when the pressure drops below a predetermined value. Suitable arrangement for cooling the bearings after stopping is to be required. For emergency supply system of oil, see 4.6.3 of this PART.

7.4.3 Speed governors

7.4.3.1 Turbines for propulsion generators and auxiliary turbines intended for driving electric generators are to be provided with reliable governors.

7.4.3.2 The governor of a turbine installation incorporating electric transmission, controllable pitch propeller or reverse gear is to be capable of controlling the speed under various working conditions, without bringing the automatic overspeed protective device into action when full load is suddenly taken off.

7.4.3.3 The governors of auxiliary turbines intended for driving electric generators, in addition to the relevant requirements contained in Section 2, Chapter 3 of PART FOUR of the Rules, are to comply with the following:

Momentary variation is not to exceed 10% of the rated speed and permanent variation not to exceed 5% of the rated speed when full load is suddenly taken off.

Momentary variation is not to exceed 10% of the rated speed and permanent variation not to exceed 5% of the rated speed when 50% of the rated load of the generator is suddenly put on from no-load condition, followed by the remaining 50% load after an interval sufficient to restore the speed to steady state. The recovery time for the engine speed (i.e. the time for speed fluctuation ratio to return to ±1%) is not to exceed 5 s.

7.4.4 Protective devices for axial displacement

7.4.4.1 All propulsion turbines are to be equipped with devices indicating the axial position of the rotor relative to the stator.

7.4.4.2 A protective device is to be provided for main turbines so as to shut off the steam automatically when axial displacement of the turbine rotor is in excess of the specified value.

7.4.5 Gland sealing and condensate systems

7.4.5.1 In the arrangement of the gland sealing system, the pipes are to be made self-draining and every precaution is to be taken against the possibility of condensate entering the turbines. In the air ejector re-circulating water system, the connection to the condenser is to be so located that water can not impinge on the rotor or casing.

7.4.6 Safety devices for manoeuvring

7.4.6.1 Screw-down non-return valves or other approved means are to be fitted in steam bleeding-off pipes to prevent any steam and water from returning to the turbines.

7.4.6.2 Propulsion turbines are to be provided with power-driven turning gear. An interlock device is to be provided between turbine and turning gear to prevent the turbine from being started until the turning gear is disengaged.

7.4.6.3 An interlock device is to be provided for the ahead and astern manoeuvring valves of propulsion

turbines. A screw-down valve is also required between those valves.

7.4.6.4 Efficient steam strainers are to be provided close to the inlets to ahead and astern high pressure turbines or alternatively at the inlets to manoeuvring valves.

7.4.7 Alarm devices

7.4.7.1 Propulsion turbines are to be fitted with alarm devices giving both audible and visible warnings when the vacuum in the condenser is lower than the specified value.

7.4.7.2 To provide a warning to personnel in the vicinity of the exhaust end steam turbines of excessive pressure, a sentinel valve or equivalent is to be provided at the exhaust end of all turbines. The valve discharge outlets are to be visible and suitably guarded if necessary. When, for auxiliary turbines, the inlet steam pressure exceeds the pressure for which the exhaust casing and associated piping up to exhaust valve are designed, means to relieve the excess pressure are to be provided.

7.4.8 Emergency arrangements

7.4.8.1 In single screw ships fitted with cross compound steam turbines, the arrangements are to be such as to enable safe navigation when the steam supply to any one of the turbines is required to be isolated. For this emergency operation purpose, the steam may be led directly to the L.P. turbine and either the H.P. or M.P. turbine can exhaust direct to the condenser. Adequate arrangements and controls are to be provided for these operating conditions so that the pressure and temperature of the steam will not exceed those which the turbines and condenser can safely withstand.

7.4.8.2 The necessary pipes and valves for these arrangements are to be readily available and properly marked. A fit up test of all combination of pipes and valves is to be performed prior to the first sea trials.

7.4.8.3 The permissible power/speeds when operating without one of the turbines (all combinations) is to be specified and information provided on board.

7.4.8.4 The operation of the turbines under emergency conditions is to be assessed for the potential influence on shaft alignment and gear teeth loading conditions.

Section 5 TESTS AND TRIALS

7.5.1 *General requirements*

7.5.1.1 Turbines covered in 7.1.1.1 of this Chapter are to be subject to following tests and surveys.

7.5.2 *Material test and non-destructive test*

7.5.2.1 All components of turbines are to be subject to material test and non-destructive test according to the relevant requirements of 7.2.1 and 7.2.2 of this Chapter in the presence of the Surveyor.

7.5.3 *Test pressure*

7.5.3.1 All components of turbines together with associated equipment are to be tested to the hydraulic pressures as given in Table 7.5.3.1.

Hydraulic test pressure *Table 7.5.3.1*

Name	Test pressure (MPa)
Cylinder, steam receiver, nozzle box	1.5 p, but not less than 0.2
Operating valve	2 p
Steam jacket space of condenser	0.1
Cooling water jacket space of condenser	1.5 p

Note: p – working pressure, in MPa.

7.5.4 *Thermal stability test of rotors*

7.5.4.1 Where the inlet steam temperature exceeds 400 ℃ , the solid forged rotors or welded rotors of propulsion turbines are to be subject to a thermal stability test after heat treatment and rough machining of the forging.

7.5.5 *Dynamical balance test of rotors*

7.5.5.1 Rotors together with the half-coupling are to be dynamically balanced on completion of final assembly.

7.5.6 *Maximum load test of diaphragm*

7.5.6.1 All diaphragms of the first turbine of the same type are to be subject to a maximum load test for

checking their deflections.

7.5.7 *Safety relief valve test*

7.5.7.1 Safety relief valves required by Section 4 of this Chapter are to be subject to opening and closing test according to the design pressure of manufacturer.

7.5.8 *Workshop trials*

7.5.8.1 Upon completion of fabrication and assembly, each steam turbine is to be subject to a shop trial in accordance with manufacturer's test schedule, which is to be submitted for review before the trial.

7.5.8.2 The test schedule is to specify the duration of tests and to include full load test, half load response test, etc.

7.5.8.3 The overspeed protective device is to be tested.

7.5.9 *Shipboard trials*

7.5.9.1 After installation on board, each steam turbine, including all control and safety systems, is to be operated to satisfactorily demonstrate its function.

7.5.9.2 Freedom of steam turbine from harmful vibration at speeds within the operating range is to be demonstrated.

7.5.9.3 The reversing characteristics of propulsion turbine plants are to be demonstrated.

7.5.9.4 The function of governor is to be demonstrated.

CHAPTER 8 GAS TURBINES

Section 1 GENERAL PROVISIONS

8.1.1 *Application*

8.1.1.1 This Chapter applies to gas turbines for main propulsion and to those for essential and auxiliary services.

8.1.1.2 The certification requirements and product survey of gas turbines included in 8.1.1.1 of this Section are to comply with the relevant requirements of Chapter 3, PART ONE of the Rules.

8.1.2 *Rating*

8.1.2.1 The rated output is defined as the maximum continuous power developed by gas turbines for continuous running under the following reference conditions:

(1) air at compressor inlet:

① temperature of 15℃;

② absolute pressure of 101.325 kPa;

③ relative humidity of 60%.

(2) cooling water inlet temperature is of 15℃(if applicable);

(3) static pressure of the exhaust in way of turbine exhaust flange (or heat recuperator outlet) is of 101.325 kPa.

The rated speed is defined as the speed corresponding to the rated output.

8.1.3 *Correction curves*

8.1.3.1 Correction curves are to be submitted by the manufacturers indicating the variation in major performance of gas turbines relating to ambient conditions.

8.1.4 *Astern running*

8.1.4.1 The astern power of the main propulsion gas turbines is to comply with the requirements of 1.2.4 of this PART.

8.1.5 *Miscellaneous*

8.1.5.1 The construction and arrangement of the components and systems of gas turbines are to be in compliance with the provisions as specified in 1.2.1.1 of this PART.

8.1.5.2 The welding of gas turbine components is to comply with the relevant provisions as specified in ISC Rules for Materials and Welding.

8.1.5.3 Automation systems of gas turbines are to comply with the relevant provisions as specified in PART SEVEN of the Rules.

8.1.5.4 Lubricating oil systems of gas turbines are to comply with the relevant provisions of Section 6, Chapter 4 of this PART.

8.1.6 *Plans and documents*

8.1.6.1 The following plans and documents are to be submitted for approval:

(1) Sectional assembly of gas turbines and compressors;

(2) Rotors, including blades;

(3) Combustion chambers and heat exchangers;

(4) Fuel oil systems;

(5) Lubricating oil systems;

(6) Details of high temperature characteristics of the materials, including(at the working temperatures) the associated creep rate and rupture strength for the designed service life (where applicable), fatigue strength, corrosion resistance and scaling properties. Particulars of heat treatment, including stress relief;

(7) Calculations of the critical speeds;

(8) Calculations of strength for major components;

(9) Details of the automatic safety devices;

(10) Specifications of gas turbines, including but not limited to the following:

① essential parameters, e.g. mass, time between overhaul, maximum continuous power, maximum air mass flow rate, temperature at main sections, pressure at main sections, revolving speed of gas

generator, revolving speed of power turbine, maximum allowable rate of load increase/reduction and maximum allowable rate of revolving speed increase /reduction;

② Usage limitations, e.g., maximum allowable heel and trim, maximum allowable roll and pitch, maximum allowable axial force of output shaft, maximum allowable shear force and bending moment of output shaft, maximum allowable acceleration load, maximum allowable salt content in inlet air and fuel type, etc.

(11) Other plans and documents as deemed necessary by ISC.

8.1.6.2 The following plans and documents are to be submitted for information:

(1) Principal particulars of gas turbines, characteristics of compressors (including surge margin in various operation conditions), overall performance curves of gas turbines, performance curves indicating power and speed dependency on ambient temperature, gas turbine performance or power loss as a function of operation time, and expected recovery performance after a complete overhaul, etc.;

(2) General section of gas turbines and compressors;

(3) The failure mode and effect analysis (FMEA) of the automatic safety devices;

(4) Operation and maintenance manuals of gas turbines;

(5) Other plans and documents as deemed necessary by ISC.

Section 2 MATERIALS

7.2.1 *General requirements*

7.2.1.1 Materials used for the construction of gas turbine components are to comply with the relevant provisions as specified in ISC Rules for Materials and Welding. Where materials other than those mentioned above are used, relevant documents are to be submitted for approval.

7.2.2 *High temperature properties*

7.2.2.1 Gas turbine components working under high temperature are to have high temperature characteristics consistent with the working temperature (such as creep rate, rupture strength, fatigue strength, corrosion resistance and scaling properties).

7.2.3 *Testing of materials*

7.2.3.1 The following parts of gas turbines are to be in accordance with the relevant requirements for testing of materials in ISC Rules for Materials and Welding:

(1) shafts, turbine and wheel of compressor, guide vanes and blades;

(2) turbine and casing of compressor, combustion chambers and heat exchangers.

For low-power gas turbines, materials of shafts, turbines and wheels of compressors are also to be subject to material tests.

7.2.4 *Non-destructive testing*

7.2.4.1 Non-destructive tests are required for rotating parts (including welded joints),including compressors and turbine rotor shafts, stiff and flexible couplings, bolts for couplings, blades, discs, integral pinions and gears and other dynamically stressed parts. Details including test methods and results are to be assessed in accordance with acceptable recognized standards.

7.2.4.2 Non-destructive tests are required for stationary parts (including castings for casings intended for a temperature exceeding 230℃ and plates for casings intended for a temperature exceeding 370℃ or pressure exceeding 4 MPa). Details including test methods and results are to be assessed in accordance with acceptable recognized standards.

7.2.4.3 Non-destructive tests to piping and associated fittings are to comply with the relevant requirements in Chapter 2 of this PART.

Section 3 DESIGN AND CONSTRUCTION

8.3.1 *General requirements*

8.3.1.1 All parts of gas turbines, compressors, etc., are to have clearances and fits appropriate to and consistent with their respective thermal expansion.

8.3.1.2 Gas turbine bearings are to be so disposed and supported that lubrication cannot be impaired by

hot gas. Effective means are to be provided to prevent leakage oil coming into contact with hot parts.
8.3.1.3 Gas turbines are to be so designed that escape of fragments due to burst of rotors can be avoided as far as practicable.

8.3.2 *Stress analysis*
8.3.2.1 Stress analysis to each rotor including rotor discs, blades and shafts at maximum designed working condition is to be submitted by the manufacturers.

8.3.3 *Vibration*
8.3.3.1 Gas turbine and compressor rotor discs and blades are to be designed and manufactured to be free from undue vibration within the operating speed range. Calculations of the critical speed are to be submitted. Where critical speeds are found by calculation to occur within the operating speed range, vibration tests may be required.

8.3.4 *Air inlet and exhaust gas systems*
8.3.4.1 The air-inlet system is to be designed to minimize the entrance of harmful foreign matter into the compressors and gas turbines.
8.3.4.2 Appropriate means is to be provided to prevent icing of air inlet pipes.
8.3.4.3 The air-inlet pipelines are to be designed to minimize the risk of loose parts entering the gas turbines due to air flow or corrosion.
8.3.4.4 The air-inlet system is to be provided with appropriate filtering equipment to keep water, particulate matters and corrosive sea salt within the limits specified by gas turbine manufacturers.
8.3.4.5 Where multiple turbines are arranged, each gas turbine is to be provided with separate inlet pipes and exhaust pipes, so that simultaneous operation of turbines is not to harm the operation condition of any turbine and induced circulation through a stopped gas turbine is prevented.
8.3.4.6 Pressure drop of inlet and exhaust systems is not to exceed the range specified by gas turbine manufacturers.
8.3.4.7 The arrangement of the turbine exhaust system is to be such as to prevent exhaust gas being drawn into the compressors.

8.3.5 *Fuel and salt deposits*
8.3.5.1 Where it is intended to burn non-distillate fuels forming harmful deposits, adequate provision is to be made for periodic removal of the deposits.
8.3.5.2 Means for preventing the accumulation of salt deposits in the compressors and turbines are to be provided.

8.3.6 *Turning gear*
8.3.6.1 Gas turbines are to be equipped with turning gear. Where gas turbines are provided with remotely controlled starting or automatic starting function, in order to prevent the starting of gas turbines during engagement of turning gear, the turning gear is to be interlocked with starting arrangements. If gas turbines are not provided with remotely controlled starting or automatic starting function, at least safe operation instructions with a warning notice are to be provided, indicating that “Starting of gas turbines during engagement of turning gear is prohibited”.

8.3.7 *Starting system*
8.3.7.1 The starting arrangements and starting air pipe systems are to comply with the relevant provisions as stated in Section 5, Chapter 9 of this PART, where applicable.
8.3.7.2 Automatic or interlocked means are to be provided for clearing all parts of the main gas turbine of the accumulation of liquid fuel or for purging gaseous fuel, before ignition commences on starting or recommences after failure to start. Where means are provided for automatic starting, a purging program is to be included in the starting sequence.
8.3.7.3 Starting devices are to be so arranged that firing operation is discontinued and main fuel valve is closed within pre-determined time, when ignition is failed.

8.3.8 *Inspection openings*
8.3.8.1 It is recommended that inspection openings be provided to permit inspection of rotors of the compressors and gas turbines and the inside of the burner with bore scope or other instrument without dismantling the gas turbines.

8.3.9 *Instrumentation*

8.3.9.1 Main propulsion gas turbines are to be provided with monitoring device fitted on the control platforms to display and/or record various principal parameters such as temperature, pressure, speed, etc.

8.3.9.2 Monitoring devices are at least to indicate the following:

(1) air pressure and temperature at compressor inlet;

(2) gas temperature at burner outlet;

(3) lubricating oil pressure and temperature;

(4) rotor speed.

8.3.10 *Installation*

8.3.10.1 Pipes and ducts connected to the turbine casings are to be so designed that no excessive thrust loads or moments are applied to the gas turbines.

8.3.10.2 Platform gratings and fittings in way of the supports are to be so arranged that free expansion of casing can not be restricted.

Section 4 FITTINGS

8.4.1 *Overspeed protection*

8.4.1.1 An overspeed protective device is to be provided near the burners for each shaft of gas turbines to shut off the fuel supply automatically in order to prevent dangerous overspeed.

The overspeed protection values of main gas turbine and auxiliary gas turbine to drive an electric generator are to be 110% and 115% of the rated speed respectively.

8.4.2 *Speed governors*

8.4.2.1 Where a main propulsion gas turbine incorporates a reverse gear, controllable pitch propeller, electric transmission gear or other clutches, a speed governor independent of the overspeed protective device is to be fitted and is to be capable of controlling the speed of the power turbine without bringing the overspeed protective device into action when suddenly unloaded.

8.4.2.2 Where an auxiliary gas turbine is intended for driving an electric generator, a speed governor, independent of the overspeed protective device, is to be fitted and is to comply with the following requirements:

When the maximum step load is added or taken off, instantaneous frequency variation of the power grid is not to exceed ±10% of the rated frequency, and the recovery time for the engine speed (i.e. the time for the speed fluctuation ratio to return to ±1%) is not to exceed 5 s. When the rated load is suddenly taken off, instantaneous speed variation exceeding 10% of the rated speed is allowed provided this does not cause the intervention of the over-speed device as specified in 8.4.1 of this Chapter.

Under various load conditions from no-load to the rated load, variation of speed after being stable is not to exceed ±5% of the rated speed.

The permanent speed variations of A.C. generating sets intended for parallel operations are to be equal as far as possible.

8.4.3 *Low oil pressure protection*

8.4.3.1 Gas turbines are to be provided with low oil pressure protective devices capable of shutting off the fuel supply automatically when lubricating oil pressure is lower than the specified value.

8.4.4 *High gas temperature alarm*

8.4.4.1 Gas turbines are to be provided with high gas temperature alarms to give warning when the gas temperature at burner outlet exceeds the permissible value.

8.4.5 *Flame failure protection*

8.4.5.1 Gas turbines are to be provided with flame failure protective devices capable of shutting off the fuel supply automatically in the event of flame failure in the combustion chambers.

8.4.6 *High temperature alarm for bearings*

8.4.6.1 The bearings of gas turbines are to be provided with high temperature alarms to give warning when the lub oil is going up excessively.

8.4.7 *Hand trip gear*

8.4.7.1 Hand trip gear for shutting of the fuel supply in an emergency is to be provided at the manoeuvring platform of the gas turbines.

8.4.8 *Temperature control*

8.4.8.1 The following turbine services are to be fitted with automatic temperature controls so as to maintain steady state conditions throughout the normal operating range of the main gas turbine:
(1) lubricating oil supply;
(2) oil fuel supply (or automatic control of oil fuel viscosity as alternative);
(3) exhaust gas.

8.4.9 *Safety protection*

8.4.9.1 Main gas turbines are to be equipped with a quick closing device (shut-down device) which automatically shuts off the fuel supply to the turbines at least in case of:
(1) overspeed;
(2) unacceptable lubricating oil pressure drop;
(3) loss of flame during operation;
(4) excessive vibration;
(5) excessive axial displacement of each rotor (except for gas turbines with rolling bearings);
(6) excessive high temperature of exhaust gas;
(7) unacceptable lubricating oil pressure drop of reduction gear;
(8) excessive high vacuum pressure at the compressor inlet.

8.4.10 *Alarming devices*

8.4.10.1 Unless the FMEA required in item 8.1.6.2(3) proves otherwise, main gas turbines are to be provided with alarming and safeguards devices in accordance with the requirements of Table 8.4.10.1, they can be added or omitted, taking into account the result of FMEA specified in item 8.1.6.2(3).
8.4.10.2 Suitable alarms are to be operated by the activation of shutdown devices.

Alarms and Safeguards for Main Gas Turbines *Table 8.4.10.1*

Monitoring parameter	Alarm	Shutdown
Turbine speed	Overspeed	Overspeed
Lubricating oil pressure	Low*	Too low
Lubricating oil pressure of reduction gear	Low*	Too low
Differential pressure across lubricating oil filter	Large	
Lubricating oil temperature	High	
Oil fuel supply pressure	Low	
Oil fuel temperature	High	
Cooling medium temperature	High	
Bearing temperature	High	
Flame and ignition	Failure	Failure
Automatic starting	Failure	
Vibration	Large*	Too large
Axial displacement of rotor	Large	Large
Exhaust gas temperature	High*	Too high
Vacuum pressure at the compressor inlet	High*	Too high
Control system	Loss	

Note: Alarms marked with "*" are to be activated at the suitable setting points prior to arriving the critical condition for the activation of shutdown devices.

Section 5 TESTS AND TRIALS

8.5.1 *General requirements*

8.5.1.1 Turbines covered in 8.1.1.1 of this Chapter are to be subject to following tests and surveys.

8.5.2 *Material test and non-destructive test*

8.5.2.1 All components of turbines are to be subject to material test and non-destructive test according to the relevant requirements of 8.2.3 and 8.2.4 of this Chapter.

8.5.3 *Balance tests*

8.5.3.1 For compressors and gas turbines, all rotors as finished-bladed and complete with half-coupling are to be dynamically balanced.

8.5.4 *Hydraulic tests*

8.5.4.1 All casings (including compressors casings) are to be tested to a hydraulic pressure equal to 1.5 times the maximum working pressure. For test purposes, if necessary, the casings may be subdivided with temporary diaphragms for distribution of test pressure.

Where hydraulic tests can not be carried out, the manufacturers are to submit for approval, alternative proposals for determining the soundness of the component.

8.5.4.2 Heat exchangers and intercoolers are to be tested to a hydraulic pressure equal to 1.5 times the maximum working pressure on each side.

8.5.5 *Overspeed tests*

8.5.5.1 Before installation, all complete rotors of the gas turbines are at least to be tested at 115% of the rated speed for 5 min.

8.5.6 *Workshop trials*

8.5.6.1 Gas turbines are to be subject to a workshop trial, and the manufacturer's test program is to be submitted to ISC for approval.

8.5.7 *Shipboard trials*

8.5.7.1 After installation on board, each gas turbine, including all starting, control and safety systems, is to be operated to satisfactorily demonstrate its function.

8.5.7.2 Freedom of gas turbine from harmful vibration at speeds within the operating range is to be demonstrated.

8.5.7.3 The reversing characteristics of propulsion turbine plants are to be demonstrated.

8.5.7.4 The function of governor is to be demonstrated.

CHAPTER 9 DIESEL ENGINES

Section 1 GENERAL PROVISIONS

9.1.1 *Application*

9.1.1.1 The design, construction, installation as well as testing and trial of marine diesel engines, including main propulsion diesel engines， diesel engines for driving generators and other diesel engines related to classification, are to comply with the requirements of this Chapter.

9.1.1.2 The certification requirements and product survey of marine diesel engines are to comply with the requirements of Chapter 3, PART ONE of the Rules.

9.1.2 *Definitions*

9.1.2.1 For the purpose of this Chapter:

(1) A type of engine is defined by:

① bore and stroke;

② injection method (direct or indirect);

③ valve and injection operation (by cams or electronically controlled);

④ kind of fuel (liquid, dual-fuel, gaseous);

⑤ working cycle (4-stroke, 2-stroke);

⑥ turbo-charging system (pulsating or constant pressure);

⑦ the charging air cooling system (e.g. with or without intercooler);

⑧ cylinder arrangement (in-line or V)[①];

⑨ cylinder power, speed and cylinder pressures[②];

Notes:

① Requirements for type test of diesel engines with different cylinder arrangement are given in 9.10.2.3.

② Relevant provisions for cylinder power, speed and cylinder pressures are given in 9.10.2.4 and 9.10.2.5.

(2) Low-Speed Engines mean diesel engines having a rated speed of less than 300 rpm.

(3) Medium-Speed Engines mean diesel engines having a rated speed of 300 rpm and above, but less than 1,400 rpm.

(4) High-Speed Engines mean diesel engines having a rated speed of 1,400 rpm and above.

(5) The rated output is defined as the maximum continuous output developed by diesel engines (i.e. the maximum shaft power for which the machinery is to be classed) based on the ambient conditions specified in 1.2.1.3 or 1.2.1.4 of Chapter 1 of this PART. The rated speed is defined as the speed corresponding to the rated output.

9.1.3 *Overload power*

9.1.3.1 Main propulsion diesel engines，diesel engines for driving generators and other diesel engines related to classification are to be capable of running at 110% of the rated output.

9.1.4 *Astern*

9.1.4.1 Main engines are to be reversible except those coupled with variable pitch propellers, reversing gears or electric propulsion generators.

9.1.4.2 Main engines are to have sufficient astern capability to ensure proper control of the ship under normal conditions.

9.1.5 *Minimum steady speed*

9.1.5.1 Main engines are to have good performance at low speeds. In general, the minimum steady speed of diesel engines is to satisfy the following provisions:

(1) for low-speed engines, not more than 30% rated speed;

(2) for medium-speed engines: not more than 40% rated speed;

(3) for high-speed engines: not more than 45% rated speed.

9.1.6 *Manoeuvring*

9.1.6.1 The time required for reversing main engines is not to exceed 15 s. The time for reversal is defined as, when the main engine is running at the minimum steady speed, the time elapsed from the beginning of manoeuvring till starting of running in the opposite direction.

9.1.6.2 An index indicating the "Ahead" and "Astern" directions of the handle or the hand-wheel is to be fitted to the control station. As a common practice, for navigating the ship ahead, the handle is to be pushed forward, or the hand-wheel is to be turned clockwise.
9.1.6.3 An indicator showing the crankshaft rotational direction is to be fitted to the control station, but it may be dispensed with provided the tachometer is of a dual-rotation type.
9.1.6.4 For ships propelled by multiple engines geared on one shaft or more, a centralized control station for main engines is to be installed in the engine room, and is to be provided with interlocking device ensuring the correct operation sequence of main engines, clutches, etc. while manoeuvring. If the centralized control station is installed in the bridge, another control gear is to be provided in the engine room and is to be interlocked with that in the bridge.
9.1.6.5 Devices for quickly cutting off oil fuel supply or other effective arrangements for emergency stopping are to be provided near the main engine control station.

9.1.7 *Interlocking of turning gear*
9.1.7.1 For diesel engine arranged to be remotely controlled or automatically started, a safety interlocking device is to be fitted between the turning gear and the starting arrangement of the main engine in order to prevent the diesel engine being started when the turning gear is under engagement condition.
9.1.7.2 For diesel engine not arranged to be remotely controlled or automatically started, instructions for safety operations or warning notice are at least to be provided in order to prevent the diesel engine being started by mistake when the turning gear is under engagement condition. The warning notice is to specify that diesel engine is not to be started when the turning gear is under engagement condition.

9.1.8 *Vibration and alignment*
9.1.8.1 The vibration and alignment of marine diesel engine shafting are to comply with the relevant requirements as specified in Chapter 12 of this PART.

9.1.9 *Gas fuel engines*
9.1.9.1 In addition to the relevant provisions of this Chapter, gas fuel engines are to comply with the applicable requirements of Appendix 1[①] of this Chapter, ISC Rules for Ships Using Natural Gas Fuels and ISC Guidelines for Design and Installation of Gas Fuel Engine Systems of Liquefied Gas Carriers.

9.1.10 *Electrically controlled diesel engines*
9.1.10.1 Electrically controlled diesel engines are to comply with the relevant requirements of Appendix 2 of this Chapter.

9.1.11 Turbochargers[②]
9.1.11.1 The turbochargers are to be designed to operate under conditions given in 1.2.1, Chapter 1 of this PART. The component lifetime and the alarm level for speed are to be based on 45℃ air inlet temperature.
9.1.11.2 Turbochargers are categorized in three groups depending on served power by cylinder groups (e.g. for a V-engine with one turbocharger for each bank, the size is half of the total engine rated power) with:
(1) Category A: ≤ 1,000 kW;

---

① (1) Appendix 1 applies to gas fuel engines for which the date of an application for type approval certification is dated on or after 1 July 2019.
(2) The "date of application for type approval" is the date of documents accepted by ISC as request for type approval certification of a new engine type or of an engine type that has undergone substantive modifications in respect of the one previously type approved, or for renewal of an expired type approval certificate.
(3) Engines with an existing type approval on 1 July 2019 are not required to be re-type approved in accordance with the new requirements until the current type approval becomes invalid. For the purpose of certification of these engines, the current type approval and related submitted documentation will be accepted.

② (1) The requirements of 9.1.11, 9.1.12.3, 9.6.2, 9.6.6.2, 9.6.10 and 9.6.11 apply to turbochargers with the date of an application for certification of the new turbocharger type or of a turbocharger type that has undergone substantive modifications in respect of the one previously type approved, or for renewal of an expired type approval certificate on or after 1 January 2023. Turbochargers with an existing type approval on 1 January 2023 are not required to be re-type approved in accordance with the requirement until the current Type Approval reaches its expiry date. The requirements of 9.6.12 apply to turbochargers with the date of application for certification of an individual turbocharger on or after 1 January 2023.
(2) The "date of application for certification" is the date of whatever document ISC requires/accepts as an application or request for certification of a new turbocharger type or of a turbocharger type that has undergone substantive modifications in respect of the one previously type approved, or for renewal of an expired type approval certificate.

(2) Category B: > 1,000 kW and ≤ 2,500 kW;
(3) Category C: > 2,500 kW.

9.1.11.3 The requirements for turbochargers with regard to design, approval, type testing and certification escalate with the size of the turbochargers. For details, see Section 6 of this Chapter.

9.1.11.4 Turbochargers are to be type approved, either separately or as a part of an engine.

9.1.11.5 The requirements relating to turbochargers in this Chapter are written for exhaust gas driven turbochargers, but apply in principle also for engine driven chargers.

9.1.12 *Plans and documents*

9.1.12.1 The following engine plans and documents are to be submitted for approval:

No.	Item
1	Bedplate and crankcase of welded design, with welding details and welding instructions[1,2]
2	Thrust bearing bedplate of welded design, with welding details and welding instructions[1]
3	Bedplate/oil sump welding drawings[1]
4	Frame/framebox/gearbox of welded design, with welding details and instructions[1,2]
5	Frame/framebox/gearbox, with welding drawings[1,2]
6	Crankshaft, details, each cylinder No.
7	Crankshaft, assembly, each cylinder No.
8	Crankshaft calculations (for each cylinder configuration) according to Appendix 3 of this Chapter
9	Thrust shaft or intermediate shaft (if integral with engine)
10	Shaft coupling bolts
11	Material specifications of main parts (see Table 9.2.2.1) with information on non-destructive material tests and pressure tests[3]
12	Schematic layout or other equivalent documents on the engine of starting air system, fuel oil system, lubricating oil system, cooling water system, hydraulic system (including hydraulic system for valve lift), control and safety system
13	Shielding of high pressure fuel pipes, assembly[4]
14	Construction and strength of accumulators (for electronically controlled engine)
15	Arrangement and details of the crankcase explosion relief valve (see 9.7.4)[5]
16	Calculation results for crankcase explosion relief valves (see 9.7.4)
17	Details of the type test program and the type test report[7]
18	High pressure parts for fuel oil injection system[6]
19	Oil mist detection and/or alternative alarm arrangements (see 9.7.6 and 9.7.7)
20	Details of mechanical joints of piping systems (see 2.5.3, Chapter 2 of this PART)
21	Documentation verifying compliance with inclination limits (see 1.2.1, Chapter 1 of this PART)
22	Documents as required in Section 6, Chapter 2, PART SEVEN of the Rules, as applicable

Notes:
1. For approval of materials and weld procedure specifications. The weld procedure specification is to include details of pre and post weld heat treatment, weld consumables and fit-up conditions.
2. For each cylinder for which dimensions and details differ.
3. For comparison with rules requirements for material, NDT and pressure testing as applicable.
4. All engines.
5. Only for engines of a cylinder diameter of 200 mm or more or a crankcase volume of 0.6 m^3 or more.
6. The documentation to contain specifications for pressures, pipe dimensions and materials.
7. The type test program is to be submitted before the type test, and the type test report may be submitted after the conclusion of the type test.

9.1.12.2 The following engine plans and documents are to be submitted for information:

No.	Item
1	Engine particulars (e.g. Data sheet with general engine information (see Annex 3 to Appendix 5 of this Chapter), Project Guide, Marine Installation Manual)
2	Engine cross section
3	Engine longitudinal section
4	Bedplate and crankcase of cast design
5	Thrust bearing assembly[1]
6	Frame/framebox/gearbox of cast design[2]
7	Tie rod

8	Connecting rod
9	Connecting rod, assembly[3]
10	Crosshead, assembly[3]
11	Piston rod, assembly[3]
12	Piston, assembly[3]
13	Cylinder jacket/ block of cast design[2]
14	Cylinder cover, assembly[3]
15	Cylinder liner
16	Counterweights (if not integral with crankshaft), including fastening
17	Camshaft drive, assembly[3]
18	Flywheel
19	Fuel oil injection pump
20	Shielding and insulation of exhaust pipes and other parts of high temperature which may be impinged as a result of a fuel system failure, assembly
21	For electronically controlled engines, construction and arrangement of control valves, high-pressure pumps and drive for high pressure pumps
22	Operation and service manuals[4]
23	FMEA (for engine control system)[5]
24	Production specifications for castings and welding (sequence)
25	Evidence of quality control system for engine design and in service maintenance
26	Quality requirements for engine production
27	Type approval certification for environmental tests, control components of electrical system[6]
28	Fatigue analysis of high pressure fuel oil piping and hydraulic oil piping (where applicable)
29	Other plans and documents as deemed necessary by ISC

Notes:

1. If integral with engine and not integrated in the bedplate.
2. Only for one cylinder or one cylinder configuration.
3. Including identification (e.g. drawing number) of components.
4. Operation and service manuals are to contain maintenance requirements (servicing and repair) including details of any special tools and gauges that are to be used with their fitting/settings together with any test requirements on completion of maintenance.
5. Where engines rely on hydraulic, pneumatic or electronic control of fuel injection and/or valves, a failure mode and effects analysis (FMEA) is to be submitted to demonstrate that failure of the control system will not result in the operation of the engine being degraded beyond acceptable performance criteria for the engine.
6. Tests are to demonstrate the ability of the control, protection and safety equipment to function as intended under the specified testing conditions per ISC Guidelines for Type Approval Test of Electric and Electronic Products.

9.1.12.3 For turbochargers, the following plans and documents are to be submitted for approval:

(1) Category A:

① Containment test report;

② Cross sectional drawing with principal dimensions and names of components;

③ Test program.

(2) Category B and C:

① Cross sectional drawing with principal dimensions and materials of housing components for containment evaluation;

② Documentation of containment in the event of disc fracture (see 9.6.10);

③ Operational data and limitations, including maximum permissible operating speed (rpm), alarm level for overspeed, maximum permissible exhaust gas temperature before turbine, alarm level for exhaust gas temperature before turbine, minimum lubrication oil inlet pressure, lubrication oil inlet pressure low alarm set point, maximum lubrication oil outlet temperature, lubrication oil outlet temperature high alarm set point, maximum permissible vibration levels (i.e. self- and externally generated vibration);

Note: Alarm levels may be equal to permissible limits but are not to be reached when operating the engine at 110% power or at any approved intermittent overload beyond the 110%.

④ Arrangement of lubrication system, all variants within a range;

⑤ Type test reports;

⑥ Test program.

(3) In addition to the provisions of (2) above, the following plans and documents for category C turbochargers are to be submitted:

① Drawings of the housing and rotating parts including details of blade fixing;
② Material specifications (chemical composition and mechanical properties) of all parts mentioned above;
③ Welding details and welding procedure of above mentioned parts, if applicable;
④ Documentation* of safe torque transmission when the disc is connected to the shaft by an interference fit, see 9.6.6.2;
⑤ Information on expected lifespan, considering creep, low cycle fatigue and high cycle fatigue;
⑥ Operation and maintenance manuals*.

Note: * Applicable to two sizes in a generic range of turbochargers.

Section 2 INSPECTION, TEST AND CERTIFICATION OF DIESEL ENGINE PARTS

9.2.1 *General requirements*

9.2.1.1 The engine manufacturer is to have a quality control system that is suitable for the actual engine types. The quality control system is also to apply to any sub-suppliers. ISC reserves the right to review the system or parts thereof.

9.2.1.2 Materials and components are to be produced in compliance with all the applicable production and quality instructions specified by the engine manufacturer.

9.2.1.3 Certain parts are to be verified and documented by means of ISC Marine Product Certificate (C), Manufacturer's document (W) or Test Report (TR). For the definitions of ISC Marine Product Certificate (C), Manufacturer's document (W) or Test Report (TR), see Chapter 3, PART ONE of the Rules.

9.2.1.4 The documents above are used for product documentation as well as for documentation of single inspections such as crack detection, dimensional check, etc. If agreed to by ISC, the documentation of single tests and inspections may also be arranged by filling in results on a control sheet following the component through the production.

9.2.1.5 The TR and W issued by the manufacturer are to be submitted to ISC for review to ensure compliance with the agreed or approved specifications. ISC Marine Product certificate (C) means that the Surveyor also witnesses the testing, batch or individual, unless Alternative Certification Scheme (ACS) provides other arrangements.

9.2.1.6 The manufacturer is not exempted from responsibility for any relevant tests and inspections of those parts for which documentation is not explicitly requested by ISC. The manufacturing works process and equipment is to be set up and maintained in such a way that all materials and components can be consistently produced to the required standard. This includes production and assembly lines, machining units, special tools and devices, assembly and testing rigs as well as all lifting and transportation devices.

9.2.1.7 The extent of parts to be documented depends on the type of engine, engine size and criticality of the part. Requirements for inspection, test and documentation of diesel engine parts are listed in Table 9.2.2.1.

9.2.1.8 For components and materials not specified in Table 9.2.2.1, consideration will be given by ISC upon full details being submitted and reviewed.

9.2.1.9 Symbols used in Table 9.2.2.1 are listed below.

Symbol	Description
CC	Chemical composition
CH	Crosshead engines
D	Cylinder bore diameter (mm)
M	Mechanical properties
MT	Magnetic particle testing
PT	Dye penetration testing
UT	Ultrasonic testing
VT	Visual examination of accessible surfaces by the Surveyor

9.2.2 *Inspection, test and certification*

9.2.2.1 Diesel engine parts are to be subject to material test, NDT, hydraulic test, dimensional inspection and visual examination as given in Table 9.2.2.1.

9.2.2.2 Turbochargers are to be subject to inspection, test and certification in accordance with the relevant requirements of Section 6 of this Chapter.

9.2.2.3 Crankcase explosion relief valves are to be subject to inspection, test and certification in accordance with the requirements of 9.7.4 of this Chapter.

9.2.2.4 Oil mist detection system is to be subject to inspection, test and certification in accordance with the requirements of 9.7.6 and 9.7.7 of this Chapter.

9.2.2.5 Speed governor and overspeed protection device are to be subject to inspection and test in accordance with the requirements of 9.7.8, 9.7.9 and 9.7.10 of this Chapter.

9.2.2.6 Diesel engine control, alarm and safety protection system (including computer system) are to be subject to inspection and test in accordance with the relevant requirements of PART SEVEN of the Rules.

9.2.2.7 Material test and non-destructive testing are to be carried out in accordance with the relevant requirements of ISC Rules for Materials and Welding.

9.2.2.8 Hydraulic testing is applied on the water/oil side of the component. Items are to be tested by hydraulic pressure at the pressure equal to 1.5 times the maximum working pressure. High pressure parts of the fuel injection system are to be tested by hydraulic pressure at the pressure equal to 1.5 times the maximum working pressure or maximum working pressure plus 300 bar, whichever is the less. Where design or testing features may require modification of these test requirements, relevant documents are to be submitted for confirmation.

Summary of inspection, test and certification of diesel engine parts *Table 9.2.2.1*

Item	Parts [5]	Material properties [1]	Non-destructive examination [2]	Hydraulic testing	Dimensional inspection (including surface condition)	Visual inspection (surveyor)	Applicable to engines
1	Welded bedplate	CC+M	UT+MT/PT			VT(fit-up and post-welding)	All
2	Bearing transverse girders (cast steel)	CC+M	UT+MT/PT			VT	All
3	Welded frame box	CC+M	UT+MT/PT			VT(fit-up and post-welding)	All
4	Cylinder block (cast iron)			X[4]			>400 kW/cyl
5	Welded cylinder frames	CC+M	UT+MT/PT			VT(fit-up and post-welding)	CH
6	Engine block (grey cast iron)			X[4]			>400 kW/cyl
7	Engine block (nodular graphite cast iron)	M		X[4]			>400 kW/cyl
8	Cylinder liner	CC+M		X[4]			D>300mm
9	Cylinder head (cast iron)			X			D>300mm
10	Cylinder head (cast steel)	CC+M	UT+MT/PT	X		VT	D>300mm
11	Forged cylinder head	CC+M	UT+MT/PT	X		VT	D>300mm
12	Piston crown (cast steel)	CC+M	UT+MT/PT			VT	D>400mm
13	Forged piston crown	CC+M	UT+MT/PT			VT	D>400mm
14	Crankshaft: made in one piece	CC+M	UT+MT/PT		X	VT (random, of fillets and oil bores)	All
15	Semi-built crankshaft (Crank throw, forged main journal and journals with flange)	CC+M	UT+MT/PT		X	VT (random, of fillets and shrink fittings)	All
16	Exhaust gas valve cage			X			CH
17	Piston rod	CC+M	UT+MT/PT			VT (random)	D>400mm CH
18	Cross head	CC+M	UT+MT/PT			VT (random)	CH
19	Connecting rod with cap	CC+M	UT+MT/PT		X	VT (random, of all surfaces, in particular those shot peened)	All
20	Coupling bolts for crankshaft	CC+M	UT+MT/PT		X	VT (random, of interference fit)	All

Item	Parts [5)]	Material properties [1)]	Non-destructive examination [2)]	Hydraulic testing	Dimensional inspection (including surface condition)	Visual inspection (surveyor)	Applicable to engines
21	Bolts and studs for main bearings and cylinder heads	CC+M	UT+MT/PT				D>300mm
22	Bolts and studs for connecting rods	CC+M	UT+MT/PT		X (thread making)		D>300mm
23	Tie rod	CC+M	UT+MT/PT		X (thread making)	VT (random)	CH
24	High pressure fuel injection pump body	CC+M		X			All
25	High pressure fuel injection valves (only for not autofretted)			X			All
26	High pressure fuel injection pipes including common fuel rail	CC+M		X for those that are not autofretted			All
27	High pressure common servo oil system	CC+M		X			All
28	Cooler, both sides [3)]	CC+M		X			D>300mm
29	Accumulator	CC+M		X			All engines with accumulators with a capacity of >0.5 l
30	Piping, pumps, actuators, etc. for hydraulic drive of valves, if applicable	CC+M		X			>800 kW/cyl
31	Engine driven pumps (oil, water, fuel, bilge) other than pumps referred to in item 24 and 30			X			>800 kW/cyl
32	Bearings for main, crosshead, and crankpin	CC	UT (full contact between basic material and bearing metal)		X		>800 kW/cyl

Notes:

(1) Material properties include chemical composition and mechanical properties, and also surface treatment such as surface hardening (hardness, depth and extent), peening and rolling (extent and applied force).

(2) Non-destructive examination means e.g. ultrasonic testing, crack detection by MT or PT. When certain NDE method on the finished component is impractical (for example UT for items 10/11), the NDE method can be performed at earlier appropriate stages in the production of the component, see 3.1.5.2, PART ONE of the Rules.

(3) Charge air coolers need only be tested on the water side.

(4) Hydraulic testing is also required for those parts filled with cooling water and having the function of containing the water which is in contact with the cylinder or cylinder liner.

(5) Material certification requirements for pumps and piping components are dependent on the operating pressure and temperature. The certification requirements for relevant components are to comply with the requirements of Chapter 3, PART ONE of the Rules.

Section 3 DESIGN AND CONSTRUCTION

9.3.1 *Design*

9.3.1.1 Design and construction of diesel engines are to comply with relevant requirements relating to ambient condition, properties and availability specified in Section 2, Chapter 1 of this PART.

9.3.1.2 Fatigue strength calibration or diameter calibration may be adopted in calculating crankshafts of

diesel engines. For details, see Appendix 3 of this Chapter.

9.3.2 *Materials*

9.3.2.1 The specified tensile strength of forgings and castings for crankshafts is in general to be selected within the following limits, and the materials used are to comply with the relevant requirements contained in ISC Rules for Materials and Welding:

(1) carbon and carbon-manganese steel 400 to 600 N/mm^2;

(2) alloy steel 600 to 1,000 N/mm^2;

(3) nodular graphite cast iron 490 to 780 N/mm^2.

9.3.2.2 Where it is proposed to use alloy steel forgings for crankshafts, details of the chemical composition, heat treatment and mechanical properties are to be submitted for approval.

9.3.3 *Structure*

9.3.3.1 Frames and bedplates of diesel engines are to be stress-relieved. Where valid documentation and evidence are provided by the manufacturer or the designer, the stress-relieved treatment is unnecessary. In the case of welded structure, they are to meet, furthermore, the relevant requirements in ISC Rules for Materials and Welding.

Section 4 PIPING SYSTEMS

9.4.1 *Lubricating oil systems*

9.4.1.1 The lubricating oil systems of diesel engines are to be so designed and installed as to maintain operation when the ship is under a list or trim up to that as given in 1.2.1.1 of Chapter 1 of this PART.

9.4.1.2 Diesel engines greater than 37 kW are to be provided with an audible and visible alarm device giving an indication of failure of lubricating oil systems.

9.4.1.3 Lubricating oil drain pipes from the engine sump to the drain tank are to be submerged at their outlet ends.

9.4.1.4 In addition, the lubricating oil systems are to comply with the relevant requirements of Section 6, Chapter 4 of this PART.

9.4.2 *Cooling water systems*

9.4.2.1 For large low-speed diesel engine having oil-cooled or water-cooled pistons, a thermometer and a device for observing the circulation of cooling oil or cooling water are to be fitted to each outlet pipe led from the inside of the piston. If there is no outlet pipe led from the inside of the piston, other means of arrangement may be adopted.

9.4.2.2 Cooling water systems of diesel engines are to be provided with alarm devices for indicating the excess temperature.

9.4.2.3 In addition, the cooling water systems are to comply with the relevant requirements of Section 5, Chapter 4 of this PART.

9.4.3 *Oil fuel systems*

9.4.3.1 For cargo ships of 500 gross tonnage and over and all passenger ships, high-pressure fuel delivery lines are to meet the relevant requirements of PART SIX of the Rules.

For cargo ships of less than 500 gross tonnage, where the cylinder bore of main and auxiliary diesel engines is 250 mm and above, the fuel injection piping is to be effectively secured and shielded so as to prevent oil fuel or oil fuel mist from reaching a source of ignition on the engine or its surroundings. Suitable drainage arrangements are to be made for draining any oil fuel leakage.

9.4.3.2 Where, on V-type engines, the fuel system is located between the rows of cylinders, suitable shielding and drainage ducts for leaking fuel are to be provided.

9.4.3.3 Leaking fuel is to be safely drained away at zero excess pressure. Care is to be taken to ensure that leaking fuel cannot become mixed with the engine lubricating oil.

9.4.3.4 Where the engine is installed on elastic mountings, the approved flexible joints are to be fitted in way of connection between the diesel engine and fuel oil supply pipes. The flexible joints are to comply with relevant requirements of Section 5, Chapter 2 of this PART.

9.4.3.5 In addition, the oil fuel systems are to comply with the relevant requirements of Section 2, Chapter 4 of this PART.

9.4.4 *Exhaust systems*

9.4.4.1 An instrument for measuring the exhaust gas temperature is to be fitted to each cylinder of diesel engines with cylinder bore 200 mm and over.

9.4.4.2 The exhaust pipes of diesel engines are to be provided with effective silencers or other equivalent silencing measures.

9.4.4.3 Each diesel engine is to have a separate exhaust pipe to prevent the backflow of the exhausts. Where the exhausts of two or more engines are led to a common silencer or exhaust gas-heated boiler or economizer, an isolating device is to be provided in each exhaust pipe.

9.4.4.4 Where the exhaust is led overboard near the waterline, means are to be provided to prevent water from being siphoned back to the diesel engine.

9.4.4.5 For alternatively fired furnaces of boilers using exhaust gases and oil fuel, the exhaust gas inlet pipe is to be provided with an isolating device and interlocking arrangements whereby oil fuel can only be supplied to the burners when the isolating device is closed to the boiler.

9.4.4.6 In addition, the exhaust systems are to comply with the relevant requirements of Section 10, Chapter 4 of this PART.

9.4.5 *Starting air systems*

9.4.5.1 The air discharge pipe from the compressors is to be led direct to the starting air receivers. Provision is to be made for intercepting and draining oil and water in the air discharge for which purpose a separator or filter is to be fitted in the discharge pipe between compressors and receivers.

9.4.5.2 The starting air pipe system from receivers to main and auxiliary engines is to be entirely separate from the compressor discharge pipe system.

9.4.5.3 The starting air piping system is to be protected against the effects of explosions due to the improper function of the starting valve by providing an isolating non-return valve or equivalent at the starting air supply to each engine.

9.4.5.4 In diesel engines having cylinders exceeding 230 mm, bursting discs or flame arresters or other equivalent means are to be fitted in the starting air systems, such devices are to be fitted at the starting valves on each cylinder for direct reversing engines and at the supply inlet to the starting air manifold for non-reversing engines.

Section 5 STARTING ARRANGEMENTS

9.5.1 *Mechanical starting arrangements*

9.5.1.1 The arrangement for air starting is to be such that the necessary air for the first charge can be produced on board without external aid.

9.5.1.2 Where the main engine is arranged for starting by compressed air, two or more air compressors are to be fitted. At least one of the compressors is to be driven independent of the main propulsion unit and is to have the capacity not less than 50% of the total required.

The total capacity of air compressors is to be sufficient to supply within one hour the quantity of air needed to satisfy 9.5.1.6 by charging the receivers from atmospheric pressure. The capacity is to be approximately equally divided between the number of compressors fitted, excluding an emergency compressor which may be installed to satisfy the requirements of 9.5.1.1.

9.5.1.3 Pressure gauges and safety valves are to be fitted to air compressors. The safety valves are to be set at a pressure not more than 1.1 times the working pressure. Casings of the cooling water space of compressed air coolers are to be provided with relief valves or bursting discs.

9.5.1.4 Relief valves are to be fitted to the crankcase of air compressors when the crankcase has a volume exceeding 0.6 m^3.

9.5.1.5 The design and construction of air receivers are to comply with the relevant requirements contained in Section 4 and Appendix 4, Chapter 6 of this PART.

9.5.1.6 Where the main engines are arranged for starting by compressed air, at least two starting air receivers of about equal capacity are to be fitted, which can be used independently. The total capacity of air receivers is to be sufficient to provide, without their being replenished, not less than 12 consecutive starts alternating between ahead and astern of each main engine of the reversible type, and not less than 6 starts of each main non-reversible type engine connected to a controllable pitch propeller or other device enabling the start without opposite torque. When other consumers such as auxiliary engines starting systems, control systems, whistle, etc., are to be connected to starting air receivers, their air consumption is also to be taken into account. Regardless of the above, for multi-engine installations the number of starts required for each engine may be reduced to 3 times, the total number of starts is not to be less than 12 times, but

unnecessarily exceed 18 times.
9.5.1.7 The air receivers are to be so fitted with drain arrangement as to permit effective drainage when the ship is under normal inclination conditions.

9.5.2 *Electric starting installations*

9.5.2.1 Where the main engine is arranged for electric starting, two separate batteries are to be fitted. The arrangement is to be such that the batteries cannot be connected in parallel. Each battery is to be capable of starting the main engine when in cold and ready to start conditions. The combined capacity of the batteries is to be sufficient without recharging to provide within 30 min the number of starts of main engines as required in 9.5.1.6 of this Section in case of air starting.
9.5.2.2 Electric starting arrangements for auxiliary engines are to have two separate batteries or may be supplied by separate circuits from the main engine batteries when such are provided. In the case of a single auxiliary engine only one battery may be required. The capacity of the batteries for starting the auxiliary engines is to be sufficient for at least three starts for each engine.
9.5.2.3 The starting batteries are to be used for starting and the engines own monitoring purposes only. Provisions are to be made to maintain continuously the stored energy at all times.

9.5.3 *Starting arrangements for emergency generating sets*

9.5.3.1 The prime mover of emergency generating sets is to be capable of being started in cold condition at a temperature of 0℃. If this is impracticable, or if lower temperatures are likely to be encountered, an accessory heating arrangement may be fitted so as to ensure low-temperature starting of the emergency generating sets.
9.5.3.2 Each emergency generating set arranged to be automatically started is to be equipped with starting devices with a stored energy capability of at least three consecutive starts. The source of stored energy is to be protected to preclude critical depletion by the automatic starting system, unless a second independent means of starting is provided. In addition, a second source of energy is to be provided for an additional three starts within 30 min unless manual starting can be demonstrated to be effective.
9.5.3.3 The stored energy is to be maintained at all times as follows:
(1) Electrical and hydraulic starting systems are to be maintained from the emergency switchboard.
(2) Compressed air starting systems may be maintained by the main or auxiliary compressed air receivers through a suitable non-return valve or by an emergency air compressor which, if, electrically driven, is supplied from the emergency switchboard.
(3) All of these starting, charging and energy storing devices are to be located in the emergency generator space; these devices are not to be used for any purpose other than the operation of the emergency generating set. This does not preclude the supply to the air receiver of the emergency generating set from the main or auxiliary compressed air system through the non-return valve fitted in the emergency generator space.
9.5.3.4 Where automatic starting is not required, manual starting is permissible, such as manual cranking, inertia starts, manually charged hydraulic accumulators, or powder charge cartridges, where they can be demonstrated as being effective.
When manual starting is not practicable, the requirements of 9.5.3.2 and 9.5.3.3 are to be complied with except that starting may be manually initiated.
9.5.3.5 Where the emergency generating sets are provided with electronic speed governors (or other auxiliary facilities which are only able to start after being supplied with electric power), two sets of power supply which are independent from each other are to be provided.
9.5.3.6 The emergency generator used to restore operation from the dead ship condition is to comply with the provisions of 1.2.6, Chapter 1 of this PART.

Section 6 SCAVENGING AND SUPERCHARGING ARRANGEMENTS

9.6.1 *Lubricating oil systems*

9.6.1.1 The lubricating oil system of exhaust gas turbochargers may be separate from, or in common with, that of the main engine. If lubricating oil pumps are not directly driven by turbochargers, an independent standby lubricating oil pump is to be provided. And in addition, large low-speed diesel engines are to be provided with lubricating oil gravity tanks for emergency. Lubricating oil systems are to be arranged according to the requirements of 1.2.1.1 of this PART.

9.6.2 *Alarm and monitoring*

9.6.2.1 For all turbochargers of Categories B and C, indications and alarms as listed in Table 9.6.2.1 are required.
9.6.2.2 Indications may be provided at either local or remote locations.

Requirements for alarm and indication of turbochargers of categories B and C

Table 9.6.2.1

Pos.	Monitored Parameters	Category of Turbochargers				Remark
		B		C		
		Alarm	Indication	Alarm	Indication	
1	Speed	High (4)	X (4)	High (4)	X (4)	
2	Exhaust gas at each turbocharger inlet, temperature	high (1)	X (1)	high	X	High temp. alarms for each cylinder at engine is acceptable (2)
3	Lub. oil at turbocharger outlet, temperature			high	X	If not forced system, oil temperature near bearings
4	Lub. oil at turbocharger inlet, pressure	low	X	low	X	Only for forced lubrication systems (3)

Notes:
(1) For Category B turbochargers, the exhaust gas temperature may be alternatively monitored at the turbocharger outlet, provided that the alarm level is set to a safe level for the turbine and that correlation between inlet and outlet temperatures is substantiated.
(2) Alarm and indication of the exhaust gas temperature at turbocharger inlet may be waived if alarm and indication for individual exhaust gas temperature is provided for each cylinder and the alarm level is set to a value safe for the turbocharger.
(3) Separate sensors are to be provided if the lubrication oil system of the turbocharger is not integrated with the lubrication oil system of the diesel engine or if it is separated by a throttle or pressure reduction valve from the diesel engine lubrication oil system.
(4) On turbocharging systems where turbochargers are activated sequentially, speed monitoring is not required for the turbocharger(s) being activated last in the sequence, provided all turbochargers share the same intake air filter and they are not fitted with waste gates.

9.6.3 *Air filters and silencers*
9.6.3.1 Turbochargers are to be fitted with inlet air filters and silencers.

9.6.4 *Rotor shaft locking devices*
9.6.4.1 Turbocharger rotor shafts are to be provided with locking devices. If not, by-pass connections or other suitable devices are to be fitted to the pipes before and after the turbines to ensure the normal operation of main engines in case of turbocharger breakdown.

9.6.5 *Critical speeds*
9.6.5.1 Critical speeds of the turbocharger rotor are to be determined by calculation. In the case of rigid rotor shafts, critical speeds are not to be less than 1.3 times the rated speed.

9.6.6 *Rotors and rotor shafts*
9.6.6.1 Where rotor shafts are of welded construction, they are to meet the relevant requirements in ISC Rules for Materials and Welding.
9.6.6.2 For turbochargers of category C, in cases where the disc is connected to the shaft with interference fit, calculations is to substantiate safe torque transmission during all relevant operating conditions such as maximum speed, maximum torque and maximum temperature gradient combined with minimum shrinkage amount.
9.6.6.3 After assembly, rotors are to be dynamically balanced.

9.6.7 *Protection*
9.6.7.1 For two-stroke loop-scavenged and cross-scavenged diesel engines, grids or other suitable devices are to be fitted before turbine nozzles to prevent broken piston rings from entering into the turbine casings.
9.6.7.2 It is undesirable to connect vent pipes of crankcase with turbocharger inlets. Otherwise, effective oil vapor separating devices are to be fitted before the turbocharger inlets.

9.6.8 *Emergency blowers*
9.6.8.1 Two-stroke turbocharged diesel engines not equipped with scavenge pumps are to be provided with independent emergency blowers, except that the scavenging air systems arranged in series are available.

9.6.9 *Relief valves of scavenging air receivers and fire extinguishing devices*

9.6.9.1 Scavenging air receivers of two-stroke diesel engines are to be fitted with relief valves as well as devices for removing dirty oil and condensate. Relief valves are to be set generally at a pressure not more than 1.1 times the maximum scavenging air pressure.

9.6.9.2 Crosshead type engine scavenge spaces in open connection with cylinders are to be provided with independent fire extinguishing arrangements which are to be independent of the fire extinguishing system of the engine room.

9.6.10 *Containment*

9.6.10.1 Turbochargers are to fulfil containment in the event of a rotor burst. This means that at a rotor burst no part may penetrate the casing of the turbocharger or escape through the air intake. For documentation purposes (test/calculation), it is to be assumed that the discs disintegrate in the worst possible way.

9.6.10.2 For category B and C, containment is to be documented by testing. Fulfilment of this requirement can be awarded to a generic range of turbochargers based on testing of one specific unit. Testing of a large unit is preferred as this is considered conservative for all smaller units in the generic range. In any case, it must be documented (e.g. by calculation) that the selected test unit really is representative for the whole generic range.

9.6.10.3 The minimum test speeds, relative to the maximum permissible operating speed, are:

— for the compressor: 120%;

— for the turbine: 140% or the natural burst speed, whichever is lower.

9.6.10.4 Containment tests are to be performed at a temperature which is not lower than the maximum allowable temperature of the turbocharger to be specified by the manufacturer.

9.6.10.5 Manufacturers are to determine whether cases more critical than those defined in 9.6.10.3 and 9.6.10.4 exist with respect to containment safety. Where such a case is identified, evidence of containment safety is also to be provided for that case.

9.6.10.6 A numerical analysis simulation such as Finite Element Method (FEM) of sufficient containment integrity of the casing based on calculations by means of a simulation model may be accepted in lieu of the practical containment test, provided that:

(1) the numerical simulation model has been tested and its suitability/accuracy has been proven by direct comparison between calculation results and the practical containment test for a reference application (reference containment test). This test is to be performed at least once by the manufacturer for acceptance of the numerical simulation method in lieu of tests;

(2) the corresponding numerical simulation for the containment is performed for the same speeds as specified for the containment test;

(3) material properties for high-speed deformations are to be applied in the numeric simulation. The correlation between normal properties and the properties at the pertinent deformation speed are to be substantiated;

(4) the design of the turbocharger regarding geometry and kinematics is similar to the turbocharger that was used for the reference containment test. In general, totally new designs will call for a new reference containment test.

Note: A generic range means a series of turbocharger which are of the same design, but scaled to each other.

9.6.10.7 In cases where a totally new design is adopted for a turbocharger for which an application for type approval certification has been requested, new reference containment tests are to be performed.

Note: Totally new design means the principal differences between a new turbocharger and previous ones are related to geometry and kinematics. The turbochargers are to be regarded as having a totally new design if the structure and/or material of the turbocharger casings are changed, or any of, but not limited to, the following items is changed from the previous design.

(1) Maximum permissible exhaust gas temperature;
(2) Number of bearings;
(3) Number of turbine blades;
(4) Number of turbine wheels and/or compressor wheels;
(5) Direction of inlet air and/or exhaust gas (e.g., axial flow orientation, radial flow orientation);
(6) Type of the turbocharger drive (e.g., axial turbine type, radial turbine type, mixed flow turbine type).

9.6.11 *Type testing*

9.6.11.1 Type testing is applicable to categories B and C. The type test for a generic range of turbochargers may be carried out either on an engine (for which the turbocharger is foreseen) or in a test rig.

9.6.11.2 Turbochargers for the low, medium, and high-speed engines are to be subjected to at least 500 load cycles at the limits of operation. This test may be waived if the turbocharger together with the engine is subjected to this kind of low cycle testing, see Appendix 4 of this Chapter.
9.6.11.3 The suitability of the turbocharger for such kind of operation is to be preliminarily stated by the manufacturer.
9.6.11.4 The rotor vibration characteristics are to be measured and recorded in order to identify possible sub-synchronous vibrations and resonances.
9.6.11.5 The type test is to be completed by a hot running test at maximum permissible speed combined with maximum permissible temperature for at least one hour. After this test, the turbocharger is to be opened for examination, with focus on possible rubbing and the bearing conditions.
9.6.11.6 The extent of the surveyor's presence during the various parts of the type tests is left to the discretion of each Society.

9.6.12 *Certification*
9.6.12.1 The manufacturer is to adhere to a quality system designed to ensure that the designer's specifications are met, and that manufacturing is in accordance with the approved drawings.
9.6.12.2 For category C, this is to be verified by means of periodic product audits of Alternative Certification Scheme (ACS, see Section 10, Chapter 3, PART ONE of the Rules).
9.6.12.3 These audits are to focus on:
(1) chemical composition of material for the rotating parts;
(2) mechanical properties of the material of a representative specimen for the rotating parts and the casing;
(3) UT and crack detection of rotating parts, or other non-destructive testing as applicable;
(4) dimensional inspection of rotating parts;
(5) rotor balancing;
(6) hydraulic testing of cooling spaces to 0.4MPa or 1.5 times the maximum working pressure, whichever is higher;
(7) overspeed test of all compressor wheels for a duration of 3 min at either 20% above alarm level speed at room temperature or 10% above alarm level speed at 45 ℃ inlet temperature when tested in the actual housing with the corresponding pressure ratio. The overspeed test may be waived for forged wheels that are individually controlled by an approved non-destructive method.
9.6.12.4 The certification requirements for turbochargers are to be in compliance with Chapter 3, PART ONE of the Rules.
9.6.12.5 The requirements of 9.6.12.1 to 9.6.12.4 also apply to replacement of rotating parts and casing.
9.6.12.6 Alternatively to the above periodic product audits, individual certification of a turbocharger and its parts may be made. However, such individual certification of category C turbocharger and its parts are to be based on test requirements specified in 9.6.12.3.

Section 7 FITTINGS

9.7.1 *Indicator valves*
9.7.1.1 An indicator valve is to be fitted to each cylinder cover of diesel engines having cylinder bore over 200 mm.

9.7.2 *Cylinder Safety valves*
9.7.2.1 A safety valve or equivalent means to prevent overpressure in the cylinders is to be fitted to each cylinder cover of diesel engines having cylinder bore over 230 mm. The safety valve is to be set at a pressure not more than 1.40 times the maximum combustion pressure and is to be so arranged that personal injury will not be caused by the outburst gas. For auxiliary engines, consideration will be given to the replacement of the relief valve by an efficient warning device of overpressure in the cylinder.

9.7.3 *Crankcases*
9.7.3.1 Crankcases and their doors are to be of robust construction and the doors are to be securely fastened so that they will not be readily displaced by an explosion.
9.7.3.2 The total volume of the stationary parts within the crankcase may be discounted in estimating the crankcase gross volume (rotating and reciprocating components are to be included in the gross volume).

9.7.4 *Crankcase relief valves*

9.7.4.1 In engines having cylinders not less than 200 mm bore or having a crankcase gross volume not less than 0.6 m^3, relief valves are to be installed according to the requirements of 9.7.4.2 to 9.7.4.6 of this Section.
9.7.4.2 In engines having cylinders exceeding 200 mm but not exceeding 250 mm bore, at least one relief valve is to be fitted near respectively each end of crankcase and an additional relief valve is to be fitted near the middle of the engine, where crank throws exceed eight.
9.7.4.3 In engine having cylinders exceeding 250 mm but not exceeding 300 mm bore, at least one relief valve is to be fitted in way of each alternate crank throw with a minimum of two valves. Relief valves are to be arranged from each end, where the cranks are of odd number.
9.7.4.4 In engines having cylinders exceeding 300 mm bore at least one relief valve is to be fitted in way of each main crank throw.
9.7.4.5 Additional relief valves are to be fitted for separate spaces on the crankcase, such as gear or chain cases for camshaft or similar drives, when the gross volume of such spaces exceeds 0.6 m^3.
9.7.4.6 The structural design of crankcase relief valves are to satisfy following requirements:
(1) The combined free area of the crankcase relief valves fitted on an engine is not to be less than 115 cm^2 per m^3 of the volume of the crankcase. The free area of each relief valve is not to be less than 45 cm^2.
(2) Crankcase explosion relief valves are to be provided with lightweight spring-loaded valve discs or other quick-acting and self-closing devices to relieve a crankcase of pressure in the event of an internal explosion and to prevent the inrush of air thereafter.
(3) The valve discs in crankcase explosion relief valves are to be made of ductile material capable of withstanding the shock of contact with stoppers at the full open position.
(4) Crankcase explosion relief valves are to be designed and constructed to open quickly and be fully open at a pressure not greater than 0.02 MPa.
(5) Crankcase explosion relief valves are to be provided with a flame arrester that permits flow for crankcase pressure relief and prevents passage of flame following a crankcase explosion.
(6) Where crankcase relief valves are provided with arrangements for shielding emissions from the valve following an explosion, the valve is to be type tested to demonstrate that the shielding does not adversely affect the operational effectiveness of the valves.
(7) Crankcase explosion relief valves are to be provided with a copy of manufacturer's installation and maintenance manual that is pertinent to the size and type of valve being supplied for installation on a particular engine. The manual is to contain the following information:
① description of valve with details of function and design limits;
② copy of type test certification;
③ installation instructions;
④ maintenance in service instructions to include testing and renewal of any sealing arrangements;
⑤ actions required after a crankcase explosion.
(8) A copy of the installation and maintenance manual required by 9.7.4.6(7) of this Section is to be provided on board ship.
(9) Valves are to be provided with suitable markings that include the following information:
① name and address of manufacturer;
② designation and size;
③ month/Year of manufacture;
④ approved installation orientation.
(10) Crankcase explosion relief valves are to be type tested in a configuration that represents the installation arrangements that will be used on an engine in accordance with Appendix 7 of this Chapter.

9.7.5 *Vent pipes*
9.7.5.1 Ventilation of crankcase, and any arrangement which could produce a flow of external air within the crankcase, are in principle not permitted except for gas fuel engines where crankcase ventilation is to be provided in accordance with the applicable requirements of Appendix 1 of this Chapter, ISC Rules for Ships Using Natural Gas Fuels and ISC Guidelines for Design and Installation of Gas Fuel Engine Systems of Liquefied Gas Carriers. Vent pipes, where provided, are to be as small as practicable to minimise the inrush of external air after a crankcase explosion.
9.7.5.2 In order to avoid the interconnection between crankcases and the possible spread of fire following an explosion, interconnection of ventilating pipes of two or more engines is not permitted nor that of oil drain pipes of crankcase.
9.7.5.3 If provision is made for the extraction of gases from within the crankcase, e.g. for smoke detection purpose, the vacuum within the crankcase is not to exceed 25 mm of water column.

9.7.6 Alarms①

9.7.6.1 Oil mist detection arrangements (or engine bearing temperature monitors or equivalent devices) are required for alarm and slowdown purposes for low speed diesel engines of 2,250 kW and above or having cylinders of more than 300 mm bore.

9.7.6.2 Oil mist detection arrangements (or engine bearing temperature monitors or equivalent devices) are required for alarm and automatic shutoff purposes for medium and high speed diesel engines of 2,250 kW and above or having cylinders of more than 300 mm bore.

9.7.6.3 Oil mist detection arrangements are to be of a type approved by classification societies and tested in accordance with Appendix 8 of this Chapter and comply with the requirements of 9.7.7 of this Section. Engine bearing temperature monitors or equivalent devices used as safety devices have to be of a type approved by classification societies for such purposes.

9.7.7 *Crankcase oil mist detection/monitoring system*

9.7.7.1 Crankcase oil mist detectors are to comply with the relevant requirements of PART SEVEN of the Rules in addition to 9.7.7.2 to 9.7.7.13 of this Section.

9.7.7.2 The oil mist detection/monitoring system and arrangements are to be installed in accordance with the engine designer's and oil mist manufacturer's instructions/recommendations. The following particulars are to be included in the instructions:

(1) Schematic layout of engine oil mist detection/monitoring and alarm system showing location of engine crankcase sample points and piping or electrical cable arrangements together with pipe dimensions to detector/monitor.

(2) Evidence of study to justify the selected location of sample points and sample extraction rate (if applicable) in consideration of the crankcase arrangements and geometry and the predicted crankcase atmosphere where oil mist can accumulate.

(3) The manufacturer's maintenance and test manual.

(4) Information relating to type or in-service testing of the engine with engine protection system test arrangements having approved types of oil mist monitoring equipment.

9.7.7.3 A copy of the oil mist detection/monitoring equipment maintenance and test manual required by 9.7.7.2 is to be provided on board ship.

9.7.7.4 Oil mist monitoring and alarm information is to be capable of being read from a safe location away from the engine.

9.7.7.5 Each engine is to be provided with its own independent oil mist detection arrangement and a dedicated alarm.

9.7.7.6 Oil mist detection/monitoring and alarm systems are to be capable of being tested on the test bed and board under engine at standstill and engine running at normal operating conditions in accordance with accepted test procedures.

9.7.7.7 The oil mist detection/monitoring arrangements are to provide an alarm indication in the event of a foreseeable functional failure in the equipment and installation arrangements.

9.7.7.8 The oil mist detection/monitoring system is to provide an indication that any lenses fitted in the equipment and used in determination of the oil mist level have been partially obscured to a degree that will affect the reliability of the information and alarm indication.

9.7.7.9 Where oil mist detection/monitoring equipment includes the use of programmable electronic systems, the arrangements are to be in accordance with relevant requirements of PART SEVEN of the Rules.

9.7.7.10 The equipment together with detectors/monitors is to be tested when installed on the test bed and on board ship to demonstrate that the detection/monitoring and alarm system functionally operates. The testing arrangements are to be submitted to ISC for approval.

9.7.7.11 Where sequential oil mist detection arrangements are provided for each crankcase, the sampling frequency and time is to be as short as reasonably practicable.

9.7.7.12 Where alternative methods are provided for the prevention of the build-up of oil mist that may lead to a potentially explosive condition within the crankcase, the following information is to be included in the details to be submitted for approval:

(1) Engine particulars – type, power, speed, stroke, bore and crankcase volume;

(2) Details of arrangements prevent the build-up of potentially explosive conditions within the crankcase, e.g. bearing temperature monitoring, oil splash temperature, crankcase pressure monitoring, recirculation arrangements;

(3) Evidence to demonstrate that the arrangements are effective in preventing the build-up of potentially explosive conditions together with details of in-service experience;

---

① For equivalent devices for high speed engines, refer to UI SC133.

(4) Operating instructions and the maintenance and test instructions.

9.7.7.13 Where it is proposed to use the introduction of inert gas into the crankcase to minimize a potential crankcase explosion, details of the arrangements are to be submitted for approval.

9.7.8 *Governors*

9.7.8.1 Main engines are to be provided with efficient governors to ensure that the speed of main engines does not exceed 115% of the rated speed.

9.7.8.2 When electronic speed governors of main engines form part of a remote control system, they are to comply with the following conditions:

(1) If lack of power to the governor may cause major and sudden changes in the present speed and direction of thrust of the propeller, back-up power supply is to be provided.

(2) Local control of the engines is always to be possible even in the case of failure in any part of the automatic or remote control systems, and to this purpose, from the local control position it is to be possible to disconnect the remote signal. A separate governor may be additionally fitted to satisfy the requirements for speed control specified in 9.7.8.1.

(3) Electronic speed governors and their actuators are to be type tested in accordance with ISC Guidelines for Type Approval Test of Electric and Electronic Products.

9.7.9 *Overspeed protective devices*

9.7.9.1 For each main engine developing 220 kW and above which drives a controllable pitch propeller or which can be declutched from the transmission shafting, an overspeed protective device is to be provided in addition to the governor prescribed in 9.7.8.1, so as to prevent the speed of main engines exceeding 120% of the rated speed. Equivalent arrangements may also be accepted subject to special consideration. Overspeed protective devices (including the driving mechanism) are to be independent of governors required by 9.7.8.1.

9.7.10 *Governors for generating sets*

9.7.10.1 Diesel engines intended for driving electric generators are to be provided with governors, which are to meet the following requirements:

They will prevent transient frequency variations in the electrical network in excess of ±10% of the rated frequency with a recovery time to steady state conditions not exceeding 5 s, when the maximum electrical step load is switched on or off. When the rated load is suddenly taken off, a transient speed variation in excess of 10% of the rated speed may be acceptable, provided this does not cause the intervention of the overspeed device as required by 9.7.10.3.

In various load conditions between no load and rated load, the permanent speed variation is not to exceed ±5% of the rated speed.

The selected prime mover is to satisfy the load demand within the ship's mains. Two step application of electrical load is to be achieved with the following method:

When 50% of the rated load is suddenly applied from no-load condition to the prime mover, followed by the remaining 50% load after an interval sufficient to restore the speed to steady state, the momentary variation in speed is not to exceed 10% of the rated speed, the recovery time for the engine speed (i.e. the time for speed fluctuation ratio to return to ±1%) is not to exceed 5 s.

Note: Steady state conditions are those at which the envelope of speed variation does not exceed ±1% of the declared speed at the new power.

For a prime mover for which only more than 2 load steps can be achieved, such load steps may be permitted provided that the use of such prime movers is permitted by the condition of ship's electrical network and such prime mover has been considered and approved for use at the design stage. Verification is to be carried out at ship's trials. When a four-stroke diesel engine with high supercharge is used as the prime mover for driving generator, application of electrical load in more than 2 load steps can be permitted in its governing characteristics tests (see Figure 9.7.10.1). Thus, the power necessary electrical installations being automatically switched on after block-out and the sequence in which it is connected are to be sufficiently considered in designing the load of ship's electric power station. This also applies analogously for generators to be operated in parallel and where the power has to be transferred from one generator to another in the event of any one generator has to be switched off.

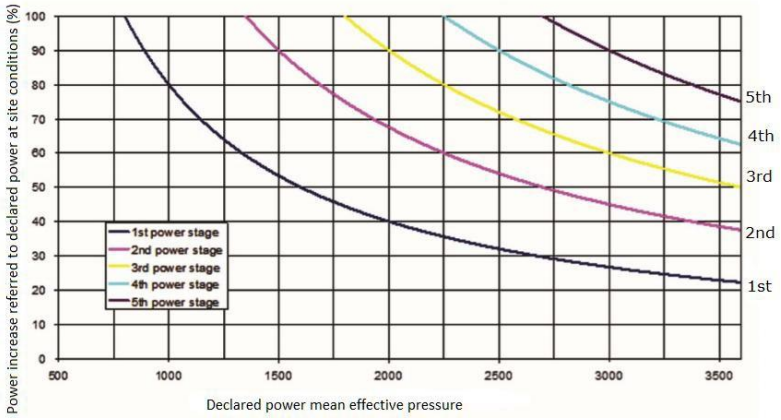


Figure 9.7.10.1①

9.7.10.2 Emergency generator sets must satisfy the governor conditions as per 9.7.10.1 even when their total consumer load is applied suddenly or in steps, subject to:
(1) the total load is supplied within 45 seconds since power failure on the main switchboard;
(2) the maximum step load is declared and demonstrated;
(3) the power distribution system is designed such that the declared maximum step loading is not exceeded;
(4) the compliance of time delays and loading sequence with the above is to be demonstrated at ship's trials.
9.7.10.3 For diesel engines driving electric generators and having a rated power of 220 kW and above, separate overspeed protective devices are to be provided in addition to the governors prescribed in 9.7.10.1, so as to prevent the speed of diesel engines exceeding 115% of the rated speed.
9.7.10.4 The construction and performance of governors for diesel engines intended for driving electric generators are to be in accordance with the relevant provisions specified in Chapter 3, PART FOUR of the Rules. If the generating sets are arranged to operate in parallel, their permanent speed variations are to be the same as far as possible.

9.7.11 *Instrumentation*

9.7.11.1 Tachometers and other necessary measuring instruments are to be fitted to diesel engines. Restricted speed ranges are to be marked red on tachometers.

9.7.12 *Warning notice*

9.7.12.1 A warning notice is to be fitted in a prominent position, preferably on a crankcase door on each side of the engine, or alternatively at the engine room control station. This warning notice is to specify that whenever overheating is suspected in the crankcase, the crankcase doors or sight holes are not to be opened until a reasonable time has elapsed after stopping the engine, sufficient to permit adequate cooling within the crankcase.

Section 8 INSTALLATION

9.8.1 *Bedplates*

9.8.1.1 Bedplates of main engines are to be reasonably rigid, and are to be securely fixed to the engine seatings of reasonable rigidity by means of holding-down bolts, or bolts and chocks, or bolts and thrust sleeves.
When holding-down bolts only are used, the number of fitting bolts is in general not to be less than 15% of the total number.
9.8.1.2 For installation of main engines, consideration is to be given to the effects of the engines on

① (1) The newly revised figure of multiple load steps of four-stroke diesel engines applies to speed governors for which an application for certification is dated on or after 1 January 2020 or which are installed in new ships contracted for construction on or after 1 January 2020.
(2) The "contracted for construction" date means the date on which the contract to build the vessel is signed between the prospective owner and shipbuilder
(3) The "date of application for certification" is the date of whatever document ISC requires/accepts as an application or request for certification of a speed governor.

crankshaft deflection in cold or hot condition. The crankshaft deflection of an installed engine is to be in accordance with the manufacturer's requirements for installation.

Section 9 ALARMS AND SAFEGUARDS FOR EMERGENCY DIESEL ENGINES

9.9.1 *General requirements*

9.9.1.1 Emergency diesel engines mainly include:
(1) a diesel engine generator used as the emergency source of electrical power;
(2) a diesel engine used to power the emergency fire pump;
(3) a diesel engine generator used as the independent source of power required for steering gear;
(4) other diesel engines used in an emergency.
9.9.1.2 This Section applies to diesel engines, which use distillate marine fuels covered by ISO 8217:2017, required to be immediately available in an emergency and capable of being controlled remotely or automatically operated.

9.9.2 *Alarms and safeguards*

9.9.2.1 The safety and alarm systems are to be designed to "fail safe" and satisfy the requirements of 2.1.3, PART SEVEN of the Rules.
9.9.2.2 Regardless of the engine output, shutdowns other than the overspeed shutdown specified in Table 9.9.2.5 are to be automatically overridden when the engine is in automatic or remote control mode during navigation.
9.9.2.3 The alarm system is to function in accordance with the relevant requirements of PART SEVEN of the Rules, with additional requirements that grouped alarms are to be arranged in the bridge.
9.9.2.4 In additional to the fuel oil control from outside the space, a local means of engine shutdown is to be provided.
9.9.2.5 Emergency diesel engines are to be fitted with alarms and safeguards in accordance with the requirements of Table 9.9.2.5. Local indications of at least those parameters listed in Table 9.9.2.5 are to be provided within the same space as the diesel engines and are to remain operational in the event of failure of the alarm and safety systems.

Alarms and Safeguards for Emergency Diesel Engines *Table 9.9.2.5*

Parameter	Alarm activation	Shutdown with alarm
Lubricating oil pressure	Low	
Lubricating oil temperature①	High	
Temperature of cooling water or cooling air	High	
Pressure or flow of cooling water①	Low	
Overspeed activated①	Overspeed	Shutdown
Fuel oil leakage from high pressure pipes (fuel injection pipes and common rails)	Oil leakage	
Activation of oil mist detection arrangements (or activation of the temperature monitoring systems or equivalent devices of: - the engine main and crank bearing oil outlet; or - the engine main and crank bearing)②	High	

Note: ① for engines having a power of or more than 220 kW.
② only for engines having a power of not less than 2,250 kW or a cylinder bore of more than 300 mm.

Section 10 SURVEY AND CERTIFICATION

9.10.1 **Approval and certification of diesel engines①**

① (1) The new requirements of type approval and type testing (including Appendix 4 and Appendix 5 of this Chapter) apply to engines for which the date of an application for type approval certification is dated on or after 1 July 2016.
(2) The "date of application for type approval" is the date of documents accepted by ISC as request for type approval certification of a new engine type or of an engine type that has undergone substantive modifications in respect of the

9.10.1.1 The type approval of diesel engines consists of drawing and specification approval, conformity of production, approval of type testing program, type testing of engines, review of the obtained type testing results, evaluation of the manufacturing arrangements and issue of a type approval certificate.
9.10.1.2 For each type of engine that is required to be approved, a Type Approval Certificate is to be obtained by the engine designer, and the maximum period of validity of a Type Approval Certificate is for 5 years. The process details for obtaining a Type Approval Certificate are given in Appendix 5 of this Chapter.
9.10.1.3 Each diesel engine intended for installation onboard a ship classed with ISC is to have a ISC marine product certificate. The certification process details for obtaining the engine certificate are in Appendix 5 "Approval and Certification of Diesel Engines" of this Chapter.

9.10.2 Type testing①

9.10.2.1 Type testing is required for every new engine type intended for installation onboard ships subject to classification in accordance with the requirements of Appendix 4 of this Chapter.
9.10.2.2 A type test carried out for a particular type of engine at any place of manufacture will be accepted for all engines of the same type built by licensees or the licensor, subject to each place of manufacture being found to be acceptable to ISC.
9.10.2.3 One type test will be considered adequate to cover a range of different numbers of cylinders. However, a type test of an in-line engine may not always cover the V-version. Subject to ISC' discretion, separate type tests may be required for the V-version. On the other hand, a type test of a V-engine covers the in-line engines, unless the bmep is higher.
Items such as axial crankshaft vibration, torsional vibration in camshaft drives, and crankshafts, etc. may vary considerably with the number of cylinders and may influence the choice of engine to be selected for type testing.
9.10.2.4 The engine is type approved up to the tested ratings and pressures (100% corresponding to MCR). Provided documentary evidence of successful service experience with the classified rating of 100% is submitted, an increase (if design appraisal is obtained ①②) may be permitted without a new type test if the increase from the type tested engine is within:
(1) 5% of the maximum combustion pressure, or
(2) 5% of the mean effective pressure, or
(3) 5% of the rpm.
Providing maximum power is not increased by more than 10%, an increase of maximum approved power may be permitted without a new type test provided engineering analysis and evidence of successful service experience in similar field applications (even if the application is not classified) or documentation of internal testing are submitted if the increase from the type tested engine is within:
(1) 10% of the maximum combustion pressure; or
(2) 10% of the mean effective pressure, or
(3) 10% of the rpm.

Notes:
①Where those engine data increase from the approved engine type, the crankshaft strength is to be reappraised, and the modified calculations and documents are to be submitted for approval.
② In this Chapter, design appraisal means evaluation of all drawings, information and calculations related to the design. See Glossary in Annex 1 of Appendix 5 of this Chapter.

9.10.2.5 If an engine has been subject to design appraisal, and internal testing per Stage A is documented to a rating higher than the one type tested, the Type Approval may be extended to the increased power/mep/rpm upon submission of an Extended Delivery Test Report at:
(1) test at over speed (only if nominal speed has increased);
(2) rated power, i.e. 100% output at 100% torque and 100% speed corresponding to load point 1, 2 measurements with one running hour in between;
(3) maximum permissible torque (normally 110%) at 100% speed corresponding to load point 3 or maximum permissible power (normally 110%) and speed according to nominal propeller curve corresponding to load point 3a., 0.5 h;
(4) 100% power at maximum permissible speed corresponding to load point 2, 0.5 h.
9.10.2.6 An integration test demonstrating that the response of the complete mechanical, hydraulic and

---

one previously type approved, or for renewal of an expired type approval certificate.
(3) Engines with an existing type approval on 1 July 2016 are not required to be re-type approved in accordance with the new requirements until the current type approval becomes invalid. The certification of such engines may be carried out in accordance with the current type approval and related submitted documentation.

electronic system is as predicted maybe carried out for acceptance of sub-systems (Turbo Charger, Engine Control System, Dual Fuel, Exhaust Gas treatment, etc.) separately approved. The scope of these tests is to be proposed by the designer/licensor taking into account of impact on engine.

9.10.3 *Works acceptance test and shipboard trials*

9.10.3.1 Factory acceptance test and shipboard trials of diesel engines are to be carried out in accordance with Appendix 6 of this Chapter.

9.10.3.2 The scope of test loads for various engine applications given in Appendix 6 may be expanded depending on the engine application, service experience, or other relevant reasons.

9.10.3.3 Alternatives to the detailed tests may be agreed between the manufacturer and ISC when the overall scope of tests is found to be equivalent to the provisions of Appendix 6.

Appendix 1 SAFETY OF LOW PRESSURE GAS FUEL ENGINES

1 *General Requirements*

1.1 Application and scope

1.1.1 This Appendix applies to trunk piston low pressure gas fuel engines supplied with natural gas as fuel. This Appendix only specifies relevant requirements for the use of gas fuel, and in addition, gas fuel engines are to comply with relevant provisions of this Chapter.

1.1.2 This Appendix is only supplementary to the rules. Gas fuel engines intended for gas carriers are to comply with relevant provisions of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk. Gas fuel engines intended for ships other than gas carriers are to comply with relevant provisions of ISC Rules for Ships Using Natural Gas Fuels.

1.1.3 Specific requirements of ISC Rules for Ships Using Natural Gas Fuels as referenced in this Appendix are to be applied to gas fuel engines installed on any ship, regardless of type, size and trading area, as long as ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk is not referenced or explicitly specified otherwise.

1.1.4 Gas fuel engines can be either dual fuel engines or gas fuel only engines. Gas fuel can be introduced as follows:

(1) into the air inlet manifold, scavenge space, or cylinder air inlet channel port; or

(2) mixed with air before the turbo-charger ("pre-mixed engines").

The gas / air mixture in the cylinder can be ignited by the combustion of a certain amount of fuel (pilot injection) or by extraneous ignition (sparking plug).

1.1.5 This Appendix covers the following applications, but is not limited to:

(1) mechanical propulsion;

(2) generating sets intended for main propulsion and auxiliary applications;

(3) single engine or multi-engine installations.

1.2 *Definitions*

(1) Certified safe type means electrical equipment that is certified in accordance with the recommendation published by the International Electrotechnical Commission (IEC), in particular publication IEC 60092-502, or with recognized standards at least equivalent. The certification of electrical equipment is to correspond to the category and group for methane gas.

(2) Double block and bleed valves means the set of valves referred to in 16.4.5 of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk and 1.1.2.10 and 6.2.1.5 of ISC Rules for Ships Using Natural Gas Fuels.

(3) Dual fuel engine ("DF engine") means an engine that can burn natural gas as fuel simultaneously with liquid fuel, either as pilot oil or bigger amount of liquid fuel (gas mode), and also has the capability of running on liquid diesel fuel oil only (Diesel mode).

(4) Engine room is a machinery space or enclosure containing gas fuelled engine(s).

(5) Gas means a fluid having a vapour pressure exceeding 0.28MPa absolute at a temperature of 37.8℃.

(6) Gas admission valve is a valve or injector on the engine, which controls gas supply to the cylinder(s) according to the cylinder(s) actual gas demand.

(7) Gas fuel engine means either a gas fuel only engine or a dual fuel engine.

(8) Gas fuel only engine ("GF engine") means an engine capable of operating on gas fuel only and not able to switch over to oil fuel operation.

(9) Gas piping means piping containing gas or air / gas mixtures, including venting pipes.

(10) Gas Valve Unit (GVU) is a set of manual shutoff valves, actuated shut-off and venting valves, gas pressure sensors and transmitters, gas temperature sensors and transmitters, gas pressure control valve and gas filter used to control the gas supply to each gas consumer. It also includes a connection for inert gas purging.

(11) IGC Code means the International Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk (as amended by IMO Resolutions MSC.370(93), MSC.411(97) and MSC.411(99)).

(12) IMO means the International Maritime Organisation.

(13) IGF Code means the International Code of Safety for Ships Using Gases or other Low-Flashpoint Fuels (IMO Resolution MSC.391(95), as amended by IMO Resolution MSC.422(98)).

(14) Low pressure gas means gas with a pressure up to 1.0 MPa.

(15) Lower Heating Value ("LHV") means the amount of heat produced from the complete combustion of a specific amount of fuel, excluding latent heat of vaporization of water.
(16) Methane Number is a measure of resistance of a gas fuel to knock, which is assigned to a test fuel based upon operation in knock testing unit at the same standard knock intensity.
Note: Pure methane is used as the knock resistant reference fuel, that is, methane number of pure methane is 100, and pure hydrogen is used as the knock sensitive reference fuel, methane number of pure hydrogen is 0.
(17) Pilot fuel means the fuel oil that is injected into the cylinder to ignite the main gas-air mixture on DF engines.
(18) Pre-mixed engine means an engine where gas is supplied in a mixture with air before the turbocharger.
(19) Recognized standards means applicable international or national standards acceptable to ISC or standards laid down and maintained by an organisation which complies with the standards adopted by IMO and which are recognized by the Classification Society.
(20) Safety Concept is a document describing the safety philosophy with regard to gas as fuel. It describes how risks associated with this type of fuel are controlled under reasonably foreseeable abnormal conditions as well as possible failure scenarios and their control measures.
Note: A detailed evaluation regarding the hazard potential of injury from a possible explosion is to be carried out and reflected in the safety concept of the engine.

1.3 *Plans and documents*

1.3.1 The following plans and documents are to be submitted for approval with regard to the approval of gas fuel engines, in addition to those required in 9.1.12.1, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships:

No.	Plans and documents
(1)	Schematic layout or other equivalent documents of gas system on the engine
(2)	Gas piping system (including double-walled arrangement where applicable)
(3)	Parts for gas admission system②
(4)	Arrangement of explosion relief valves (crankcase①, charge air manifold, exhaust gas manifold) as applicable
(5)	List of certified safe equipment and evidence of relevant certification
(6)	Schematic layout or other equivalent documents of fuel oil system (main and pilot fuel systems) on the engine (only for DF engine)
(7)	Shielding of high pressure fuel pipes for pilot fuel system, assembly (only for DF engine)
(8)	High pressure parts for pilot fuel oil injection system②(only for DF engine)
(9)	Ignition system (only for GF engine)
Note: ① If required by 9.1.12, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships. ② The documentation to contain specification of pressures, pipe dimensions and materials.	

1.3.2 The following plans and documents are to be submitted for information with regard to the approval of gas fuel engines, in addition to those required in 9.1.12.2, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships:

No.	Plans and documents
(1)	Safety concept
(2)	Report of the risk analysis①
(3)	Gas specification
(4)	Other plans and documents as deemed necessary by ISC
Note: ① see 1.4 of this Appendix.	

1.4 *Risk analysis*

1.4.1 The risk analysis is to address:
(1) a failure or malfunction of any system or component involved in the gas operation of the engine;
(2) a gas leakage downstream of the gas valve unit;
(3) the safety of the engine in case of emergency shutdown or blackout, when running on gas;
(4) the inter-actions between the gas fuel system and the engine.
Note: With regard to the scope of the risk analysis it shall be noted that failures in systems external to the engine, such as fuel storage or fuel gas supply systems, may require action from the engine control and monitoring system in the event of an alarm or fault condition. Conversely failures in these external systems may, from the vessel perspective, require additional safety actions from those required by the engine limited risk analysis.
1.4.2 The risk analysis is to be carried out in accordance with international standard ISO 31010: Risk

management - Risk assessment techniques, or other recognized standards.
The required analysis is to be based on the single failure concept, which means that only one failure needs to be considered at the same time. Both detectable and non-detectable failures are to be considered. Consequences failures, i.e. failures of any component directly caused by a single failure of another component, are also to be considered.
1.4.3 The risk analysis is to:
(1) Identify all the possible failures in the concerned equipment and systems which could lead:
① to the presence of gas in components or locations not designed for such purpose, and/or
② to ignition, fire or explosion.
(2) Evaluate the consequences.
(3) Where necessary, identify the failure detection method.
(4) Where the risk cannot be eliminated, identify the corrective measures, e.g. in the system design such as redundancies or safety devices, monitoring or alarm provisions which permit restricted operation of the system; in the system operation, such as initiation of the redundancy or activation of an alternative mode of operation.
The results of the risk analysis are to be documented.
1.4.4 The risk analysis required for engines is to cover at least the following equipment and systems
(1) failure of the gas-related systems or components, in particular gas piping and its enclosure, where provided and cylinder gas supply valves. Failures of the gas supply components not located directly on the engine, such as block-and-bleed valves and other components of the Gas Valve Unit (GVU), are not to be considered in the analysis;
(2) failure of the ignition system (oil fuel pilot injection for DF engines or sparking plugs for GF engines);
(3) failure of the air to fuel ratio control system (charge air by-pass, gas pressure control valve, etc.);
(4) for engines where gas is injected upstream of the turbocharger compressor, failure of a component likely to result in a source of ignition (hot spots);
(5) failure of the gas combustion or abnormal combustion (misfiring, knocking);
(6) failure of the engine monitoring, control and safety systems;
Note: Where engines incorporate electronic control systems, a failure mode and effects analysis (FMEA) is to be carried out in accordance with 9.1.12.2(23) and Note 5, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships.
(7) abnormal presence of gas in engine components (e.g. air inlet manifold and exhaust manifold of DF or GF engines) and in the external systems connected to the engines (e.g. exhaust duct);
(8) changes of operating modes for DF engines, including fuel oil mode, gas fuel mode and other working mode;
(9) hazard potential for crankcase fuel gas accumulation, for engines where the space below the piston is in direct communication with the crankcase, refer to 7.2.1.6 of ISC Rules for Ships Using Natural Gas Fuels.

2 *Design Requirements*

2.1 General principles
2.1.1 The manufacturer is to declare the allowable gas composition limits for the engine and the minimum and (if applicable) maximum methane number.
2.1.2 Components containing or likely to contain gas are to be designed to:
(1) minimise the risk of fire and explosion so as to demonstrate an appropriate level of safety commensurate with that of an oil-fuelled engine;
(2) mitigate the consequences of a possible explosion to a level providing a tolerable degree of residual risk, due to the strength of the component(s) to withstand the overpressure due to the ignition of leaked gas in the most severe condition or the fitting of suitable pressure relief devices of an approved type.
Also refer to 7.1.2 and Section 2 of ISC Rules for Ships Using Natural Gas Fuels.
Note:
① Discharge from pressure relief devices is to prevent the passage of flame to the machinery space and be arranged such that the discharge does not endanger personnel or damage other engine components or systems.
② Relief devices are to be fitted with a flame arrester.

2.2 *Design requirements*
2.2.1 For gas carriers, engine-mounted gas piping is to be designed and manufactured in accordance with 5.1 to 5.9 of Chapter 5 and Chapter 16 of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk. For ships other than gas carriers, the piping is to be designed in accordance with the criteria for gas piping (design pressure, wall thickness, materials, piping fabrication and joining details

etc.) as given in Chapter 3 of ISC Rules for Ships Using Natural Gas Fuels.

2.2.2 Arrangement of the gas piping system on the engine

(1) Pipes and equipment containing fuel gas are defined as hazardous area Zone 0 (refer to 9.2.2.1 of ISC Rules for Ships Using Natural Gas Fuels).

(2) The space between the gas fuel piping and the wall of the outer pipe or duct is defined as hazardous area Zone 1 (refer to 9.2.2.2(6) of ISC Rules for Ships Using Natural Gas Fuels).

(3) For gas carriers, the gas fuel piping system on the engine is to be arranged in accordance with 16.4.3 of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk. For ships other than gas carriers, the piping is to be arranged in accordance with the principles and requirements of 6.4.1.1 and 6.4.1.2 of ISC Rules for Ships Using Natural Gas Fuels.

The double pipe or duct is to be designed in accordance with 3.3.1.4, 6.4.1.3 and 6.4.1.4 of ISC Rules for Ships Using Natural Gas Fuels.

In case of a ventilated double wall, for gas carriers, the ventilation inlet is to be arranged in accordance with 16.4.3.2 of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk. For ships other than gas carriers, the ventilation inlet is to be arranged in accordance with 10.6.1.3 of ISC Rules for Ships Using Natural Gas Fuels.

The pipe or duct is to be pressure tested in accordance with 2.7.1, Chapter 2, PART THREE of ISC Rules for Classification of Sea-going Steel Ships to ensure gas tight integrity and to show that it can withstand the expected maximum pressure at gas pipe rupture.

(4) Single walled gas piping is only acceptable:

① for engines installed in ESD protected machinery spaces, as defined in 2.3.1.1(2) of ISC Rules for Ships Using Natural Gas Fuels and in compliance with other relevant requirements of ISC Rules for Ships Using Natural Gas Fuels (e.g. 2.3.3);

② in the case as per 6.4.1.2(1) of ISC Rules for Ships Using Natural Gas Fuels.

For gas carriers, the requirements of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk apply.

In case of gas leakage in an ESD-protected machinery space, which would result in the shutdown of the engine(s) in that space, a sufficient propulsion and manoeuvring capability including essential and safety systems is to be maintained. Therefore the safety concept of the engine is to clearly indicate application of the "double wall" or "alternative" arrangement.

Note: The minimum power to be maintained is to be assessed on a case-by-case basis from the operational characteristics of the ship.

2.2.3 Charge air system on the engine

(1) The charge air system on the engine is to be designed in accordance with 2.1.2 above.

(2) In case of a single engine installation, the engine is to be capable of operating at sufficient load to maintain power to essential consumers after opening of the pressure relief devices caused by an explosion event. Sufficient power for propulsion capability is to be maintained.

Note: Load reduction is to be considered on a case by case basis, depending on engine configuration (single or multiple) and relief mechanism (self-closing valve or bursting disk).

2.2.4 Exhaust system on the engine

(1) The exhaust gas system on the engine is to be designed in accordance with 2.1.2 above.

(2) In case of a single engine installation, the engine is to be capable of operating at sufficient load to maintain power to essential consumers after opening of the pressure relief devices caused by an explosion event. Sufficient power for propulsion capability is to be maintained. Continuous relief of exhaust gas (through open rupture disc) into the engine room or other enclosed spaces is not acceptable.

2.2.5 Protection of crankcase

(1) Crankcase explosion relief valves are to be installed in accordance with 9.7.4, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships. Refer also to 7.2.1.6 of ISC Rules for Ships Using Natural Gas Fuels.

(2) For maintenance purposes, a connection, or other means, are to be provided for crankcase inerting and ventilating and gas concentration measuring.

2.2.6 With regard to gas ignition in the cylinder, for gas carriers, the requirements of 16.7 of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk apply; for ships other than gas carriers, the requirements of Section 2 of Chapter 7 of ISC Rules for Ships Using Natural Gas Fuels apply.

2.2.7 Control, monitoring, alarm and safety systems

(1) The engine control system is to be independent and separate from the safety system.

(2) The gas supply valves are to be controlled by the engine control system or by the engine gas demand.

(3) Combustion is to be monitored on an individual cylinder basis.

(4) In the event that poor combustion is detected on an individual cylinder, gas operation may be allowed in

the conditions specified in 7.2.1.13 of ISC Rules for Ships Using Natural Gas Fuels.
(5) If monitoring of combustion for each individual cylinder is not practicable due to engine size and design, common combustion monitoring may be accepted.
(6) Unless the risk analysis required by 1.4 of this Appendix proves otherwise, the monitoring and safety system functions for DF or GF engines are to be provided in accordance with Table 1 of this Appendix in addition to the general monitoring and safety system functions given by ISC Rules for Classification of Sea-going Steel Ships.
Note: For DF engines, Table 1 applies only to the gas mode.

Monitoring and Safety System Functions for Gas Fuel Engines Table 1

Parameter	Alarm	Automatic activation of the double block-and bleed valves	Automatic switching over to oil fuel mode①	Engine shutdown
Abnormal pressures in the gas fuel supply line	×	×	×	× ⑤
Gas fuel supply systems - malfunction	×	×	×	× ⑤
Pilot fuel injection or spark ignition systems - malfunction	×	× ②	×	× ②⑤
Exhaust gas temperature after each cylinder - high	×	× ②	×	×②⑤
Exhaust gas temperature after each cylinder, deviation from average – low③	×	× ②	×	× ②⑤
Cylinder pressure or ignition - failure, including misfiring, knocking and unstable combustion	×	× ②④	× ④	× ②④⑤
Oil mist concentration in crankcase or bearing temperature⑥ - high	×	×		×
Pressure in the crankcase – high④	×	×	×	
Engine stops - any cause	×	×		
Failure of the control-actuating medium of the block and bleed valves	×	×	×	

Symbol: × Applicable
Note:
① DF engine only, when running in gas mode.
② For GF engines, the double block-and-bleed valves and the engine shutdown may not be activated in case of specific failures affecting only one cylinder, provided that the concerned cylinder can be individually shutoff and the safe operation of the engine in such conditions is demonstrated by the risk analysis.
③ Required only if necessary for the detection of misfiring.
④ In the case where the failure can be corrected by an automatic mitigation action, only the alarm may be activated. If the failure persists after a given time, the safety actions are to be activated.
⑤ GF engine only.
⑥ Where required by 9.7.6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships.

2.2.8 Gas admission valves are to be certified safe as follows:
(1) The inside of the valve contains gas and is therefore to be certified for Zone 0.
(2) When the valve is located within a pipe or duct in accordance with 2.2.2(2), the outside of the valve is to be certified for Zone 1.
(3) When the valve is arranged without enclosure in accordance with the "ESD-protected machinery space" (see 2.2.2(4)) concept, no certification is required for the outside of the valve, provided that the valve is de-energized upon gas detection in the space.
However, if they are not rated for the zone they are intended for, it is to be documented that they are suitable for that zone. Documentation and analysis is to be based on IEC 60079-10-1 or IEC 60092-502.

3 *Specific Design Requirements*

3.1 DF Engines

3.1.1 The maximum continuous power that a DF engine can develop in gas mode may be lower than the approved MCR of the engine (i.e. in oil fuel mode), depending in particular on the gas quality. This maximum power available in gas mode and the corresponding conditions are to be stated by the engine manufacturer and demonstrated during the type test. The 110% load tests are not required in the gas mode

of DF engines when 4.1.4, 4.2.1 and 4.3 of this Appendix are implemented in accordance with the provisions in 1.3 of Appendix 4, 2.3 and 3.4 of Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships.

3.1.2 DF engines are to be arranged to use either oil fuel or gas fuel for the main fuel charge and with pilot oil fuel for ignition. The engines are to be arranged for rapid changeover from gas use to fuel oil use. In the case of changeover to either fuel supply, the engines are to be capable of continuous operation using the alternative fuel supply without interruption to the power supply.

Changeover to gas fuel operation is to be only possible at a power level and under conditions where it can be done with acceptable reliability and safety as demonstrated through testing.

Changeover from gas fuel operation mode to oil fuel operation mode is to be possible at all situations and power levels.

The changeover process itself from and to gas operation is to be automatic but manual interruption is to be possible in all cases.

In case of shut-off of the gas supply, the engines are to be capable of continuous operation by oil fuel only.

3.1.3 Gas supply to the combustion chamber is not to be possible without operation of the pilot oil injection.

Note: Pilot injection is to be monitored for example by fuel oil pressure and combustion parameters.

3.2 *GF Engines*

3.2.1 In case of failure of the spark ignition, the engine is to be shut down except if this failure is limited to one cylinder, subject to immediate shut off of the cylinder gas supply and provided that the safe operation of the engine is substantiated by the risk analysis and by tests.

3.3 *Pre-Mixed Engines*

3.3.1 Inlet manifold, turbo-charger, charge air cooler, etc. are to be regarded as parts of the fuel gas supply system. Failures of those components likely to result in a gas leakage are to be considered in the risk analysis (see 1.4 of this Appendix).

3.3.2 Flame arresters are to be installed before each cylinder head, unless otherwise justified in the risk analysis, considering design parameters of the engine such as the gas concentration in the charge air system, the path length of the gas-air mixture in the charge air system, etc.

4 *Type Testing, Factory Acceptance Tests and Shipboard Trials*

4.1 Type Testing

4.1.1 Type approval of DF and GF engines is to be carried out in accordance with 9.10.1 and 9.10.2, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, taking into account the additional requirements below.

4.1.2 In addition to the criteria given in 9.1.2.1(1), Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, the type of engine is defined by the following:

(1) gas admission method (direct cylinder injection, charge air space or pre-mixed);

(2) gas supply valve operation (mechanical or electronically controlled);

(3) ignition system (pilot injection, spark ignition, glow plug or gas self-ignition);

(4) ignition system (mechanical or electronically controlled).

4.1.3 In addition to the safety precautions mentioned in 1.2, Appendix 4, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, measures to verify that gas fuel piping on engine is gas tight are to be carried out prior to start-up of the engine.

4.1.4 The type testing of the engine is to be carried out in accordance with 1.3, Appendix 4, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships.

For DF engines, the load tests are to be carried out in gas mode at the different percentages of the maximum power available in gas mode (see 3.1.1 of this Appendix).

The influence of the methane number and LHV of the fuel gas is not required to be verified during the Stage B type tests. It is however to be justified by the engine designer through internal tests or calculations and documented in the type approval test report.

4.1.5 In addition to the measurements and records required in 1.4, Appendix 4, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, the following engine data are to be measured and recorded:

(1) Each fuel index for gas and diesel as applicable (or equivalent reading).

(2) Gas pressure and temperature at the inlet of the gas manifold.

(3) Gas concentration in the crankcase.

Additional measurements may be required in connection with the design assessment.

4.1.6 In addition to internal tests required in 2.1, Appendix 4, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, the following conditions are to be tested:

(1) DF engines are to run the load points in both gas and diesel modes (with and without pilot injection in service) as found applicable for the engine type.

(2) For DF engines with variable liquid / gas ratio, the load tests are to be carried out at different ratios between the minimum and the maximum allowable values.

(3) For DF engines, switch over between gas and diesel modes are to be tested at different loads.

4.1.7 Witnessed tests are to be carried out in accordance with 2.2, Appendix 4, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships. The following requirements are to be considered:

(1) The following test conditions are to be considered for DF engine during the load test:

① All load points must be run in both gas and diesel modes that apply for the engine type as defined by the engine designer. This also applies to the overspeed test.

② In case of DF engines with variable liquid / gas ratio, the load tests are to be carried out at different ratios between the minimum and the maximum allowable values.

(2) The following items are to be carried out for functional test:

① For DF engines, the lowest specified speed is to be verified in diesel mode and gas mode.

② For DF engines, switch over between gas and diesel modes are to be tested at different loads.

③ The efficiency of the ventilation arrangement of the double walled gas piping system is to be verified.

④ Simulation of a gas leakage in way of a cylinder gas supply valve.

Engines intended to produce electrical power are to be tested as follows:

① Capability to take sudden load and loss of load in accordance with the provisions of 9.7.10.1, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships.

② For GF and premixed engines, the influences of LHV, methane number and ambient conditions on the dynamic load response test results are to be theoretically determined and specified in the test report. Referring to the limitations as specified in 2.1.1 of this Appendix, the margin for satisfying dynamic load response is to be determined.

Notes:

1. For DF engines, switchover to oil fuel during the test is acceptable.
2. Application of electrical load in more than 2 load steps can be permitted in the conditions stated in 9.7.10.1, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships.

(3) GF and DF engines are to undergo integration tests to verify that the response of the complete mechanical, hydraulic and electronic engine system is as predicted for all intended operational modes. The scope of these tests is to be agreed with ISC for selected cases based on the risk analysis, and is at least to include the following incidents:

① Failure of ignition (spark ignition or pilot injection systems), both for one cylinder unit and common system failure;

② Failure of a cylinder gas supply valve;

③ Failure of the combustion (to be detected by e.g. misfiring, knocking, exhaust temperature deviation, etc.);

④ Abnormal gas pressure;

⑤ Abnormal gas temperature*.

Note*: This test may be carried out using a simulation signal of the temperature.

4.1.8 Component inspection is to be carried out in accordance with the provisions of 2.3, Appendix 4, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships. The components to be inspected after the test run are to include also:

(1) gas supply valve including pre-chamber as found applicable;

(2) spark igniter (for GF engines);

(3) pilot fuel injection valve (for DF engines).

4.2 *Factory acceptance test*

4.2.1 Factory acceptance tests are to be carried out in accordance with Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, taking into account the additional requirements below.

For DF engines, the load tests referred to in 2.3, Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships are to be carried out in gas mode at the different percentages of the maximum power available in gas mode (see 3.1.1 of this Appendix).

4.2.2 In addition to the safety precautions mentioned in 1.1, Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, measures to verify that gas fuel piping on engine is gas tight are to be carried out prior to start-up of the engine.

4.2.3 In addition to the records required in 2.2, Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships, the following engine data are to be recorded:

(1) Fuel index, both gas and diesel as applicable (or equivalent reading);

(2) Gas pressure and temperature.

4.2.4 Test loads for various engine applications are given in 2.3, Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships. DF engines are to be tested in both diesel and gas mode as found applicable. In addition the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

4.2.5 Gas fuel engines are to undergo integration tests to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes.

The scope of these tests is to be agreed with ISC for selected cases based on the risk analysis and is at least to include the following incidents:

① Failure of ignition (spark ignition or pilot injection systems), for one cylinder unit;

② Failure of a cylinder gas supply valve;

③ Failure of the combustion (to be detected by e.g. misfiring, knocking, exhaust temperature deviation, etc.);

④ Abnormal gas pressure;

⑤ Abnormal gas temperature.

Note: The above tests may be carried out using simulation or other alternative methods, subject to special consideration by ISC.

4.3 *Shipboard trials*

4.3.1 Shipboard trials are to be carried out in accordance with the provisions of Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships. For DF engines, the test loads are to be carried out in all operating modes (gas mode, diesel mode, etc.). For DF engines, when load tests specified in 3.4, Appendix 6, Chapter 9, PART THREE of ISC Rules for Classification of Sea-going Steel Ships are carried out in gas mode, test loads are taken as each percentage of the maximum output power in gas mode (see 3.1.1 of this Appendix).

Appendix 2 GUIDELINES FOR ELECTRONICALLY CONTROLLED DIESEL ENGINES

1. General Provisions

1.1 Application

1.1.1 The Guidelines apply to electronically controlled diesel engines.

1.1.2 In addition to the requirements of the Guidelines, electronically controlled diesel engines are to comply with other requirements of this Chapter.

1.1.3 With the advancement of the electronic control technology of diesel engines and the development of intelligent diesel engines, the Guidelines will not limit the progress and development of this new technology.

1.1.4 Where a single electronic control system is used in diesel engines, the applicable requirements of the Guidelines may be referred to.

1.2 *General requirements*

1.2.1 The safety required and functions of electronically controlled diesel engines are not to be inferior to those of non-electronically controlled diesel engines.

1.2.2 The electronic control system is to operate safely and reliably under operating conditions of diesel engines.

1.2.3 The guaranteed working period and the maintenance of the electronic control system are in general to be indicated in product instructions.

1.3 *Definitions*

1.3.1 For the purpose of the Guidelines:

(1) **Electronically controlled diesel engine** means a diesel engine with an electronic control system where system parameters can be adjusted flexibly by control equipment such as ECU to further improve the flexibility and adaptability of individual systems to match the diesel engine, and to optimize its operation and performance.

(2) **Non-electronically controlled diesel engine** means a diesel engine without an electronic control system.

(3) **Intelligent diesel engine** generally means a diesel engine where a comprehensive electronic control is applied to individual systems of fuel oil injection, air intake and exhaust, oil or water cooling, cylinder lubricating, exhaust turbocharging and vibration balance so as to fully optimize system parameters, lower consumption, decrease environmental pollution (low harmful discharge, low noise, low vibration), and automatically monitor its operation and failures.

(4) **Electronic control system of diesel engine:** According to different objects, methods and parameters, an electronic control system of diesel engines has various options and forms, of which the most important is the electronically controlled fuel oil system. It controls parameters such as fuel injection pressure, time, amount and mode. The electronic control system which can flexibly adjust parameters of each system of a diesel engine is called electronic control system of diesel engine, composed of sensors, electronic control units (ECU) and actuators.

(5) **Sensor** means a device or an apparatus which detects ambient conditions, working conditions and various operating parameters of the diesel engine. There are mainly crankshaft speed sensor, pressure sensor, temperature sensor, humidity sensor, gas composition sensor, TDC position sensor, massflow sensor and vibration sensor, which are selected according to electronic control systems of various diesel engines.

(6) **Electronic control unit (ECU)** deals with input information, outputs the results and drives actuators. ECU is mainly composed of a microcomputer, an interface circuit, a drive circuit and necessary software.

(7) **Actuator means a mechanism which** receives control orders from ECU and initiates actions to operate relevant components of the diesel engine. An actuator is mainly composed of an electromagnetic valve, a step motor, electrohydraulic equipment and pipes. The driving power of actuators includes electric power and hydraulic power. Electric drive is operated by the step motor and generally used in cases with less driving power and less strict real-time requirements, such as electronic speed governor, control of variable nozzles of small turbochargers, control of adjustable valves of cooling and lubricating systems. Hydraulic drive is operated by hydraulic power controlled by the electromagnetic valve, such as used in injection systems and air intake and exhaust systems where power transmission is without camshaft.

(8) **Common rail (pressure accumulator)** means a pressure vessel used to supply high pressure fuel oil or

hydraulic oil within the fuel oil or hydraulic oil system of an electronically controlled diesel engine.

2. Design and Installation

2.1 ***Fuel oil and hydraulic oil systems***

2.1.1 Fuel oil and hydraulic oil systems are to comply with the applicable requirements of Chapters 2, 4 and 9 of this PART.

2.1.2 The strength of fuel oil and hydraulic oil pressure accumulators is to comply with the relevant requirements of Chapter 6 of this PART.

2.1.3 For electronically controlled diesel engines intended for single main engine propulsion systems, at least two fuel oil and two hydraulic oil pressure pumps are to be provided for their respective service. The capacity of all pumps are to ensure maximum continuous rating of main propulsion diesel engine, and in case of failure of any one fuel oil and/or hydraulic oil pressure pump, the capacity of other pumps are to ensure that the main propulsion diesel engine can output power necessary for normal navigation. All pumps are to be arranged ready for immediate use. For electronically controlled diesel engines intended for multiple main engines propulsion systems, each diesel engine is at least to be provided with one fuel oil pressure pump and one hydraulic oil pressure pump to ensure maximum continuous rating of diesel engines. One common standby pump connected ready for immediate use is needed, or alternatively, a complete spare pump may be accepted, provided that it is readily accessible and can easily be installed.

2.1.4 The fuel oil pressure piping between the high pressure fuel oil pumps and the fuel oil injectors is to be protected with a jacketed piping system or other equivalent means capable of preventing fuel oil leakage from splashing onto sources of ignition.

2.1.5 The piping between the high pressure hydraulic oil pumps and the hydraulic actuators is to be protected with a jacketed piping system capable of preventing hydraulic oil leakage from splashing onto sources of ignition.

2.1.6 Isolating valves and cocks are to be located as near as practicable to the equipment to be isolated. All valves forming part of the fuel oil and hydraulic oil installations are to be capable of being controlled from readily accessible positions above the working platform.

2.1.7 High pressure fuel oil and high pressure hydraulic oil piping systems are to be provided with high pressure alarms with set points that do not exceed the system design pressures.

2.1.8 High pressure fuel oil and high pressure hydraulic oil piping systems are to be provided with suitable relief valves on any part of the system that can be isolated and in which pressure can be generated. The settings of the relief valves are not to exceed the design pressures. The valves are to be of adequate size and so arranged as to avoid an undue rise in pressure above the design pressures.

2.1.9 Equipment fitted for monitoring pressures and temperatures in the high pressure fuel oil and high pressure hydraulic oil systems is to comply with the requirements of ISC Guidelines for Type Approval Test of Electric and Electronic Products in respect to the anticipated vibration and temperature conditions.

2.1.10 In general, dual high pressure fuel oil and high pressure hydraulic oil piping systems are to be provided. Where a fatigue analysis has been carried out (all anticipated pressure, pulsation and vibration loads are to be addressed), single systems may be accepted.

2.1.11 Means are to be provided to prevent continuous injection of fuel oil into cylinders due to failure of control valves.

2.2 Electronic control systems

2.2.1 The design, manufacture and inspection of the electronic equipment used for electronic control systems, including software design, are to comply with the relevant requirements in PART SEVEN of the Rules and ISC Guidelines for Type Approval Test of Electric and Electronic Products.

2.2.2 Electronic control systems are to have the functions of failure self-diagnosis and fail-safe protection. In case of failure, the system is to immediately perform a self-diagnose and initiate appropriate fail-safe protection to maintain operation of the diesel engine.

2.2.3 Those devices in the electronic control system which will affect normal operation of the main propulsion engine in case of functional failure, such as ECUs and crankshaft rotation angle indicators, are to be provided as dual systems. The type and function of such dual systems are to be fully identical. When one system fails, the other will automatically take over so as to maintain normal operation of the engine and an alarm will be given at the same time. For electronically controlled diesel engines intended for ships with two or more main propulsion diesel engines, if risk analysis indicates that in case of failure of electronic control system of any one diesel engine, the others remain capable of outputting power necessary for normal navigation, dual electronic control systems are not necessary for each diesel engine. The electronic control system out of order is to be readily replaced and put into service.

2.2.4 The power for the electronic control system is to be supplied by two independent feeders from two independent power sources.
2.2.5 Local controls and a central control room or bridge control system are to be provided.
2.2.6 The monitoring performed by the electronic control system is to be able to initiate alarms when main functions of sensors, ECUs and actuators fail.
2.2.7 The electronic control system is to be able to monitor the working condition of diesel engines, automatically adjust individual system parameters, and automatically detect and given alarms for failures of systems and components.
2.2.8 Components and parts of the electronic control system are to be changeable considering functional characteristics and structural dimensions, and capable of being disassembled, replaced and installed quickly.
2.2.9 For corrosive materials, anticorrosive coating is to be provided. Where parts made of different metals contact directly each other, means are generally to be provided to prevent electrolytic corrosion.
2.2.10 Electronic control systems are to be provided with test ports to facilitate test and maintenance.

2.3 Failure Mode and Effects Analysis (FMEA)

2.3.1 A Failure Mode and Effects Analysis (FMEA) is to demonstrate that a failure of the functioning of any device or circuit of fuel oil, lubricating oil, hydraulic, starting air, cooling water, and control and safety systems of the electronically controlled diesel engine will not result in the failure or deterioration of the function of other devices or circuits.
2.3.2 An FMEA analysis report is in general to address the following issues:
(1) the standards used for analysis and system design;
(2) the objectives of the analysis;
(3) any assumptions made in the analysis;
(4) the equipment, system or sub-system, mode of operation;
(5) potential failure modes and their causes;
(6) evaluation of the effects of each failure mode;
(7) measures for reducing the risks associated with each failure mode.
2.3.3 Failures of components of the equipment itself need not be taken into account for the analysis.

2.4 Installation

2.4.1 The installation of components of an electronic control system is to comply with the requirements for installation positions on the diesel engine, interface dimension, joints, screening, heat and shock resistance. The components are to be capable of being easily installed and fixed on the diesel engine. The wiring of all electronic circuits is to be secure and reliable to prevent loosening during operation.
2.4.2 When installing components with vibration dampers, sufficient spacing is to be left around to avoid collision with adjacent components or structures.

3 Tests

3.1 General requirements

3.1.1 Electronically controlled diesel engines are to be subjected to type tests, trials at the manufacturer's works and shipboard trials in accordance with the relevant requirements of this Chapter.
3.1.2 For test items related to electronic control systems, refer to the applicable requirements of the Guidelines.

3.2 Type tests

3.2.1 Main components of the electronic control system are to be type tested.
3.2.2 The type test of the electronic control system may also be carried out with the type test of the diesel engine at the same time.
3.2.3 The purpose of the type test of an electronically controlled diesel engine is to confirm normal function of the electronic control system after switch-in. Prior to test, piping, electrical circuits, sensors and actuators of the electronic control system are to be functionally verified and the installation of the system software into each module according to respective downloading instructions is to be confirmed.
3.2.4 Test scope:
(1) functions in respect to safe operation of the diesel engine;
(2) functions which can only be tested together with the diesel engine;
(3) verification of functions of the system software.
3.2.5 The effective functions of an electronic control system are to be verified during tests, generally

including the following items (if applicable):
(1) one crankshaft rotation angle indicator failing;
(2) one control module failing;
(3) one power supply unit failing;
(4) failure of fuel oil injection control valve of one cylinder;
(5) one communication network failing;
(6) main operation panel failing;
(7) earth failure;
(8) failure of action control station;
(9) one stop signal failing;
(10) other applicable failure and function tests.

3.3 Works trials

3.3.1 Prior to test, piping, electrical circuits, sensors and actuators of the electronic control system are to be functionally verified.

3.3.2 During testing of electronically controlled diesel engines, control parameters are to be checked.

3.3.3 The effective functions of an electronic control system are to be verified during tests, generally including the following items (if applicable):
(1) confirmation of software version;
(2) function of fuel oil injection control valve;
(3) function of exhaust control valve;
(4) power supply failure of control module of one cylinder;
(5) function of arrangements for emergency stopping;
(6) one crankshaft rotation angle sensor failing;
(7) other applicable failure and function tests.

3.4 Shipboard trials

3.4.1 Prior to trial, the examination of the items of control and remote control systems of diesel engines in respect to electronic control is to be confirmed.

Appendix 3 APPRAISAL OF CRANKSHAFT STRENGTH OF DIESEL ENGINES

1 General Provisions

1.1 Scope

1.1.1 The calculation methods in this Appendix are to be applied to diesel engines for propulsion and auxiliary purposes, where the engines are capable of continuous operation at their rated power when running at rated speed.

1.1.2 Where the calculation methods in this Appendix cannot be directly used for check in design, detailed design calculations or measurements are to be submitted for approval.

1.1.3 Where a crankshaft design involves the use of surface treated fillets, or when fatigue parameter influences are tested, or when working stresses are measured, the relevant documents with calculations/analysis are to be submitted in order to demonstrate equivalence to the calculation methods in this Appendix.

1.2 Requirements for calculation

1.2.1 This Appendix provides two calculation methods, i.e. the Calibration of Crankshaft Fatigue Strength (IACS) in Section 2 and the Calibration of Crankshaft Diameter in Section 3.

1.2.2 Steel crankshafts are to be subjected to the calibration of their fatigue strength in accordance with Section 2 of this Appendix.

1.2.3 Crankshafts, which are made of nodular graphite cast iron or to which Section 2 of this Appendix is not applicable, may be subjected to the calibration of their diameters in accordance with Section 3 of this Appendix.

1.3 Drawings and particulars

1.3.1 Drawings and particulars to be submitted

(1) When the calculation method for crankshaft fatigue strength check (IACS) is adopted, drawings and particulars are to be submitted according to the requirements of Table 1.3.1.

Data Sheet for Calculation of Crankshafts for Diesel Engines Table 1.3.1

1	Engine builder		
2	Engine type designation		
3	Stroke – Cycle ☐2 SCSA ☐4 SCSA		
4	Kind of engine ☐In-line engine ☐V-type engine with adjacent connecting-rods ☐V-type engine with articulated-type connecting-rod ☐V-type engine with forked/inner connecting rod ☐Crosshead engine ☐Trunk piston engine		
5	Combustion method ☐Direct injection ☐Precombustion chamber ☐Others		
6	For designation of cylinders, see Figure 1.3.1(1) of this Appendix		
7	Sense of rotation ☐Clockwise ☐Counterclockwise		
8	Firing order		
9	Firing intervals [deg]		
10	Rated power		kW
11	Rated engine speed		r/min
12	Mean effective pressure		MPa
13	Mean indicated pressure		MPa
14	Maximum cylinder pressure (gauge)		MPa
15	Charge air pressure (gauge, before inlet valves or scavenge ports, whichever applies)		MPa
16	Nominal compression ratio		–
17	Number of cylinders		–
18	Diameter of cylinders		mm

19	Length of piston stroke		mm
20	Length of connecting rod (between bearing centres)		mm
21	Oscillating Mass of one cylinder (mass of piston, rings,pin, piston rod,crosshead, oscillating part of connecting rod)		kg
22	Digitized gas pressure curve presented at equidistant intervals [MPa/crank angle] (intervals not more than 5° CA)		
	Additional Data of V-type Engines		
23	V-angle α. (see Figure 1.3.1(1) of this Appendix)		deg
	For the Cylinder Bank with Articulated-type Connecting Rod (see Figure 1.3.1(2) of this Appendix)		
24	Maximum cylinder pressure (gauge)		MPa
25	Charge air pressure (gauge, before inlet valves or scavenge ports)		MPa
26	Nominal compression ratio		–
27	Articulated-type connecting rod (see Figure 1.3.1(2) of this Appendix)		
28	Distance to link point L_A		mm
29	Link angle a_N		deg
30	Length of connecting rod L_N		mm
31	Oscillating Mass of one cylinder (mass of piston, rings,pin, piston rod,crosshead, oscillating part of connecting rod)		kg
32	Digitized gas pressure curve presented at equidistant intervals [MPa/crank angle] (intervals not more than 5° CA)		
	For the Cylinder Bank with Inner Connecting Rod		
33	Oscillating Mass of one cylinder (mass of piston, rings,pin, piston rod,crosshead, oscillating part of connecting rod)		kg
	Data of Crankshaft (see Figures 2.3.1(1), (2) and 2.4.1(3) of this Appendix) Note: For asymmetric cranks the dimensions are to be entered both for the left and right part of crank throw		
34	Drawing No.		
35	Kind of crankshaft (e.g. solid-forged crankshaft, semi-built crankshaft, etc.)		
36	Method of manufacture (e.g. free form forged, cast steel, etc.)		
37	Heat treatment (e.g. tempered)		
38	Surface treatment of fillets, journals and pins (e.g. nitrided, rolled, etc.)		
39	For crank throw for in-line engine, see Figure 2.3.1(1) of this Appendix For crank throw for engine with 2 adjacent connecting rods, see Figure 2.3.1(2) of this Appendix For crank dimensions necessary for the calculation of stress concentration factors, see Figure 2.4.1(3) of this Appendix		
40	Crankpin diameter D_P		mm
41	Diameter of bore in crankpin D_{BH}		mm
42	Fillet radius of crankpin R_H		mm
43	Recess of crankpin T_H		mm
44	Journal diameter D_G		mm
45	Diameter of bore in journal D_{BG}		mm
46	Fillet radius of journal R_G		mm
47	Recess of journal T_G		mm
48	Web thickness W		mm
49	Web width B		mm
50	Bending length L_1		mm
51	Bending length L_2		mm
52	Bending length L		mm
53	Oil Bore Design ☐Safety margin against fatigue at the oil bores is not less than that acceptable in the fillets		
54	Diameter of oil bore		mm
55	Smallest edge radius of oil bore		mm
56	Surface roughness of oil bore fillet		μm
57	Inclination of oil bore axis related to shaft axis		deg
	Additional Data for Shrink-Fits of Semi-Built Crankshafts		
58	For crank throw of semi-built crankshaft, see Figure 4.1.1 of this Appendix		
59	Shrink diameter D_S		mm
60	Length of shrink-fit L_S		mm
61	Outside diameter of web D_A or twice the minimum distance x mm (the smaller value is to be entered)		mm
62	Amount of shrink-fit (upper and lower tolerances)		mm %
63	Maximum torque (ascertained according to 2.3.3 of this Appendix with consideration of the mean torque)		N·m
	Data of Crankshaft Material Note: Minimum values of mechanical properties of material obtained from longitudinal test specimens		
64	Material designation (according to DIN, AISI, etc.)		
65	Method of material melting process (e.g. open-hearth furnace, electric furnace, etc.)		
66	Tensile strength		MPa
67	Yield strength		MPa

68	Reduction in area at break		%
69	Elongation A_5		%
70	Impact energy – KV		J
71	Young's modulus		MPa
Additional Data for Journals of Semi-Built Crankshafts			
72	Material designation (according to DIN, AISI, etc.)		
73	Tensile strength		MPa
74	Yield strength		MPa
Data According to Calculation of Torsional Stresses Note: In case ISC is entrusted with carrying out a forced vibration calculation to determine the alternating torsional stresses to be expected in the engine and possibly in its shafting, the data according to calculation of torsional vibration are to be submitted			
75	Max. nominal alternating torsional stress (ascertained by means of a harmonic synthesis according to 2.3.3(1) of this Appendix and related to cross-sectional area of bored crank pin)		MPa
76	Engine speed (at which the max. nominal alternating torsional stress occurs)		r/min
77	Minimum engine speed (for which the harmonic synthesis was carried out)		r/min
Data of Stress Concentration Factors (S.C.F.) and/or Fatigue Strength Furnished by Reliable Measurements Note: To be filled in only when data for stress concentration factors and/or fatigue are furnished by the engine manufacturer on the basis of measurements. Full supporting details are to be enclosed.			
78	S.C.F. for bending in crankpin fillet α_B		
79	S.C.F. for torsion in crankpin fillet α_T		
80	S.C.F. for bending in journal fillet β_B		
81	S.C.F. for compressing in journal fillet β_Q		
82	S.C.F. for torsion in journal fillet β_T		
83	Allowable fatigue strength of crankshaft σ_{DW}		MPa

(2) When crankshaft diameter check formula is adopted, only following drawings and particulars are to be submitted for approval:

① crankshaft drawing which must contain all data in respect of the geometrical configuration of the crankshaft;
② type designation and kind of engine (in-line engine or V-type engine with adjacent connecting rods, forked connecting rod or articulated-type connecting rod);
③ two-stroke or four-stroke;
④ direction of rotation (see Figure 1.3.1(1));
⑤ firing order with the respective ignition intervals and V angle (see Figure 1.3.1(1));
⑥ rated power (kW);
⑦ rated speed (r/min);
⑧ mean effective pressure (MPa);
⑨ mean indicated pressure (MPa);
⑩ maximum cylinder pressure (MPa);
⑪ number of cylinders;
⑫ cylinder diameter (mm);
⑬ piston stroke (mm);
⑭ trademark of crank material;
⑮ tensile strength (MPa);
⑯ heat treatment;
⑰ polishing method of fillets and oil holes.

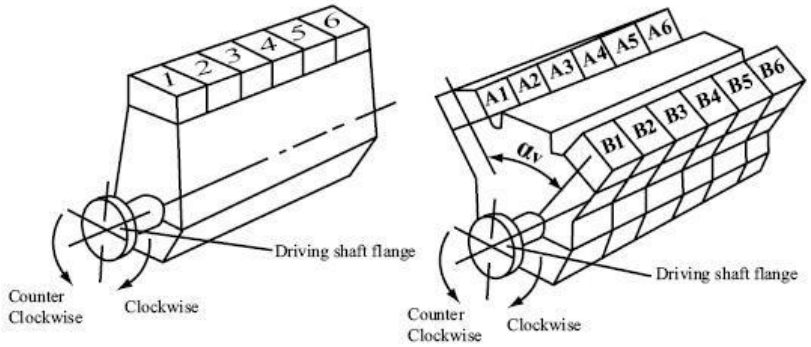

Figure 1.3.1(1) Designation of the Cylinders

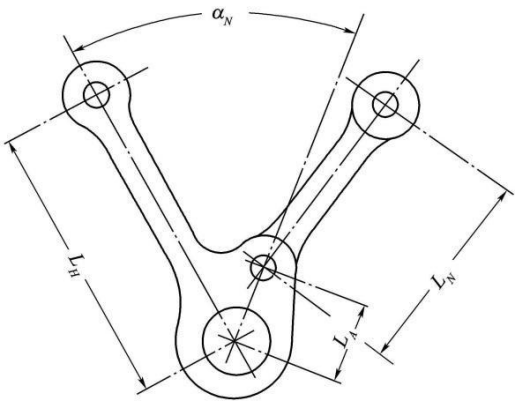

Figure 1.3.1(2) Articulated-Type Connecting Rod

1.3.2 Following particulars are to be submitted for information:
(1) Diesel engine manufacturers are to submit allowable torsional stresses, allowable longitudinal amplitudes (two-stroke), and values of crankshaft deflection regarding compulsory repairs for information.
(2) Diesel engine manufactures are to provide accurate equivalent parameters of torsional and longitudinal vibration and necessary instructions for shafting design and survey.

2 Check of Crankshaft Fatigue Strength (IACS)

2.1 Field of application

2.1.1 This calculation method applies only to solid-forged and semi-built crankshafts of forged or cast steel, with one crank throw between main bearings.

2.2 Principles of calculation

2.2.1 The calculation is based on the assumption that the areas exposed to highest stresses are:
(1) fillet transitions between the crankpin and web;
(2) fillet transitions between the journal and web;
(3) outlets of crankpin oil bores.
2.2.2 When journal diameter is equal or larger than the crankpin one, the outlets of main journal oil bores are to be formed in a similar way to the crankpin oil bores, otherwise separate documentation of fatigue safety may be required.
2.2.3 Calculation of crankshaft strength consists initially in determining the nominal alternating bending and nominal alternating torsional stresses which, multiplied by the appropriate stress concentration factors using the theory of constant energy of distortion, result in an equivalent alternating stress. This equivalent alternating stress is then compared with the fatigue strength of the selected crankshaft material. This comparison will then show whether or not the crankshaft concerned is dimensioned adequately.

2.3 Calculation of stresses

2.3.1 Calculation of nominal alternating stresses due to bending moments and radial forces
(1) Calculation of nominal alternating bending stress σ_{BN}
The calculation is based on a statically determined system, composed of one single crank throw supported in the centre of adjacent main journals. The bending length is taken as the length L between the two main bearing midpoints, see Figures 2.3.1(1) and 2.3.1(2) of this Appendix, and the imposed concentrated load is the radial force acting upon the crankpin due to connecting rod force. Radial forces are to be calculated in accordance with gas pressure from single cylinder, oscillating mass of piston mechanism, turning mass of cranks, mass and center of gravity of connecting rods, etc. The connecting rod force is to be obtained from calculation formula of diesel engine power, thus the radial force can be derived from the connecting rod force. At the same time, the maximum radial force F_{Rmax} (radial compression force acting on crank) and the minimum radial force F_{Rmin} (radial tension acting on crank) are to be found in one working cycle, so as to calculate the alternating radial force F_{BR} in one working cycle:

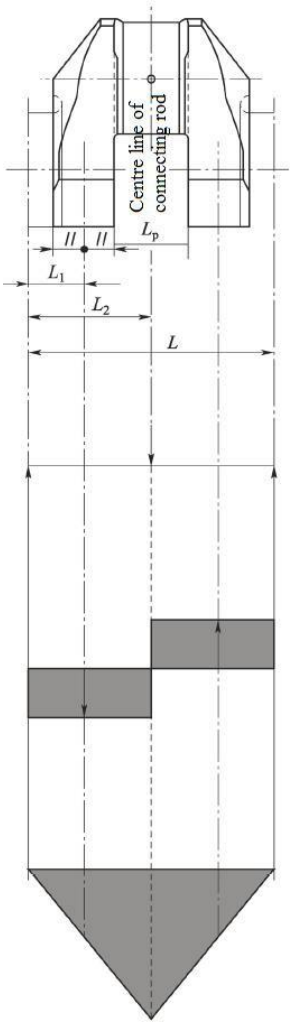

Figure 2.3.1(1)
Crank Throw for in Line Engine

Connecting-rod acting component forces (F_R or F_T)

Radial shear force diagrams (Q_R)

Bending moment diagrams (M_{BR} or M_{BT})

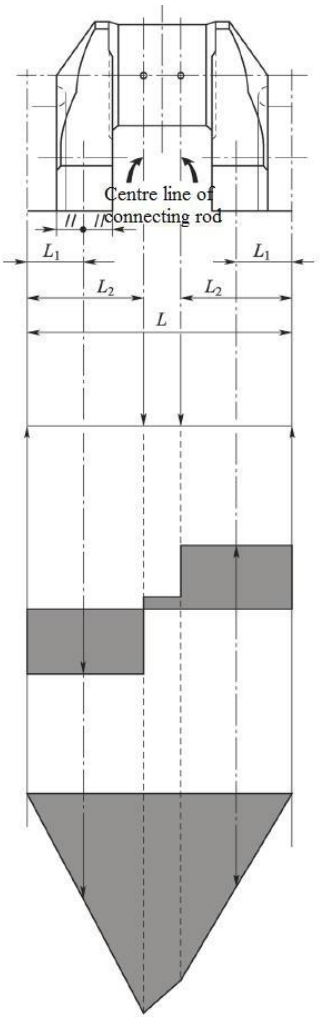

Figure 2.3.1(2)
Crank Throw for Vee Engine with 2 Adjacent Connecting Rods

$$F_{BR} = \pm\frac{1}{2}(F_{Rmax} - F_{Rmin}) \quad \text{N}$$

F_{BR} is the concentrated load of cranks, and its bending moment in way of the centerline of the crank web in the central cross section of crank is the nominal alternating bending moment M_{BN}, the value of which may be obtained by calculating the support reaction at the main bearing. In the case of the crank throw for in-line engines as shown in Figure 2.3.1(1), the support reaction at both main bearings is half the concentrated load F_{BR}, and then the nominal alternating bending moment M_{BN} in way of the centerline (L_1) of the crank web in the central cross section of crank is:

$$M_{BN} = \pm\frac{F_{BR}}{2}L_1 \times 10^{-3} \qquad \text{N·m}$$

The nominal alternating stresses due to bending moments and radial forces are to be related to the cross-sectional area of the crank web, and this cross-sectional area results from the web thickness W and the web width B. Figure 2.3.1(3) of this Appendix shows how W and B are to be measured in respect to overlapped crankshaft or crankshaft without overlap.

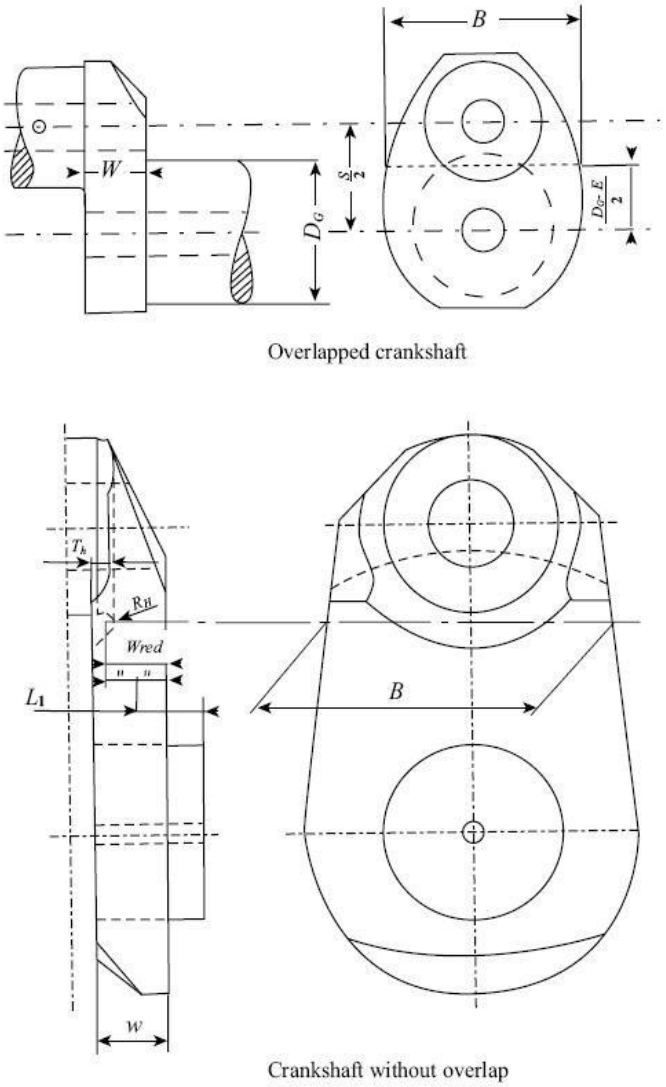

Figure 2.3.1(3) Reference Area of Crank Web Cross Section
(Symbols in the Figure are as defined in Figure 2.4.1(3) of this Appendix)

$$\sigma_{BN} = \pm \frac{M_{BN}}{W_{eq}} K_e \times 10^3 \qquad \text{MPa}$$

where: F_{BR} — alternating radial force, in N;
M_{BN} — nominal alternating bending moment, in N·m
L_1 — distance from main bearing centerline to crank web centerline, in mm, see Figures 2.3.1(1) and (2) of this Appendix;
K_e — empirical factor:
for two-stroke diesel engines $K_e = 0.80$;
for four-stroke diesel engines $K_e = 1.00$;
σ_{BN} — nominal alternating bending stress, in MPa;
$W_{eq} = \frac{BW^2}{6}$ mm^3.

For V-type diesel engines, two connecting rods act upon the same crankpin. The nominal alternating bending moments are to be taken as the bending moments of two triangular bending moments superposed according to phase, the differing designs (adjacent connecting rods, forked connecting rod or articulated-type connecting rod) being taken into account.
Where there are cranks of different geometrical configurations (e.g., asymmetric cranks) in one crankshaft, the calculation is to cover all crank variants.

(2) Calculation of nominal alternating compressive stress σ_{QN}

Radial forces resolved from the thrust of connecting rods are to be obtained in accordance with the simplified calculation method in 2.3.1(1). Radial force calculation table is to be listed in accordance with the formulae of diesel engine power, and a cylinder with maximum radial force value is to be found so as to gain nominal alternating radial force Q_N.

$$Q_N = \pm \frac{1}{2}(Q_{max} - Q_{min}) \quad \text{N}$$

$$\sigma_{QN} = \pm \frac{Q_N}{F} K_e \quad \text{MPa}$$

where: Q_{max} — maximum radial force of relevant cylinder, in N;

Q_{min} — minimum radial force of relevant cylinder, in N;

σ_{QN} — nominal alternating compressive stress due to radial force, in MPa;

$F = BW$, in mm^2.

(3) Calculation of nominal alternating bending stresses σ_{BO} in outlet of crankpin oil bore

The two relevant bending moments M_{BRO} and M_{BTO} are taken in the crankpin cross section through the oil bore (see Figure 2.3.1(4)), and the maximum moment M_{BOmax} and the minimum moment M_{BOmin} acting on the cross section are obtained by the superposition method to further determine the alternating bending moment M_{BON}:

$$M_{BO} = M_{BTO}\cos\psi + M_{BRO}\sin\psi \quad \text{N·m}$$

$$M_{BON} = \pm\frac{1}{2}\left[M_{BO_{max}} - M_{BO_{min}}\right] \quad \text{N·m}$$

where: ψ — angle between oil bore axis and tangential component of the connecting-rod force;

M_{BRO} — bending moment of the radial component of the connecting-rod force, in N·m;

M_{BTO} — bending moment of the tangential component of the connecting-rod force, in N·m.

The alternating bending stress σ_{BON} due to the alternating bending moment M_{BON} is to be related to the cross-sectional area of the axially bored crankpin, i.e.:

$$\sigma_{BON} = \pm\frac{M_{BON}}{W_e} \times 10^3 \quad \text{MPa}$$

The section modulus W_e of the crankpin cross section through the oil bore:

$$W_e = \frac{\pi}{32}\left[\frac{D_P^4 - D_{BH}^4}{D_P}\right] \quad \text{mm}^3$$

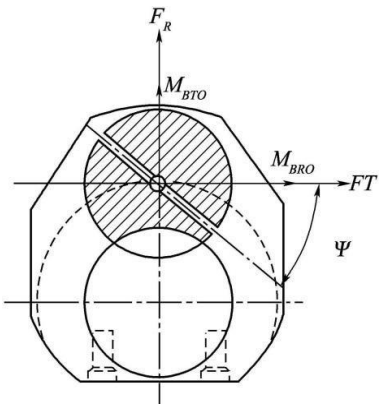

Figure 2.3.1(4) Crankpin section through the oil bore

2.3.2 Calculation of alternating bending stresses

The fillet transitions between the crankpin and web or between the journal and web as well as the outlets of crankpin oil bores are the areas exposed to the highest stresses. With the radial and tangential forces due to gas and inertia loads, the maximum alternating bending stresses will occur in the fillet or oil bore outlet.

(1) The alternating bending stress σ_{BH} in crankpin fillet

$$\sigma_{BH} = \pm(\alpha_B \sigma_{BN}) \quad \text{MPa}$$

where: α_B —stress concentration factor for bending in crankpin fillet (determination – see 2.4 of this Appendix).

(2) The alternating stress σ_{BG} in journal fillet

$$\sigma_{BG} = \pm(\beta_B \sigma_{BN} + \beta_Q \sigma_{QN}) \quad \text{MPa}$$

where: β_B —stress concentration factor for bending in journal fillet (determination n tion factorr for bending);

β_Q —stress concentration factor for compressing in journal fillet (determination – see 2.4 of this Appendix).

(3) The alternating bending stress σ_{BO} in the outlet of crankpin oil bores

$$\sigma_{BO} = \pm(\gamma_B \sigma_{BON}) \quad \text{MPa}$$

where: γ_B — stress concentration factor for bending in crankpin oil bore (determination – see 2.4 of this Appendix).

2.3.3 Calculation of alternating torsional stresses

(1) The calculation for nominal alternating torsional stress τ_N

The calculation for nominal alternating torsional stresses is to be undertaken by the engine manufacturer according to following provisions.

The calculation principle for nominal alternating torsional stresses is that the max. and min. alternating torques are to be ascertained for every mass point of the system and for the entire speed range by means of a harmonic synthesis of the forced vibrations from the 1st order up to and including the 15th order for two-stroke cycle engines and from the 0.5th order up to and including the 12th order for four-stroke cycle engines. Whilst doing so, allowance must be made for the damping that exists in the system and for unfavorable conditions, e.g. misfiring in one of the cylinders (misfiring is defined as cylinder condition when no combustion occurs but only compression cycle).

The nominal alternating torque M_T may be determined from above calculation:

$$M_T = \pm \frac{1}{2} (M_{T\max} - M_{T\min}) \quad \text{N·m}$$

Corresponding nominal alternating torsional stress τ_N is to be calculated by the following formula:

$$\tau_N = \pm \frac{M_T}{W_P} \times 10^3 \quad \text{MPa}$$

where: $W_P = \frac{\pi}{16} (\frac{D_P^4 - D_{BH}^4}{D_P})$, or $W_P = \frac{\pi}{16} (\frac{D_G^4 - D_{BG}^4}{D_G})$, mm^3;

$M_{T\max}$, $M_{T\min}$ — maximum and minimum valves of torque, in N·m.

(2) On determination of equivalent alternating stress σ_V, the maximum value gained from the calculation in 2.3.3(1) is to be adopted. Where barred speed ranges are arranged, the maximum value of the nominal alternating torsional stress occurring beyond is to be adopted. There are to be no barred speed ranges above a speed ratio of $\lambda \geq 0.8$ of the rated speed for normal firing conditions.

On calculation of crankshaft dimension, in the absence of such a maximum value, τ_N value is to be set as calculation basis. This assumption is based on the installation having the lowest acceptability factor, i.e., the calculation result is to satisfy $Q \geq 1.15$. Therefore, the pre-set τ_N value may be considered as ultimate value of torsional stress of the crankshaft. So far as the whole dynamic apparatus is concerned, provisions of the rules are also to be complied with, through appropriate calculation, so as to ensure that the approved nominal alternating torsional stress is not exceeded. The calculation is to be submitted for examination.

(3) Calculation of alternating torsional stresses τ_H in crankpin fillet:

$$\tau_H = \pm(\alpha_T \tau_N) \quad \text{MPa}$$

where: α_T —stress concentration factor for torsion in crankpin fillet (determination – see 2.4 of this Appendix).

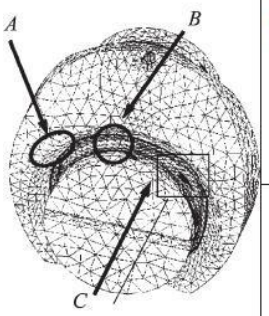
(4) The calculation of alternating torsional stress τ_G in journal fillet:

$$\tau_G = \pm (\beta_T \tau_N) \quad \text{MPa}$$

where: β_T — stress concentration factor for torsion in journal fillet (determination – see 2.4 of this Appendix).

$$\sigma_{TO} = \pm(\gamma_T \tau_N) \quad \text{MPa}$$

(5) The calculation of alternating torsional stress σ_{TO} in crankpin oil bore:



where: γ_T — stress concentration factor for torsion in outlet of crankpin oil bore (determination – see 2.4 of this Appendix).

2.4 Calculation of stress concentration factors

2.4.1 General requirements

(1) The stress concentration factors for bending (α_B, β_B) is defined as the ratio of the maximum bending stress occurring in the fillets under bending load acting in the central cross section of a crank to the nominal stress related to the web cross section (see Figure 2.4.1(1)).
The nominal stress is to be determined under the bending moment in the middle of the solid web.
(2) The stress concentration factor for torsion (α_T, β_T) is defined as the ratio of the maximum torsional stress – occurring under torsional load in the fillets – to the nominal stress related to the bored crankpin or journal cross-section (see Figure 2.4.1(1)).
(3) The stress concentration factor for compressing (β_Q) is defined as the ratio of the maximum compressive stress – occurring in the journal fillet under bending load – to the nominal compressive stress related to the web cross section.
(4) The stress concentration factors for bending (γ_B) and torsion (γ_T) are defined as the ratio of the maximum principal stress – occurring at the outlet of the crankpin oil bore under bending and torsional loads – to the corresponding nominal stress related to the axially bored crankpin cross section (see Figure 2.4.1(2)).
(5) The stress concentration factors may be evaluated by means of the formulae in accordance with 2.4.2, 2.4.3 and 2.4.4 of this Appendix applicable to the fillets and crankpin oil bores of solid-forged web-type crankshafts and to the crankpin fillets of semi-built crankshafts only. Stress concentration factor formulae concerning the oil bore are only applicable to a radially drilled oil bore.
(6) Where there are reliable measurement and/or calculation methods, direct assessment of Stress Concentration Factor (SCF) may be carried out, and relevant documents and analysis methods are to be submitted to ISC to prove that the adopted SCF calculation method is equivalent to the existing rule requirements. Where the geometry of crankshafts is outside the boundaries as specified in 2.4.1(8), (9) and (10), the stress concentration factors may be calculated by the method as specified in 2.4.5 and Annex III of this Appendix.
(7) All crank dimensions necessary for the calculation of stress concentration factors are shown in Figure 2.4.1(3).

Definition of Stress Concentration Factors in Crankshaft Fillets

	Stress	Max$\|\sigma_3\|$	Maxσ_1	
Torsional loading	Location of maximal stresses	*A*	*C*	*B*
	Typical principal stress system Mohr's circle diagram with $\sigma_2 = 0$	τ, σ; σ_3 σ_2 σ_1; $\|\sigma_3\| > \sigma_1$	τ, σ; σ_3 σ_2 σ_1; $\sigma_1 > \|\sigma_3\|$	τ, σ; σ_3 σ_2 σ_1; $\sigma_1 \approx \|\sigma_3\|$
	Equivalent stress and S.C.F	$\tau_{equiv} = \frac{\sigma_1 - \sigma_3}{2}$ S.C.F.$= \frac{\tau_{equiv}}{\tau_n}$ for α_T, β_T		
Bending loading	Location of maximal stresses	*B*	*B*	*B*
	Typical principal stress system Mohr's circle diagram with $\sigma_3 = 0$	τ, σ; σ_3 σ_2 σ_1; $\sigma_2 \neq 0$		
	Equivalent stress and S.C.F	$\sigma_{equiv} = \sqrt{\sigma_1^2 + \sigma_2^2 - \sigma_1 \cdot \sigma_2}$ S.C.F.$= \frac{\sigma_{equiv}}{\sigma_n}$ for $\alpha_B, \beta_B, \beta_Q$		

Figure 2.4.1(1) Stress Concentration Factors in Crankshaft Fillets

Stress Concentration Factors and Stress Distribution at the Edge of Oil Drillings

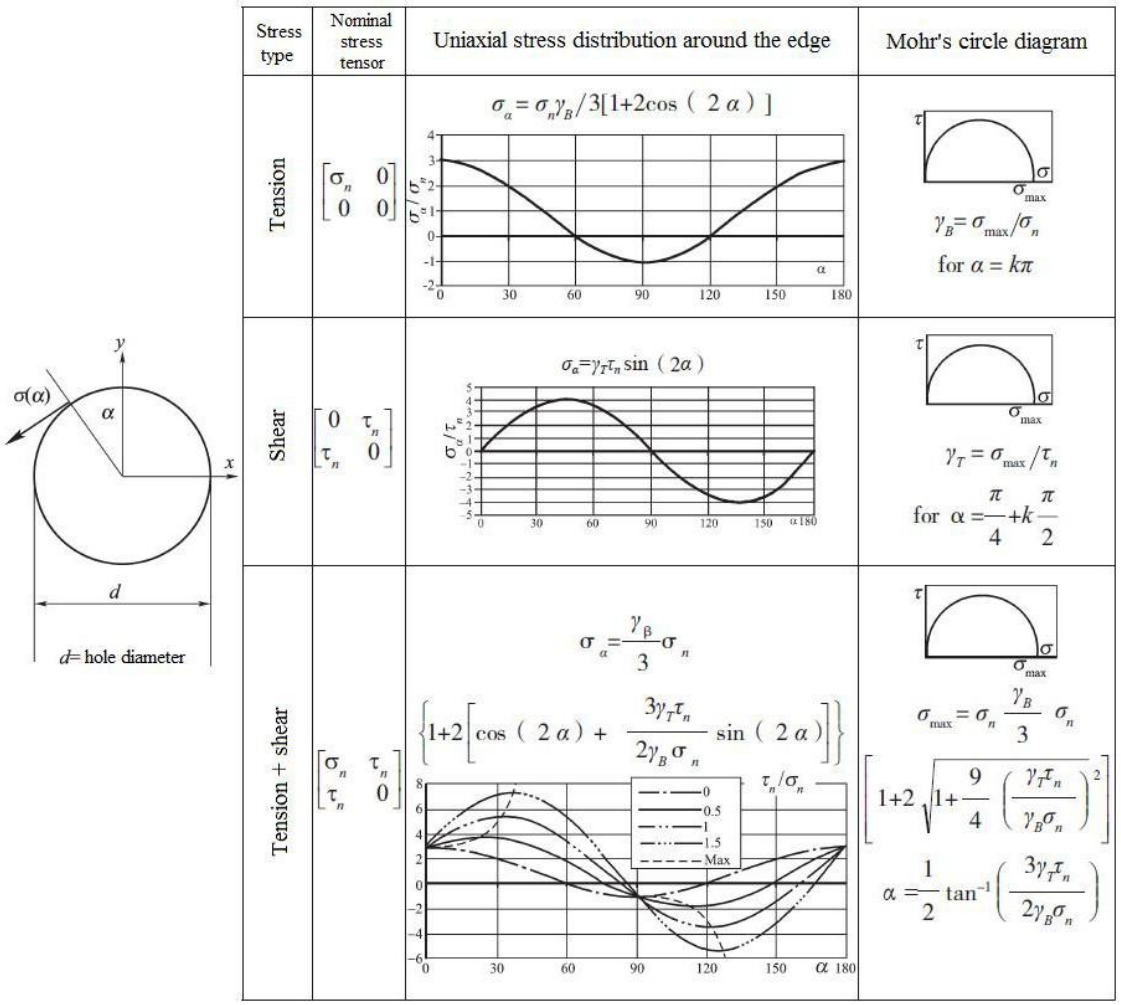


Figure 2.4.1(2) Stress Concentration Factors and Stress Distribution of Oil Drillings

Actual dimensions in the Figure:

D_P — crankpin diameter, in mm;

D_{BH} — diameter of bore in crankpin, in mm;

D_O — diameter of oil bore in crankpin, in mm;

R_H — fillet radius of crankpin, in mm;

T_H — recess of crankpin, in mm;

D_G — journal diameter, in mm;

D_{BG} — diameter of bore in journal, in mm;

R_G — fillet radius of journal, in mm;

T_G — recess of journal, in mm;

S — piston stroke, in mm;

E — journal overlap, $E = \frac{D_P + D_G}{2} - \frac{S}{2}$, in mm;

W — web thickness, in mm; in the case of 2 stroke semi-built crankshafts without journal overlap and when $T_H > R_H$, the web thickness must be considered as equal to $W_{red} = W - (T_H - R_H)$ (refer to Figure 2.3.1(3) of this Appendix);

B — web width, in mm; in the case of 2 stroke semi-built crankshafts without journal overlap, web width B is to be taken in way of crankpin fillet radius centre (refer to Figure 2.3.1(3) of this Appendix).

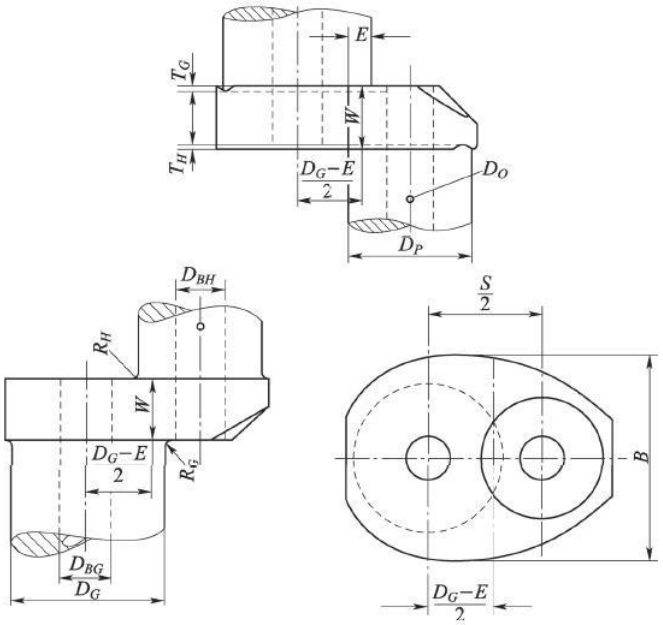

Figure 2.4.1(3)

Crank Dimensions Necessary for the Calculation of Stress Concentration Factors in Crank Throws

(8) The following related dimensions in Table 2.4.1 will be applied for the calculation of stress concentration factors.

(9) Stress concentration factors are valid for the ranges of related dimensions for which the investigations have been carried out. Ranges are as follows:

$$e \leq 0.5$$
$$0.2 \leq w \leq 0.8$$
$$1.1 \leq b \leq 2.2$$
$$0.03 \leq r \leq 0.13$$
$$0 \leq d_G \leq 0.8$$
$$0 \leq d_H \leq 0.8$$
$$0 \leq d_O \leq 0.2$$

(10) Low range of e can be extended down to large negative values provided that:

a. If calculated f (rec) < 1 then the factor f (rec) is not to be considered (f (rec) = 1);

b. If e < -0.5 then f (e, w) and f (r, e) are to be evaluated replacing actual value of e by -0.5.

Table 2.4.1

Crankpin fillet	Journal fillet
$r = R_H/D_P$	$r = R_G/D_P$
$e = E/D_P$	
w① $= W/D_P$	
$b = B/D_P$	
$d_O = D_o/D_P$	
$d_G = D_{BG}/D_P$	
$d_H = D_{BH}/D_P$	
$t_H = T_H/D_P$	
$t_G = T_G/D_P$	

Note: ① This applies to crankshafts with overlap. For crankshafts without overlap, $w = W_{red}/D_P$.

2.4.2 Calculation of the stress concentration factor for crankpin

(1) The stress concentration factor α_B for bending:

$$\alpha_B = 2.6914 f(e,w) f(w) f(b) f(r) f(d_G) f(d_H) f(rec)$$

where:

$$f(e,w) = -4.1883 + 29.2004w - 77.5925w^2 + 91.9454w^3 - 40.0416w^4 + (1-e)(9.544 - 58.348w + 159.3415w^2 - 192.5846w^3 + 85.2916w^4) - (1-e)^2(3.8399 - 25.0444w + 70.5571w^2 - 87.0328w^3 + 39.1832w^4);$$

$$f(w) = 2.179w^{0.7171};$$

$$f(b) = 0.684 - 0.0077b + 0.1473b^2;$$

$$f(r) = 0.2081r^{-0.5231};$$

$$f(d_G) = 0.9993 + 0.27d_G - 1.0211d_G^2 + 0.5306d_G^3;$$

$$f(d_H) = 0.9978 + 0.3145d_H - 1.5241d_H^2 + 2.4147d_H^3;$$

$$f(rec) = 1 + (t_H + t_G)(1.8 + 3.2e).$$

(2) Stress concentration factor α_T for torsion:

$$\alpha_T = 0.8 f(r,e) f(b) f(w)$$

where: $f(r,e) = r^{-(0.2205+0.1015e)}$;

$$f(b) = 7.8955 - 10.654b + 5.3482b^2 - 0.857b^3;$$

$$f(w) = w^{-0.145}.$$

2.4.3 Calculation of stress concentration factor for journal

(1) The stress concentration factor β_B for bending:

$$\beta_B = 2.7146 f_B(e,w) f_B(w) f_B(b) f_B(r) f_B(d_G) f_B(d_H) f(rec)$$

where:

$$f_B(e,w) = -1.7625 + 2.9821w - 1.5276w^2 + (1-e)(5.1169 - 5.8089w + 3.1391w^2) + (1-e)^2(-2.1567 + 2.3297w - 1.2952w^2);$$

$$f_B(w) = 2.2422w^{0.7548};$$

$$f_B(b) = 0.5616 + 0.1197b + 0.1176b^2;$$

$$f_B(r) = 0.1908r^{-0.5568};$$

$$f_B(d_G) = 1.0012 - 0.6441d_G + 1.2265d_G^2;$$

$$f_B(d_H) = 1.0022 - 0.1903d_H + 0.0073d_H^2;$$

$$f(rec) = 1 + (t_H + t_G)(1.8 + 3.2e).$$

(2) The stress concentration factor β_Q for compressing:

$$\beta_Q = 3.0128 f_Q(e) f_Q(w) f_Q(b) f_Q(r) f_Q(d_H) f_Q(rec)$$

where: $f_Q(e) = 0.4368 + 2.163(1-e) - 1.5212$（1-$e$）^{2};

$$f_Q(w) = \frac{w}{0.0637 + 0.9369w};$$

$$f_Q(b) = b - 0.5;$$

$$f_Q(r) = 0.5331r^{-0.2038};$$

$$f_Q(d_H) = 0.9937 - 1.1949d_H + 1.7373d_H^2;$$

$$f(rec) = 1 + (t_H + t_G)(1.8 + 3.2e).$$

(3) The stress concentration factor β_T for torsion:

If the diameters and fillet radii of crankpin and journal are the same:

$$\beta_T = \alpha_T$$

If crankpin and journal diameters and/or radii are of different sizes:

$$\beta_T = 0.8 f(r,e) f(b) f(w)$$

For $f(r, e)$, $f(b)$, $f(w)$, see the calculation of α_T, however, the radius of the journal fillet is to be related to the journal diameter:

$$r = \frac{R_G}{D_G}$$

2.4.4 Calculation of stress concentration factor for outlet of crankpin oil bore

(1) The stress concentration factor γ_B for bending:

$$\gamma_B = 3 - 5.88 d_O + 34.6 d_O^{\ 2}$$

(2) The stress concentration factor γ_T for torsion:

$$\gamma_T = 4 - 6 d_O + 30 d_O^{\ 2}$$

2.4.5 Calculation of stress concentration factors by means of finite element method

(1) General requirements

The formulae for the calculation of Stress Concentration Factors (SCF) in the crankshaft fillets as specified in 2.4.2, 2.4.3 and 2.4.4 of this Appendix are based on empirical formulae developed from strain gauge measurements of various crank geometries and accordingly the application of the formulae is limited to those geometries. Where the geometry of crankshafts is outside the boundaries as specified in 2.4.1(8) and (9), the SCF may be obtained as the ratio of stresses calculated by FEM to nominal stresses in both journal and pin fillets. When used in connection with the present method in this Appendix or the alternative methods, equivalent stresses are to be calculated for bending and principal stresses for torsion.

The procedure as well as evaluation guidelines of this Section are valid for both solid cranks and semi-built cranks (except journal fillets).

The analysis is to be conducted as linear elastic FE analysis, and unit loads of appropriate magnitude are to be applied for all load cases.

Prior to FE analysis, it is advised to check the element accuracy of the FE solver in use, e.g. by modeling a simple geometry and comparing the stresses obtained by FEM with the analytical solution for pure bending and torsion.

(2) Model requirements

The basic requirements for building the FE-model are presented in ① below. The material properties required for FE analysis are given in ② below. The FE-model is to comply with the element mesh quality criteria as specified in ③ below.

① Element mesh requirements

In order to fulfil the mesh quality criteria, the FE model is to be constructed in accordance with the following requirements:

—The FE model consists of one complete crank, from the main bearing centerline to the opposite side main bearing centerline.

—Element types used in the vicinity of the fillets include 10 node tetrahedral elements, 8 node hexahedral elements and 20 node hexahedral elements.

—Mesh properties in fillet radii and the element mesh of ±90° in circumferential direction from the crank plane are to comply with the following requirements:

- Maximum element size $a = r/4$ through the entire fillet as well as in the circumferential direction. When using 20 node hexahedral elements, the element size in the circumferential direction may be extended up to $5a$ (where r is fillet radius). In the case of multi-radii fillet r is the local fillet radius. (If 8 node hexahedral elements are used even smaller element size is required to meet the quality criteria.)
- Recommended manner for element size in fillet depth direction is as follows: first layer thickness equal to element size of a; second layer thickness equal to element to size of $2a$; third layer thickness equal to element to size of $3a$.
- Minimum 6 elements across web thickness.

—Generally the rest of the crank is to be suitable for numeric stability of the solver.

—Counterweights have to be modeled only when influencing the global stiffness of the crank significantly.

—Modeling of oil drillings is not necessary as long as the influence on global stiffness is negligible and the proximity to the fillet is more than $2r$, see Figure 2.4.5(1).

—Drillings and holes for weight reduction have to be modeled.

—Sub-modeling may be used as far as the software requirements are fulfilled.

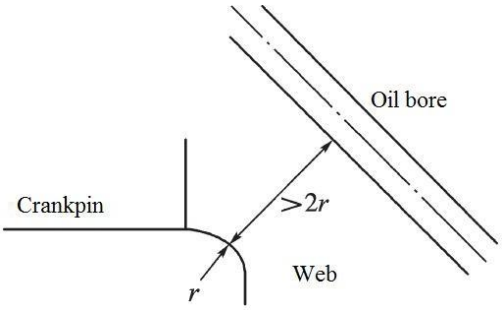

Figure 2.4.5(1) Oil Bore Proximity to Fillet

② Material

In FE analysis, the material properties such as Young's Modulus (E) and Poisson's ratio (ν) are required, as strain is primarily calculated and stress is derived from strain using the Young's Modulus and Poisson's ratio. Reliable values for material parameters have to be used, either as quoted in literature or as measured on representative material samples.

For steel the following Young's Modulus (E) and Poisson's ratio (ν) are advised:

$E = 2.05 \cdot 10^5$ MPa

$\nu = 0.3$.

③ Element mesh quality criteria

If the actual element mesh does not fulfil any of the following criteria at the examined area for SCF evaluation, then a second calculation with a refined mesh is to be performed.

—Principal stresses criterion

The quality of the mesh is to be assured by checking the stress component normal to the surface of the fillet radius. Ideally, this stress is to be zero. With principal stresses σ_1, σ_2 and σ_3 the following criterion is required:

$$\min\left(|\sigma_1|,|\sigma_2|,|\sigma_3|\right) < 0.03 \max\left(|\sigma_1|,|\sigma_2|,|\sigma_3|\right)$$

—Averaged/unaveraged stresses criterion

The criterion is based on observing the discontinuity of stress results over elements at the fillet for the calculation of SCF. unaveraged nodal stress results calculated from each element connected to a node$_i$ should differ less than by 5 % from the 100 % averaged nodal stress results at this node$_i$ at the examined location.

(3) Load cases

The following load cases are to be considered when stress concentration factors are calculated by FEM.

① Torsion

In analogy to the testing apparatus used for the investigations made by FVV the structure is loaded pure torsion. In the model surface warp at the end faces is suppressed. Torque is applied to the central node located at the crankshaft axis. This node acts as the master node with 6 degrees of freedom and is connected rigidly to all nodes of the end face (see Figure 2.4.5(2)).

Boundary and load conditions as shown in Figure 2.4.5(2) are valid for both in-line and V-type engines.

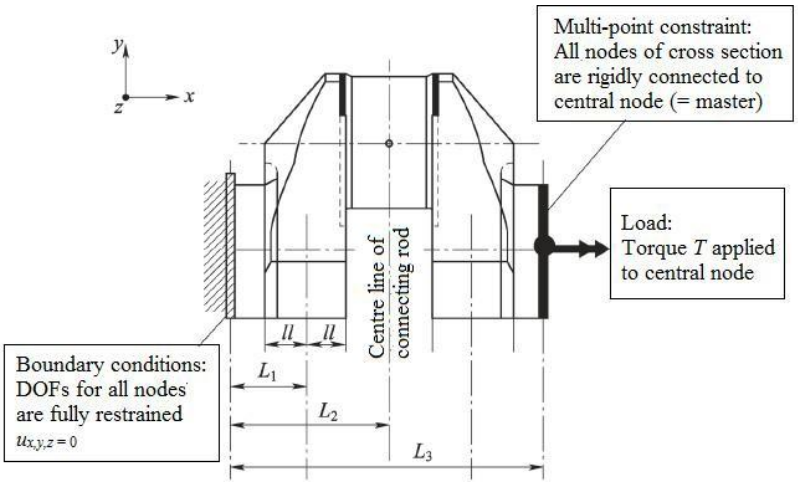

Figure 2.4.5(2) Boundary and Load Conditions for the Torsion Load Case

For all nodes in both the journal and crank pin fillet principal stresses are extracted and the equivalent torsional stress τ_{equiv} is calculated in accordance with the following formula:

$$\tau_{equiv} = \max\left(\frac{|\sigma_1 - \sigma_2|}{2}, \frac{|\sigma_2 - \sigma_3|}{2}, \frac{|\sigma_1 - \sigma_3|}{2}\right) \quad \text{MPa}$$

The maximum value taken for the subsequent calculation of the stress concentration factors α_T and β_T in the crank pin and journal fillet respectively as follows:

$$\alpha_T = \frac{\tau_{equiv,\alpha}}{\tau_N}$$

$$\beta_T = \frac{\tau_{equiv,\phi}}{\tau_N}$$

where: τ_N—nominal torsional stress calculated in accordance with 2.3.3, in MPa;

$\tau_{equiv,\alpha}, \tau_{equiv,\beta}$—maximum equivalent torsional stress in the crank pin and journal fillet, in MPa.

② Pure bending

In analogy to the testing apparatus used for the investigations made by FVV the structure is loaded in pure bending. In the model surface warp at the end faces is suppressed. The bending moment is applied to the central node located at the crankshaft axis. This node acts as the master node with 6 degrees of freedom and is connected rigidly to all nodes of the end face (see Figure 2.4.5(3)).

Boundary and load conditions as shown in Figure 2.4.5(3) are valid for both in-line and V-type engines.

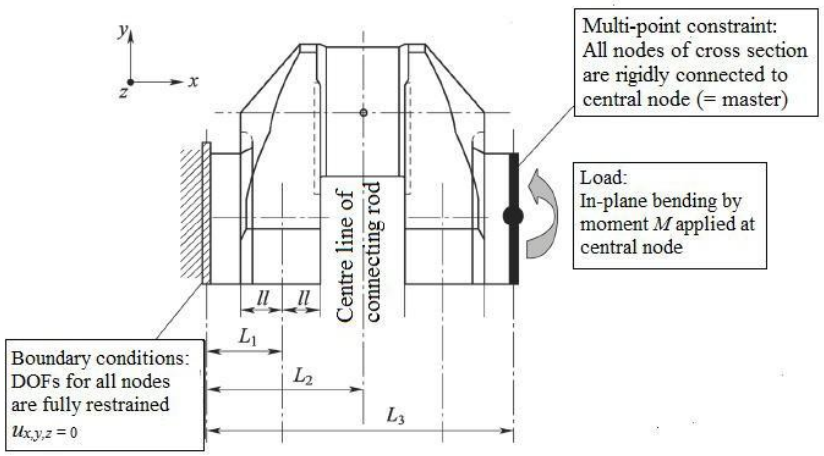

Figure 2.4.5(3) Boundary and Load Conditions for the Pure Bending Load Case

For all nodes in both the journal and pin fillet, the equivalent stresses are extracted. The maximum value is used to calculate the stress concentration factors α_B and β_B according to the following formulae:

$$\alpha_B = \frac{\sigma_{equiv,\alpha}}{\sigma_{BN}}$$

$$\beta_B = \frac{\sigma_{equiv,\beta}}{\sigma_{BN}}$$

where: σ_{BN} —nominal alternating bending stress calculated in accordance with 2.3.1(1), in MPa;

$\sigma_{equiv,\alpha}, \sigma_{equiv,\beta}$—maximum equivalent stress in the crank pin and journal fillet, in MPa.

③ Bending with shear force

This load case is calculated to determine the stress concentration factor for compressive stress β_Q for the journal fillet.

In analogy to the testing apparatus used for the investigations made by FVV, the structure is loaded in 3-point bending. In the model, surface warp at the both end faces is suppressed. All nodes are connected rigidly to the centre node; boundary conditions are applied to the centre nodes. These nodes act as master nodes with 6 degrees of freedom. The force is applied to the central node located at the pin centre-line of the connecting rod (see Figure 2.4.5(5)). This node is connected to all nodes of the pin cross sectional area. Warping of the sectional area is not suppressed.

Boundary and load conditions as shown in Figure 2.4.5(4) are valid for in-line and V-type engines. V-type engines can be modeled with one connecting rod force only. Using two connecting rod forces will make no significant change in the SCF.

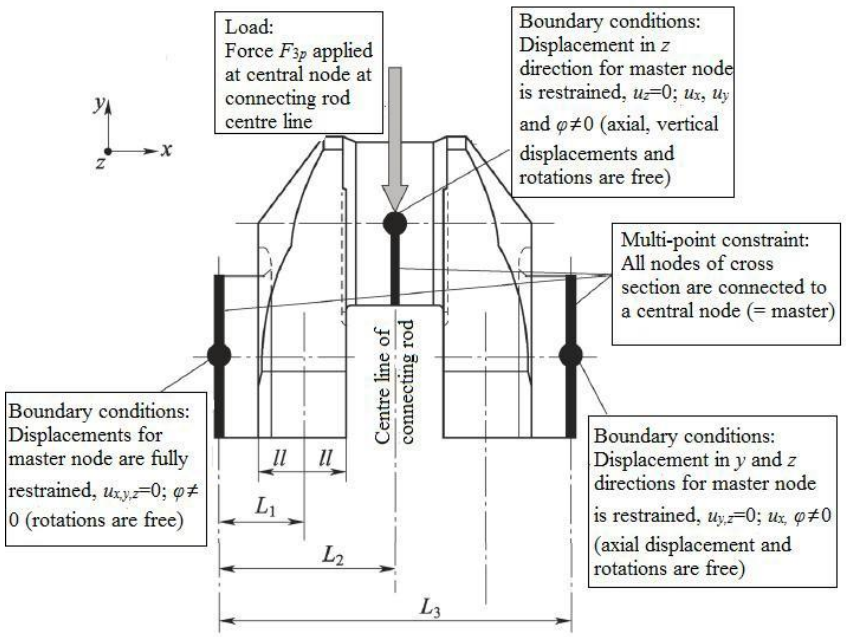

Figure 2.4.5(4) Boundary and Load Conditions for the 3-point Bending Load Case of an In-line Engine

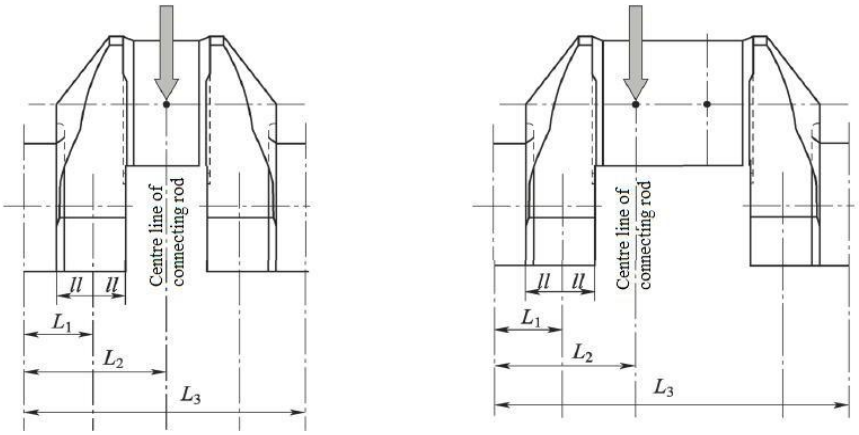

Figure 2.4.5(5) Load Applications for In-line and V-type Engines

The maximum equivalent stress σ_{3P} in the journal fillet is evaluated. The stress concentration factors in the journal fillet can be determined in two ways as shown below.

— Method 1. This method is analogue to the FVV investigation. The results from pure bending and bending with shear force in the journal fillet are combined as follows:

$$\sigma_{3P} = \beta_B \sigma_{N3P} + \beta_Q \sigma_{Q3P} \quad \text{MPa}$$

The stress concentration factor β_Q is calculated as follows:

$$\beta_Q = \frac{\sigma_{3P} - \beta_B \sigma_{N3P}}{\sigma_{Q3P}}$$

where: σ_{3P} — maximum equivalent stress as found by the FE calculation, in MPa;

σ_{N3P} — nominal bending stress in the web centre due to the force F_{3P} applied to the centre-line of the actual connecting rod, in MPa, see Figure 2.4.5(5);

β_B — stress concentration factor for bending in the journal fillet under pure bending load, as determined in 2.4.5(3)②;

σ_{Q3P} — nominal compressive stress due to radial (shear) force Q_{3P} in the web due to the force F_{3P} applied to the centre-line of the actual connecting rod, in MPa (see Figures 2.1.3(1) and (2)). $\sigma_{Q3P} = Q_{3P}/(BW)$, where B and W are web width and thickness respectively.

— Method 2. This method is not analogous to the FVV investigation. In a statically determined system with one crank throw supported by two bearings, the bending moment and radial (shear) force are proportional. Therefore the journal fillet stress concentration factor β_{BQ} can be found directly by the 3-point bending FE calculation.

$$\beta_{BQ} = \frac{\sigma_{3P}}{\sigma_{N3P}}$$

For symbols see Method 1.

When using Method 2 the radial force and stress becomes superfluous. The alternating bending stress σ_{BG} in the journal fillet as per 2.3.2(2) is calculated in accordance with the following formula:

$$\sigma_{BG} = \pm \left| \beta_{BQ} \sigma_{BN} \right|$$

Note that the use of Method 2 does not apply to the crankpin fillet and that this SCF must not be used in connection with calculation methods other than those assuming a statically determined system as in this Appendix.

2.5 Determination of additional bending stresses σ_{add}

2.5.1 In addition to the alternating bending stresses in fillets caused by gas and inertia loads, additional bending stresses σ_{add} (additional bending stress σ_{aa} due to misalignment and bedplate deformation as well as

additional bending stress σ_{ax} due to axial vibrations) will cause crankshaft fatigue damage unless restriction is imposed or accurate determination made.
Additional bending stresses are as given in Table 2.5.1 to different engine types:

Table 2.5.1

Type of engine	σ_{add} (MPa)
Crosshead engines	± 30①
Trunk piston engines	± 10

Note: ① The additional stress of ±30 MPa is composed of two components: an additional stress of ±20 MPa resulting from axial vibration, an additional stress of ±10 MPa resulting from misalignment/bedplate deformation. It is recommended that a value of ±20 MPa be used for the axial vibration component for assessment purposes where axial vibration calculation results of the complete dynamic system are not available. Where axial vibration calculation results of the complete dynamic system are available, the calculated figures may be used instead.

2.5.2 According to the calculation, the appraisal of the crankshaft is based on the minimum acceptability factor Q (see 2.8 of this Appendix). Therefore, where $Q > 1.15$ with a certain margin, the allowable amplitude of axial vibrations may be raised corresponding to the maximum value of the allowable crankshaft deflection provided by the diesel engine manufacturer.

2.6 Calculation of equivalent alternating stress σ_v

2.6.1 For calculation of equivalent alternating stress σ_v in fillets, the theory of constant energy of distortion is to be used. In this case, it is assumed that the maximum alternating bending stresses and maximum alternating torsional stresses within a crankshaft occur simultaneously and at the same point.
At the oil hole outlet, bending and torsion lead to two different stress fields which can be represented by an equivalent principal stress equal to the maximum of principal stress resulting from combination of these two stress fields with the assumption that bending and torsion are time phased (see Figure 2.4.1(2) of this Appendix).

2.6.2 Equivalent alternating stress

The equivalent alternating stress σ_v is calculated in accordance with the formulae given.

For the crankpin fillet:

$$\sigma_v = \pm\sqrt{(\sigma_{BH} + \sigma_{add})^2 + 3\tau_H^2} \quad \text{MPa}$$

For the journal fillet:

$$\sigma_v = \quad t\sqrt{(\sigma_{BG} + \sigma_{add})^2 + 3\tau_G^2} \quad \text{MPa}$$

For crankpin oil bore outlet:

$$\sigma_v = \pm\frac{1}{3}\sigma_{BO}\left[1 + 2\sqrt{1 + \frac{9}{4}\left(\frac{\sigma_{TO}}{\sigma_{BO}}\right)^2}\right] \quad \text{MPa}$$

For other parameters, see 2.3 of this Appendix.

2.7 Calculation of fatigue strength

2.7.1 The fatigue strength is to be understood as that value of alternating bending stress which a crankshaft can permanently withstand at the most highly stressed points of the fillets. Where the fatigue strength for a crankshaft cannot be furnished by reliable measurements, the allowable fatigue strength σ_{DW} may be

Related to the crankpin diameter:

$$\sigma_{DW} = \pm K(0.42R_m + 39.3)\left[0.264 + 1.073D_P^{-0.2} + \frac{785 - R_m}{4900} + \frac{196}{R_m}\sqrt{\frac{1}{R_x}}\right] \quad \text{MPa}$$

with $R_x = R_H$ in the fillet area; $R_x = D_O/2$ in the oil bore area.

Related to the journal diameter:

$$\sigma_{DW} = \pm K(0.42R_m + 39.3)\left[0.264 + 1.073D_G^{-0.2} + \frac{785 - R_m}{4900} + \frac{196}{R_m}\sqrt{\frac{1}{R_G}}\right] \quad \text{MPa}$$

evaluated by means of the following formulae:

where: K — factor for different types of crankshafts without surface treatment. Values greater than 1 are only applicable to fatigue strength in fillet area:

= 1.05 for continuous grain flow forged or drop-forged crankshafts;
= 1.0 for free form forged crankshafts (without continuous grain flow);
= 0.93 for cast steel crankshafts (factor for cast steel crankshafts with cold rolling treatment in fillet area, using a ISC approved cold rolling process);

R_m — tensile strength of crankshaft material, in MPa.

For other parameters, see 2.4.1 of this Appendix.

These formulae are subject to the following conditions:

(1) surfaces of the fillet, the outlet of the oil bore and inside the oil bore (down to a minimum depth equal to 1.5 times the oil bore diameter) are to be smoothly finished;

(2) for calculation purposes RH, RG or Rx are to be taken as not less than 2 mm.

2.7.2 When a surface treatment process is applied, it is to be approved by ISC. The fatigue strength of fillets and outlets of oil bores that have been surface treated may be calculated according to the method specified in Annex II of this Appendix.

2.7.3 As an alternative, the fatigue strength of the crankshaft can be determined by experiment based either on full size crank throw (or crankshaft) or on specimens taken from a full size crank throw. The result of the fatigue test is to be evaluated according to the method specified in Annex I of this Appendix.

2.8 Acceptability criteria of a crankshaft

2.8.1 The sufficient dimensioning of a crankshaft is confirmed by a comparison of the equivalent alternating stress and the fatigue strength. This comparison through the acceptability factor Q is to be carried out for the crankpin fillet, the journal fillet, the outlet of crankpin oil bore and is based on the formula:

$$Q = \frac{\sigma_{DW}}{\sigma_V} \geq 1.15$$

2.8.2 The acceptability factor Q is not necessarily the safety factor of the crankshaft. It only stands for a value related to the calculation. The value of fatigue strength of the material is not the only cause for the damage of the crankshaft, which actually has something to do with the strained condition of the crankshaft. Where the crankshaft is excessively deformed, its reliability will be affected. However, the acceptability factor Q can also show the safety margin of the crankshaft itself, for the calculation is based on its torsional stress for appraisal of the crankshaft, combined with the bending stress concerned, so as to get the minimum acceptability factor. Therefore, where $Q > 1.15$ with a certain margin, the allowable values of torsional stress, axial vibration stress, crankshaft deflection regarding compulsory repairs are to be appropriately adjusted. This is useful to design, operation and survey.

2.9 Allowable values to be provided by manufacturers

2.9.1 Manufacturers are to provide the values of allowable torsional stresses, allowable axial amplitudes and crankshaft deflection regarding compulsory repairs.

2.9.2 The allowable values mentioned in 2.9.1 of this Appendix are to be taken as the relevant values on calculating Q in 2.8.1 of this Appendix, or to be taken as the limiting values concerned when $Q = 1.15$.

3 Calibration of Crankshaft Diameter

3.1 Scope

3.1.1 The calculation is applicable to crankshafts of in-line and V-diesel engines. These crankshafts have an equal span of bearings adjacent to cranks, and are made of forged steel, cast steel, alloy steel or nodular graphite cast iron.

3.2 Calculation principles

3.2.1 The calculation is also based on the assumption that the fillet transitions between the journal and web are the crankshaft areas to the highest stresses. It is the most concentrated stress area and the fatigue damage of the crankshafts is most probably to happen here.

3.2.2 Crankshaft strength calibration is based on the theory of maximum normal stress. This calculation is assuming that the damage of crankshaft is due to the combined action of the maximum bending moment (bending stress) and maximum torque (shearing stress) upon it. Therefore, the maximum bending moment and the maximum torque (multiplying relevant stress concentration factors) are to be combined to the maximum equivalent bending moment. By fatigue strength of material and adequate safety factors, the calculation formula of the minimum diameter necessary for the crankshafts can be inferred.

3.3 Calculation of the minimum diameter of the crankshafts

3.3.1 The specified tensile strength of forgings and castings for crankshafts is in general to be selected within the following scope and in compliance with the relevant requirements of ISC Rules for Materials and Welding.

(1) Carbon and carbon-manganese steel 400 to 600 MPa;
(2) Alloy steel 600 to 1,000 MPa;
(3) Nodular graphite cast iron 490 to 780 MPa.

3.3.2 The minimum diameter D_P (or D_G) of the crankpins or the journals of fully-built or semi-built crankshafts is to be calculated by the following.

For crankshafts made of forged steel, cast steel and alloy steel:

$$D_P = \sqrt[3]{\frac{D^2\left[Aa_B p_z (L - L_p) + Ca_T p_i S\right]}{65 \times (\frac{R_m + 160}{560})}} \quad \text{mm}$$

For crankshafts made of nodular graphite cast iron:

$$D_P = \sqrt[3]{\frac{D^2\left[Aa_B p_z (L - L_p) + Ca_T p_i S\right]}{59 \times (0.3 + \frac{0.7R_m}{490})}} \quad \text{mm}$$

where: D — cylinder diameter, in mm;
S — piston stroke, in mm;
L — span of adjacent bearings measured from center to center, in mm;
L_P — length of crankpin, in mm;
p_z — maximum combustion pressure, in MPa;
p_i — mean indicated pressure, in MPa;
R_m — tensile strength of the material used, in MPa;
A — coefficient:
for single acting in-line diesel engines, A = 0.50;
for two-stroke V-diesel engines, A is to be selected in accordance with Table 3.3.2(1);
for four-stroke V-diesel engines, A is to be selected in accordance with Table 3.3.2(2);
C — coefficient:
for single acting in-line diesel engines, C is to be selected in accordance with Table 3.3.2(3);
for two-stroke V-diesel engines, C is to be selected in accordance with Table 3.3.2(4);
for four-stroke V-diesel engines, C is to be selected in accordance with Table 3.3.2(5);
α_B — bending stress concentration factor;
α_T — torsional stress concentration factor.

3.3.3 Calculation and application of stress concentration factor

(1) Fracture of the diesel engine crankshafts is most probably caused by fatigue. When in bending fracture, fatigue appears mostly in the transition fillets between the crankpin and web or between journal and web. This is because the stress here is most concentrated. Therefore, the so called bending stress concentration factor means the ratio of the maximum bending stress occurring in the transition fillets of the crankpins under bending load acting in the central cross-section of a crank to the nominal bending stress related to the crankpin cross-section. The nominal bending stress is to be determined under the bending moment in the middle of the solid web.

(2) Torsional stress concentration factor means the ratio of the maximum torsional stress under the torsional load in the fillets to the nominal torsional stress related to the crankpin cross-section.

(3) Fatigue damage of the crankshafts is related to the actual stress in the transition fillets acted by the operation of the diesel engines. The actual stresses include the additional stress caused by misalignment of the crankshafts and highly concentrated stress caused by the geometry of the crankshafts. Therefore, bending stress concentration factor is actually the surface features of this ingredient, which is obtained through quantitative study of three-directional photoelasticity test.

(4) The geometrical dimensions of the crankshafts affecting the stress concentration in fillets mainly include the radius of transition fillets R_H, web thickness W, web breadth B (for taking B, see Figure 2.3.1(1) of this Appendix), journal overlap E, diameter of journal cavity D_{BH}, recess depth of fillet T_H, etc., which are more or less affecting. Anyhow, to improve the applicability of stress concentration factor, the geometrical dimensions mentioned above corresponding to crankpin diameter D_P (or fillet radius R_H) turn to dimensionless relative dimension, i.e.:

$$r = R_H / D_P$$

$$w = W / D_P$$
$$b = B / D_P$$
$$e_k = 1 - E / D_P$$
$$d_H = D_{BH} / D_P$$
$$\delta = T_H / R_H$$

Only when the relative dimensions mentioned above are used in a specified range can the stress concentration factor be effective, and they are only applicable to the crankpins of fully-built or semi-built crankshafts. The applicable range of the relative dimensions is as follows:

$$0.03 \le r \le 0.10$$
$$0.25 \le w \le 0.60$$
$$1.30 \le b \le 2.00$$
$$0.50 \le e_k \le 1.50$$
$$0 \le d_H \le 0.70$$
$$0 \le \delta \le 0.65$$

The dimensions for the calculation of the stress concentration factor are shown in Figure 2.4.1(3).

(5) Bending stress concentration factor α_B is to be calculated as follows:

$$\alpha_B = 0.625 f_1(r)\, f_2(w)\, f_3(e_k, w)\, f_4(b)\, f_5(d_H)$$

where: $f_1(r)$, $f_2(w)$, $f_3(e_k, w)$, $f_4(b)$, $f_5(d_H)$ may be obtained from Figures 3.3.3(1), (2), (3)a, b, c and (4), (5). Where the transition fillets of the crankpins or journals are filleted arc and the recess depth is T_H (as shown in Figure 2.4.1(3)), α_B value is to multiply $f_6(\delta)$ value obtained from Table 3.3.2 (6).

(6) Torsional stress concentration factor α_T is to be obtained from Figure 3.3.3 (6).

4 Calculation of Shrink-fits of Semi-built Crankshafts

4.1 Geometry

4.1.1 All crank dimensions necessary for the calculation of shrink-fits are shown in Figure 4.1.1.

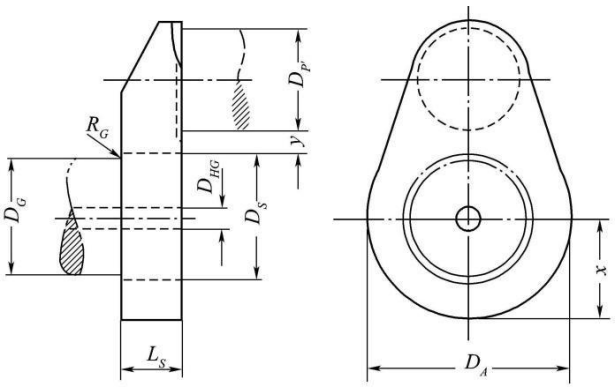

Figure 4.1.1 Crank Throw of Semi-built Crankshaft

where: D_S — shrink diameter, in mm;

L_S — length of shrink-fit, in mm;

D_A — outside diameter of web or twice the minimum distance x between centre-line of journals and outer edge of web, whichever is less, in mm;

y — distance between the adjacent generating lines of journal and pin.

$y \geq 0.05D_S$, in mm;

where y is less than $0.1D_S$, special consideration is to be given to the effect of the stress due to shrink on the fatigue strength at the crankpin fillet.

For other parameters, see 2.4.1 and Figure 2.4.1(3) of this Appendix.

4.1.2 For the arc radius of the journal transiting to the diameter of the shrink-fit, the following formulae are to be complied with:

$R_G \geq 0.015D_G$ and $R_G \geq 0.5(D_S - D_G)$, whichever is greater to be taken.

4.2 Maximum permissible hole diameter D_{BG} in the journal pin

4.2.1 In the case where the hole diameter in the journal pin is greater than the value obtained according to 4.2.2, then the calculation methods of minimum oversize Z_{min} and maximum oversize Z_{max} are not applicable to oversize of shrink-fit. In such case the maximum and minimum oversizes have to be established based on FEM calculations.

4.2.2 Calculation of maximum permissible hole diameter D_{BG}

The maximum permissible hole diameter D_{BG} in the journal pin is calculated in accordance with the following formula:

$$D_{BG} = D_S \cdot \sqrt{1 - \frac{4000 S_R M_{max}}{\mu \pi D_S^2 L_s R_{eH}}} \quad \text{mm}$$

where: S_R — safety factor against slipping, however a value not less than 2 is to be taken unless documented by experiments;

μ — coefficient for static friction, $\mu = 0.20$ for $L_S / D_S \geq 040$;

$M_{max} = M_T + 9.55 \frac{N_e}{n_e}$ N·m , where the maximum torque M_{max} corresponds to the maximum torque M_{Tmax} of mass points of the crankshaft determined in 2.3.3(1), i.e., after mean torque is considered, M_{max} may be obtained from nominal torque M_T (see 2.3.3(1)) and mean transfer torque of crankshaft;

R_{eH} — minimum yield strength of material for journal, in MPa;

N_e — rated power of diesel engines, in kW;

n_e — corresponding rated speed, in r/min.

4.3 Interference fit

4.3.1 Calculation of minimum oversize of shrink-fit

The minimum oversize of shrink-fit is to be determined by the greater value calculated in accordance with the formulae in 4.3.1(1) and 4.3.1(2).

(1) The minimum oversize of shrink-fit Z_{min} is to comply with the following formula:

$$Z_{min} \geq \frac{4 \times 10^3}{\pi \mu} \times \frac{S_R M_{max}}{E_m D_S L_S} \times \frac{1 - Q_A^2 Q_S^2}{(1 - Q_A^2)(1 - Q_S^2)} \quad \text{mm}$$

where: $Q_A = \frac{D_S}{D_A}$;

$Q_S = \frac{D_{BG}}{D_S}$;

E_m — Young's modulus, in MPa.

For other parameters, see 4.2.2 of this Appendix.

(2) Minimum oversize of shrink-fit Z_{min} is also to comply with the following formula:

$$Z_{min} \geq \frac{R_{eH} \cdot D_S}{E_m} \quad \text{mm}$$

where: R_{eH} — minimum yield strength of material for crank web, in MPa.

4.3.2 Determination of maximum permissible interference

The maximum interference of shrink-fit crankshaft is to limit the influence of the interference fit on mean stress in fillets. The maximum permissible interference Z_{max} may be calculated in accordance with the following:

$$Z_{max} \leq \frac{\delta_S D_S}{E_m} + \frac{0.8 D_S}{1000} \quad \text{mm}$$

5 Influence of Shafting on Crankshaft Strength

5.1 Summary

5.1.1 Crankshaft strength is not only related to crankshaft material, structure dimensions and technology, but also related to arrangement and installation of the whole shafting. During the stage of crankshaft design, fatigue strength of the crankshaft may be determined in accordance with the method in 2 of this Appendix, so that the allowable torsional stress, axial stress and compulsory repair span difference may be obtained.

5.1.2 During the stage of crankshaft design, the phenomena such as torsional vibration-axial vibration or torsion-longitudinal coupling vibration.

5.1.3 Where torsional antivibrator and/or axial antivibrator are installed, alternating torsional stress τ_H and additional axial bending stress σ_{ax} will be less than the values given in 2.3 and 2.5. Thus, the fatigue strength of the crankshaft may be increased.

5.1.4 Shafting arrangement and installation are to satisfy the requirements of torsional vibration, axial vibration and alignment as specified in rules and by the manufacturers. However, if one item is not in compliance with the specified value due to special condition, the actual value may be used in the fatigue acceptability factor Q. Where $Q \geq 1.15$ is still complied with, it is safe to the crankshaft. However attention is to be paid not to exceed the fatigue strength of the material.

5.2 Torsional vibration

5.2.1 To simplify calculation, the allowable torsional vibration stress specified by ISC Rules may be treated as τ_H.

5.2.2 Where the allowable torsional vibration stress provided by the manufacturer exceeds that specified in the Rules, calculation is to be submitted for review in accordance with the requirements of 2.3.3.

5.2.3 During shafting calculation or actual measurement, if the allowable value of the rated speed is found to exceed that specified in the Rules or by the manufacturer, the actual τ_H may be used in the fatigue acceptability factor Q, and the actual value of the additional bending stress caused in axial vibration may be used. Where $Q \geq 1.15$ is still complied with, it is safe to the crankshaft. However, the related calculation data are to be submitted for examination.

5.3 Longitudinal vibration

5.3.1 Propulsion shafting of two-stroke diesel engines is to be subject to longitudinal vibration calculation, while four-stroke diesel engines will not cause longitudinal vibration of shafting. It may be found from 2.5 of this Appendix that additional alternating bending stress σ_{ax} at fillet caused by axial vibration equals to 20 MPa, and additional alternating bending stress caused by shafting misalignment is 10 MPa. Therefore, the diesel engine manufacturers are to determine the allowable amplitude of longitudinal vibration of the crankshaft free end in accordance with 20 MPa additional axial stress.

5.3.2 Diesel engine manufacturers may also provide the allowable amplitude of longitudinal vibration in accordance with the determined crankshaft dimensions and technology parameters on the basis of $Q \geq 1.15$, and submit related calculations for examination.

5.3.3 Under special conditions, if the amplitude of the longitudinal vibration at rated speed during actual measurement is found to exceed the value specified in the Rules or by the manufacturers, the actual σ_{ax} and τ_H may be used in the acceptability factor Q. Where $Q \geq 1.15$ is still complied with, it is safe to the crankshaft.

5.4 Alignment

5.4.1 After the diesel engine is connected with shafting, the bending moment and shearing force at the crankshaft ends due to shafting alignment causes additional bending stress upon crankpins. It is generally to be measured by means of controlling the difference of crank span.

5.4.2 For propulsion shafting of diesel engines needing to be aligned as specified in the Rules, reasonable alignment calculation and installation technology are to be submitted. Diesel engine manufacturers also specify the bending moment and shearing force in hot state and cold state on crankshaft of diesel engine.

During reasonable shafting alignment, if the bending moment and shearing force provided by the diesel engine manufacturers are not complied with but the crankshaft span difference still complies with the requirements, it is also acceptable. This is because the bending moment applied to the crankshaft end is shown in the form of the changing of the span difference.

5.5 Span difference

5.5.1 Additional bending stress σ_{add} given in 2.5 of this Appendix is actually the combination of additional stress σ_{ax} caused by axial vibration of shafting and additional compulsory repair bending stress σ_{aa}. Therefore, diesel engine manufacturers are to provide the span difference of the compulsory repair crankshafts in accordance with the σ_{aa} value adopted in the calculation of acceptability factor Q for actual use.

5.5.2 For two-stroke diesel engines, if there is no axial vibration of shafting or bending stress σ_{ax} caused by axial vibration < 20 MPa, or the margin of acceptability factor Q is greater, the compulsory repair span difference may be deduced on the basis of $Q \geq 1.15$. However, the related calculations are to be submitted for examination.

5.5.3 Where the span difference of the crankshafts of the ship in service exceeds the normal value or design value, the actual values τ_H, σ_{ax} and σ_{aa} may be used in Q. Where $Q \geq 1.15$ is complied with, it is safe to the crankshaft.

Annex I Guidance for Evaluation of Fatigue Tests of Crankshafts

4.2 Resonance tester
4.3 Use of results and crankshaft acceptability 5

Use of existing results for similar crankshafts

1 Introduction

Fatigue testing can be divided into two main groups: testing of small specimens and full-size crank throws. Testing can be made using the staircase method or a modified version thereof which is presented in this document. Other statistical evaluation methods may also be applied.

1.1 *Small specimen testing*

For crankshafts without any fillet surface treatment, the fatigue strength can be determined by testing small specimens taken from a full-size crank throw. When other areas in the vicinity of the fillets are surface treated introducing residual stresses in the fillets, this approach cannot be applied.

One advantage of this approach is the rather high number of specimens which can be then manufactured. Another advantage is that the tests can be made with different stress ratios (R-ratios) and/or different modes e.g. axial, bending and torsion, with or without a notch. This is required for evaluation of the material data to be used with critical plane criteria.

1.2 *Full-size crank throw testing*

For crankshafts with surface treatment the fatigue strength can only be determined through testing of full size crank throws. For cost reasons, this usually means a low number of crank throws. The load can be applied by hydraulic actuators in a 3- or 4- point bending arrangement, or by an exciter in a resonance test rig. The latter is frequently used, although it usually limits the stress ratio to $R = -1$.

2 Evaluation of test results

2.1 Principles

Prior to fatigue testing the crankshaft must be tested as required by quality control procedures, e.g. for chemical composition, mechanical properties, surface hardness, hardness depth and extension, fillet surface finish, etc.

The test samples are to be prepared so as to represent the “lower end” of the acceptance range e.g. for induction hardened crankshafts this means the lower range of acceptable hardness depth, the shortest extension through a fillet, etc. Otherwise the mean value test results are to be corrected with a confidence interval: a 90% confidence interval may be used both for the sample mean and the standard deviation.

The test results, when applied in check of crankshaft fatigue strength, are to be evaluated to represent the mean fatigue strength, with or without taking into consideration the 90% confidence interval as mentioned above. The standard deviation is to be considered by taking the 90% confidence into account. Subsequently the result to be used as the fatigue strength is then the mean fatigue strength minus one standard deviation.

If the evaluation aims to find a relationship between (static) mechanical properties and the fatigue strength, the relation must be based on the real (measured) mechanical properties, not on the specified minimum properties.

The calculation technique presented in 2.4 of this Annex was developed for the original staircase method. However, since there is no similar method dedicated to the modified staircase method the same is applied for both.

2.2 *Staircase method*

In the original staircase method, the first specimen is subjected to a stress corresponding to the expected average fatigue strength. If the specimen survives 10^7 cycles, it is discarded and the next specimen is subjected to a stress that is one increment above the previous, i.e. a survivor is always followed by the next using a stress one increment above the previous. The increment is to be selected to correspond to the expected level of the standard deviation.

When a specimen fails prior to reaching 10^7 cycles, the obtained number of cycles is noted and the next specimen is subjected to a stress that is one increment below the previous. With this approach, the sum of failures and run-outs is equal to the number of specimens.

This original staircase method is only suitable when a high number of specimens are available. Through simulations it has been found that the use of about 25 specimens in a staircase test leads to a sufficient accuracy in the result.

2.3 *Modified staircase method*

When a limited number of specimens are available, it is advisable to apply the modified staircase method. Here the first specimen is subjected to a stress level that is most likely well below the average fatigue strength. When this specimen has survived 10^7 cycles, this same specimen is subjected to a stress level one increment above the previous. The increment is to be selected to correspond to the expected level of the standard deviation.

This is continued with the same specimen until failure. Then the number of cycles is recorded and the next specimen is subjected to a stress that is at least 2 increments below the level where the previous specimen failed.

With this approach, the number of failures usually equals the number of specimens. The number of

run-outs, counted as the highest level where 10^7 cycles were reached, also equals the number of specimens. The acquired result of a modified staircase method is to be used with care, since some results available indicate that testing a run-out on a higher test level, especially at high mean stresses, tends to increase the fatigue limit. However, this "training effect" is less pronounced for high strength steels (e.g. UTS > 800 MPa).

If the confidence calculation is desired or necessary, the minimum number of test specimens is 3.

2.4 *Calculation of sample mean and standard deviation*

A hypothetical example of tests for 5 crank throws is presented further in the subsequent text. When using the modified staircase method and the evaluation method of Dixon and Mood, the number of samples will be 10, meaning 5 run-outs and 5 failures, i.e.:

Number of samples, n=10

Furthermore, the method distinguishes between:

(1) *Less frequent event is failures C=1*

(2) *Less frequent event is run-outs C=2*

The method uses only the less frequent occurrence in the test results, i.e. if there are more failures than run-outs, then the number of run-outs is used, and vice versa.

In the modified staircase method, the number of run-outs and failures are usually equal. However, the testing can be unsuccessful, e.g. the number of run-outs can be less than the number of failures if a specimen with 2 increments below the previous failure level goes directly to failure. On the other hand, if this unexpected premature failure occurs after a rather high number of cycles, it is possible to define the level below this as a run-out.

Dixon and Mood's approach, derived from the maximum likelihood theory, which also may be applied here, especially on tests with few samples, presented some simple approximate equations for calculating the sample mean and the standard deviation from the outcome of the staircase test.

The sample mean can be calculated as follows:

$$\bar{S}_a = S_{a0} + d \cdot \left(\frac{A}{F} - \frac{1}{2} \right) \quad \text{when } C=1$$

$$\bar{S}_a = S_{a0} + d \cdot \left(\frac{A}{F} + \frac{1}{2} \right) \quad \text{when } C=2$$

The standard deviation can be found by:

$$s = 1.62 \cdot d \cdot \left(\frac{F \cdot B - A^2}{F^2} + 0.029 \right)$$

where:

S_{a0} is the lowest stress level for the less frequent occurrence;

d is the stress increment;

$$F = \sum f_i ;$$

$$A = \sum i \cdot f_i ;$$

$$B = \sum i^2 \cdot f_i ;$$

i is the stress level numbering;

f_i is the number of samples at stress level i;

The formula for the standard deviation is an approximation and can be used when:

(1) $\frac{B \cdot F - A^2}{F^2} > 0.3$;

(2) $0.5 \cdot s < d < 1.5 \cdot s$.

If any of these two conditions are not fulfilled, a new staircase test is to be considered or the standard deviation is to be taken quite large in order to be on the safe side.

If increment d is greatly higher than the standard deviation s, the procedure leads to a lower standard deviation and a slightly higher sample mean, both compared to values calculated when the difference between the increment and the standard deviation is relatively small.

Respectively, if increment d is much less than the standard deviation s, the procedure leads to a higher standard deviation and a slightly lower sample mean.

2.5 *Confidence interval for mean fatigue limit*

If the staircase fatigue test is repeated, the sample mean and the standard deviation will most likely be different from the previous test. Therefore, it is necessary to assure with a given confidence that the repeated test values will be above the chosen fatigue limit by using a confidence interval for the sample mean.
The confidence interval for the sample mean value with unknown variance is known to be distributed according to the *t*-distribution (also called *student's t-distribution*) which is a distribution symmetric around the average.
The confidence level normally used for the sample mean is 90%, meaning that 90% of sample means from repeated tests will be above the value calculated with the chosen confidence level. Figure I-2.1 shows the *t*-value for (1 - α)·100% confidence interval for the sample mean.

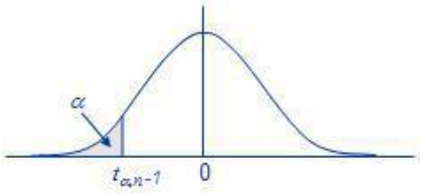

Figure I-2.1 Student's t-distribution

If S_a is the empirical mean and *s* is the empirical standard deviation over a series of *n* samples, in which the variable values are normally distributed with an unknown sample mean and unknown variance, the (1 - α)·100% confidence interval for the mean is:

$$P\left(S_a - t_{\alpha,n-1} \cdot \frac{s}{\sqrt{n}} < S_{aX\%}\right) = 1 - \alpha$$

The resulting confidence interval is symmetric around the empirical mean of the sample values, and the lower endpoint can be found as:

$$S_{aX\%} = S_a - t_{\alpha,n-1} \cdot \frac{s}{\sqrt{n}}$$

which is the mean fatigue limit (population value) to be used to obtain the reduced fatigue limit where the limits for the probability of failure are taken into consideration.

2.6 *Confidence interval for standard deviation*

The confidence interval for the variance of a normal random variable is known to possess a chi-square distribution with *n* - 1 degrees of freedom.
The confidence level on the standard deviation is used to ensure that the standard deviations for repeated tests are below an upper limit obtained from the fatigue test standard deviation with a confidence level. Figure I-2.2 shows the chi-square for (1 - α)·100% confidence interval for the variance.

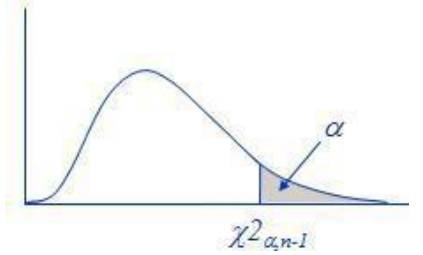

Figure I-2.2 Chi-square distribution

An assumed fatigue test value from *n* samples is a normal random variable with a variance of σ^2 and has an empirical variance s^2. Then a (1 - α)·100% confidence interval for the variance is:

$$P\left(\frac{(n-1)s^2}{\sigma^2} < x^2_{\alpha,n-1}\right) = 1 - \alpha$$

A (1 - α)·100% confidence interval for the standard deviation is obtained as follows:

$$S_{x\%} = \sqrt{\frac{n-1}{x^2_{\alpha,n-1}}} \cdot s$$

This standard deviation (population value) is to be used to obtain the fatigue limit, where the limits for the probability of failure are taken into consideration.

3 Small specimen testing

In this connection, a small specimen is considered to be one of the specimens taken from a crank throw. Since the specimens are to be representative for the fillet fatigue strength, they are to be taken out close to the fillets, as shown in Figure I-3.1.

It is to be made certain that the principal stress direction in the specimen testing is equivalent to the full-size crank throw. The verification is recommended to be done by utilizing the finite element method.

The (static) mechanical properties are to be determined as stipulated by the quality control procedures.

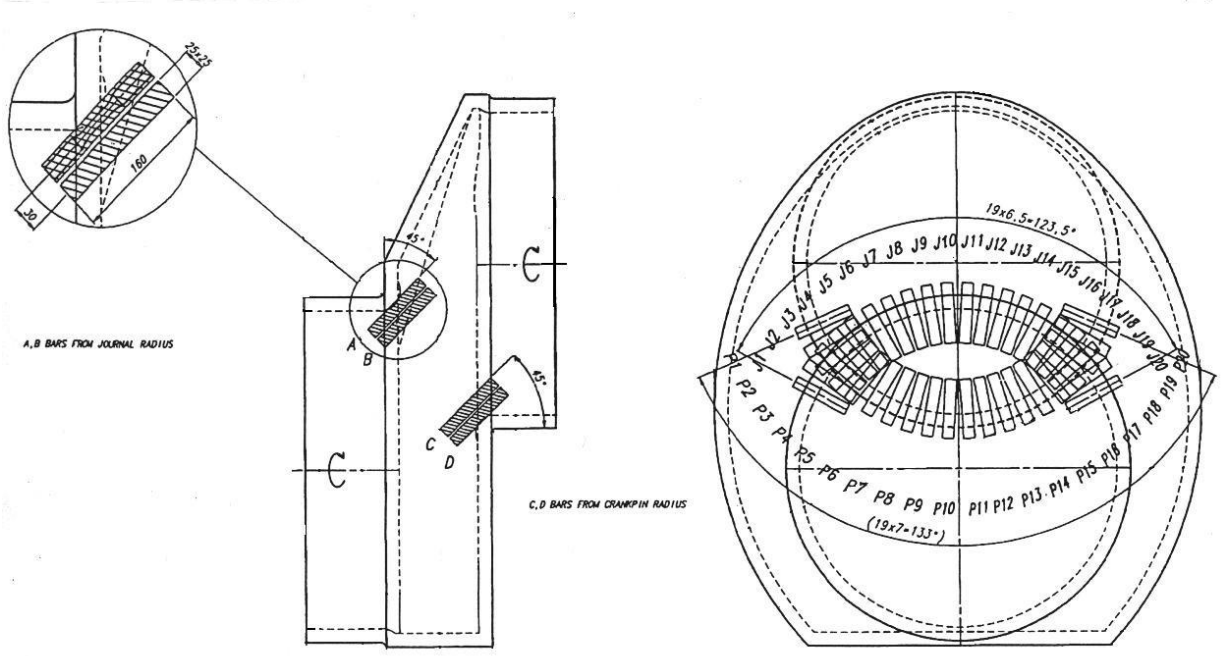

Figure I-3.1 Specimen locations in a crank throw

3.1 Determination of bending fatigue strength

It is advisable to use un-notched specimens in order to avoid uncertainties related to the stress gradient influence. Push-pull testing method (stress ratio $R = -1$) is preferred, but especially for the purpose of critical plane criteria other stress ratios and methods may be added.

In order to ensure principal stress direction in push-pull testing to represent the full-size crank throw principal stress direction and when no further information is available, the specimen is to be taken in 45 degrees angle as shown in Figure I-3.1.

(1) If the objective of the testing is to document the influence of high cleanliness, test samples taken from positions approximately 120 degrees in a circumferential direction may be used. See Figure I-3.1.

(2) If the objective of the testing is to document the influence of continuous grain flow (cgf) forging, the specimens are to be restricted to the vicinity of the crank plane.

3.2 *Determination of torsional fatigue strength*

(1) If the specimens are subjected to torsional testing, the selection of samples is to follow the same guidelines as for bending above. The stress gradient influence has to be considered in the evaluation.

(2) If the specimens are tested in push-pull and no further information is available, the samples are to be taken out at an angle of 45 degrees to the crank plane in order to ensure collinearity of the principal stress direction between the specimen and the full-size crank throw. When taking the specimen at a distance from the (crank) middle plane of the crankshaft along the fillet, this plane rotates around the pin centre point making it possible to re-sample the fracture direction due to torsion (the results are to be converted into the pertinent torsional values).

3.3 *Other test positions*

If the test purpose is to find fatigue properties and the crankshaft is forged in a manner likely to lead to cgf, the specimens may also be taken longitudinally from a prolonged shaft piece where specimens for mechanical testing are usually taken. The condition is that this prolonged shaft piece is heat treated as a part of the crankshaft and that the size is so as to result in a similar quenching rate as the crank throw.

When using test results from a prolonged shaft piece, it must be considered how well the grain flow in that shaft piece is representative for the crank fillets.

3.4 *Correlation of test results*

The fatigue strength achieved by specimen testing is to be converted to correspond to the full-size crankshaft fatigue strength with an appropriate method (size effect).
When using the bending fatigue properties from tests mentioned in this section, it is to be kept in mind that successful continuous grain flow (cgf) forging leading to elevated values compared to other (non cgf) forging, will normally not lead to a torsional fatigue strength improvement of the same magnitude.
In such cases it is advised to either carry out also torsional testing or to make a conservative assessment of the torsional fatigue strength, e.g. by using no credit for cgf. This approach is applicable when using the Gough Pollard criterion. However, this approach is not recognized when using the von Mises or a multi-axial criterion such as Findley.
If the found ratio between bending and torsion fatigue differs significantly from $\sqrt{3}$, one is to consider replacing the use of the von Mises criterion with the Gough Pollard criterion. Also, if critical plane criteria are used, it must be kept in mind that cgf makes the material inhomogeneous in terms of fatigue strength, meaning that the material parameters differ with the directions of the planes.
Any addition of influence factors must be made with caution. If for example a certain addition for clean steel is documented, it may not necessarily be fully combined with a *K*-factor for cgf. Direct testing of samples from a clean and cgf forged crank is preferred.

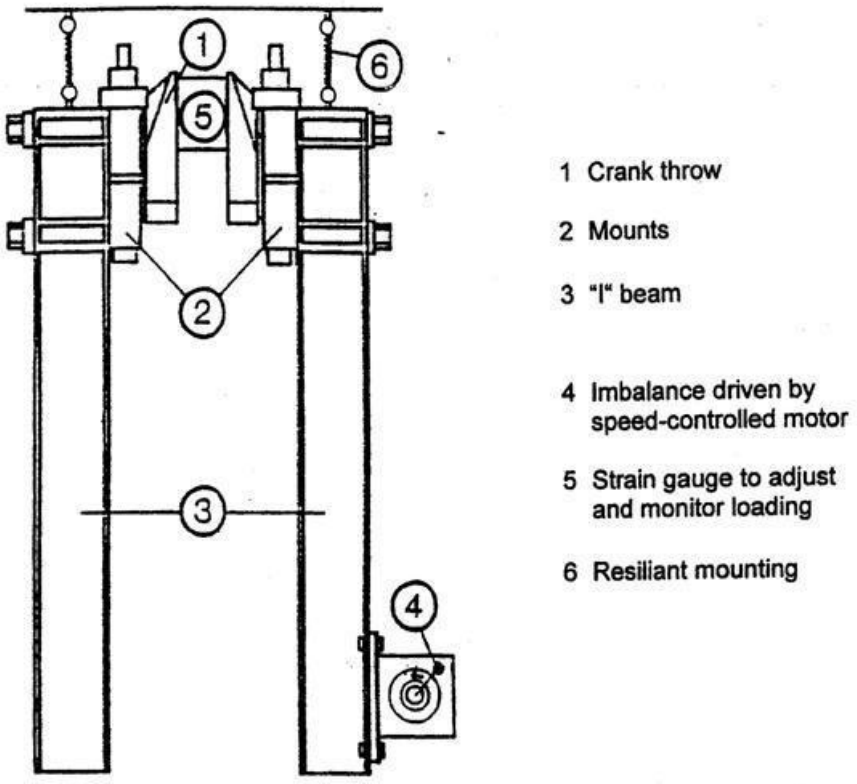
4 Full size testing

4.1 Hydraulic pulsation

A hydraulic test rig can be arranged for testing a crankshaft in 3-point or 4-point bending as well as in torsion. This allows for testing with any *R*-ratio.
Although the applied load is to be verified by strain gauge measurements on plain shaft sections for the initiation of the test, it is not necessarily used during the test for controlling load. It is also pertinent to check fillet stresses with strain gauge chains.
Furthermore, it is important that the test rig provides boundary conditions as defined in 2.4.5(3)①~③ of this Appendix.
The (static) mechanical properties are to be determined as stipulated by the quality control procedures.

4.2 *Resonance tester*

A rig for bending fatigue normally works with an *R*-ratio of -1. Due to operation close to resonance, the energy consumption is moderate. Moreover, the frequency is usually relatively high, meaning that 10^7 cycles can be reached within some days. Figure I-4.1 shows a layout of the testing arrangement.
The applied load is to be verified by strain gauge measurements on plain shaft sections. It is also pertinent to check fillet stresses with strain gauge chains.



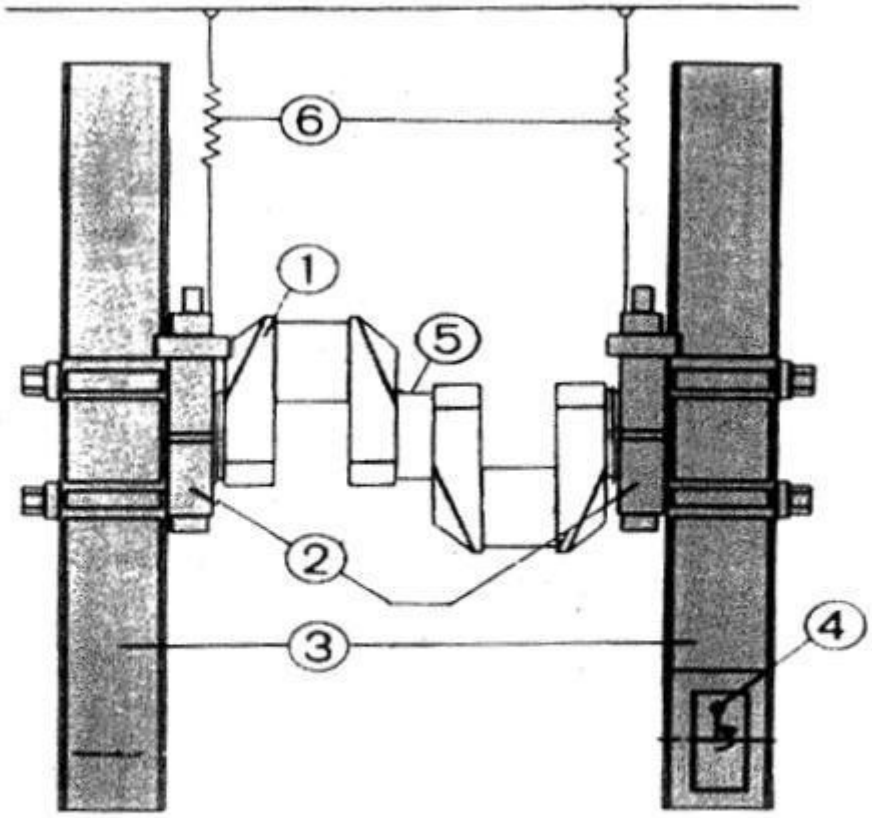


Figure I-4.1 An example of testing arrangement of the resonance tester for bending loading

Clamping around the journals must be arranged in a way that prevents severe fretting which could lead to a failure under the edges of the clamps. If some distance between the clamps and the journal fillets is provided, the loading is consistent with 4-point bending and thus representative for the journal fillets also.
In an engine, the crankpin fillets normally operate with an *R*-ratio slightly above -1 and the journal fillets slightly below -1. If found necessary, it is possible to introduce a mean load (deviate from $R = -1$) by means of a spring preload.
A rig for torsion fatigue can also be arranged as shown in Figure I-4.2. When a crank throw is subjected to torsion, the twist of the crankpin makes the journals move sideways. If one single crank throw is tested in a torsion resonance test rig, the journals with their clamped-on weights will vibrate heavily sideways.
This sideway movement of the clamped-on weights can be reduced by having two crank throws, especially if the cranks are almost in the same direction. However, the journal in the middle will move more.

① crankthrow
② clamping jaw
③ I-profiled beams
④ motor-driven eccentric weight
⑤ strain gage
⑥ elastic suspension

Figure I-4.2 An example of testing arrangement of the resonance tester for torsion loading with double crank throw section

Since sideway movements can cause some bending stresses, the plain portions of the crankpins are also to be provided with strain gauges arranged to measure any possible bending that could have an influence on the test results.
Similarly, to the bending case the applied load is to be verified by strain gauge measurements on plain shaft sections. It is also pertinent to check fillet stresses with strain gauge chains as well.

4.3 *Use of results and crankshaft acceptability*

In order to combine tested bending and torsion fatigue strength results in calculation of crankshaft acceptability, see 2.8 of this Appendix, the Gough-Pollard approach and the maximum principal equivalent stress formulation can be applied for the following cases:

At the crankpin fillet:

$$Q = \left(\sqrt{\left(\frac{\sigma_{BH} + \sigma_{add}}{\sigma_{DWCT}} \right)^2 + \left(\frac{\tau_H}{\tau_{DWCT}} \right)^2} \right)^{-1}$$

where:

σ_{DWCT}— fatigue strength by bending testing;

τ_{DWCT}— fatigue strength by torsion testing.

For other parameters see this Appendix.

Related to crankpin oil bore:

$$Q = \frac{\sigma_{DWOT}}{\sigma_v}$$

where:

σ_{DWOT}—fatigue strength by means of largest principal stress from torsion testing;

$$\sigma_v = \pm \frac{1}{3} \sigma_{BO} \left[1 + 2 \sqrt{1 + \frac{9}{4} \left(\frac{\sigma_{TO}}{\sigma_{BO}} \right)^2} \right], \quad \text{MPa}$$

At the journal fillet:

$$Q = \left(\sqrt{\left(\frac{\sigma_{BG} + \sigma_{add}}{\sigma_{DWJT}} \right)^2 + \left(\frac{\tau_G}{\tau_{DWJT}} \right)^2} \right)^{-1}$$

where:

σ_{DWJT}— fatigue strength by bending testing;

τ_{DWJT}— fatigue strength by torsion testing.

For other parameters see this Appendix.

In case increase in fatigue strength due to the surface treatment is considered to be similar between the above cases, it is sufficient to test only the most critical location according to the calculation where the surface treatment had not been taken into account.

5 *Use of existing results for similar crankshafts*

For fillets or oil bores without surface treatment, the fatigue properties found by testing may be used for similar crankshaft designs providing:

(1) *Material:*

- Similar material type;
- Cleanliness on the same or better level;
- The same mechanical properties can be granted (size versus hardenability).

(2) *Geometry:*

- Difference in the size effect of stress gradient is insignificant or it is considered;
- Principal stress direction is equivalent. See Part 3 of this Annex.

(3) *Manufacturing:*

- Similar manufacturing process.

Induction hardened or gas nitrited crankshafts will suffer fatigue either at the surface or at the transition to the core. The surface fatigue strength as determined by fatigue tests of full size cranks, may be used on an equal or similar design as the tested crankshaft when the fatigue initiation occurred at the surface. With the similar design, it is meant that a similar material type and surface hardness are used and the fillet radius and hardening depth are within approximately ± 30 % of the tested crankshaft.

Fatigue initiation in the transition zone can be either subsurface, i.e. below the hard layer, or at the surface where the hardening ends. The fatigue strength at the transition to the core can be determined by fatigue tests as described above, provided that the fatigue initiation occurred at the transition to the core. Tests made with the core material only will not be representative since the tension residual stresses at the transition are lacking.

It has to be noted also what some recent research has shown: The fatigue limit can decrease in the very high cycle domain with subsurface crack initiation due to trapped hydrogen that accumulates through diffusion around some internal defect functioning as an initiation point.
In these cases, it would be appropriate to reduce the fatigue limit by some percent per decade of cycles beyond 10^7. Based on a publication by Yukitaka Murakami "Metal Fatigue: Effects of Small Defects and Non-metallic Inclusions" the reduction is suggested to be 5 % per decade especially when the hydrogen content is considered to be high.

1 *Introduction*

This Annex deals with surface treated fillets and oil bore outlets. The various treatments are explained and some empirical formulae are given for calculation purposes. Conservative empiricism has been applied intentionally, in order to be on the safe side from a calculation standpoint.

Please note that measurements or more specific knowledge are to be used if available. However, in the case of a wide scatter (e.g. for residual stresses) the values are to be chosen from the end of the range that would be on the safe side for calculation purposes.

2 *Definition of surface treatment*

Surface treatment is a term covering treatments such as thermal, chemical or mechanical operations, leading to inhomogeneous material properties - such as hardness, chemistry or residual stresses – from the surface to the core.

2.1 Surface treatment methods

Table 2.1 covers possible treatment methods and how they influence the properties that are decisive for the fatigue strength.

Surface treatment methods and the characteristics they affect *Table 2.1*

Treatment method	**Affecting**
Induction hardening	Hardness and residual stresses
Nitriding	Chemistry, hardness and residual stresses
Case hardening	Chemistry, hardness and residual stresses
Die quenching (no temper)	hardness and residual stresses
Cold rolling	residual stresses
Stroke peening	residual stresses
Shot peening	residual stresses
Laser peening	residual stresses
Ball coining	residual stresses

It is important to note that since only induction hardening, nitriding, cold rolling and stroke peening are considered relevant for marine engines, other methods as well as combination of two or more of the above are not dealt with in this Annex. In addition, die quenching can be considered in the same way as induction hardening.

3 *Calculation principles*

The basic principle is that the alternating working stresses are to be below the local fatigue strength (including the effect of surface treatment) wherein non-propagating cracks may occur, see also section 6.1 of this Annex for details. This is then divided by a certain safety factor. This applies through the entire fillet or oil bore contour as well as below the surface to a depth below the treatment- i.e. to cover the depth all the way to the core.

Consideration of the local fatigue strength is to include the influence of the local hardness, residual stress and mean working stress. The influence of the “giga-cycle effect”, especially for initiation of subsurface cracks, is to be covered by the choice of safety margin.

It is of vital importance that the extension of hardening/peening in an area with concentrated stresses be duly considered. Any transition where the hardening/peening is ended is likely to have considerable tensile residual stresses. This forms a “weak spot” and is important if it coincides with an area of high stresses.

Alternating and mean working stresses must be known for the entire area of the stress concentration as well as to a depth of about 1.2 times the depth of the treatment. Figure II-3.1 indicates this principle in the case of induction hardening. The base axis is either the depth (perpendicular to the surface) or along the fillet contour. The acceptability criterion is to be applied stepwise from the surface to the core as well as from the point of maximum stress concentration along the fillet surface contour to the web.

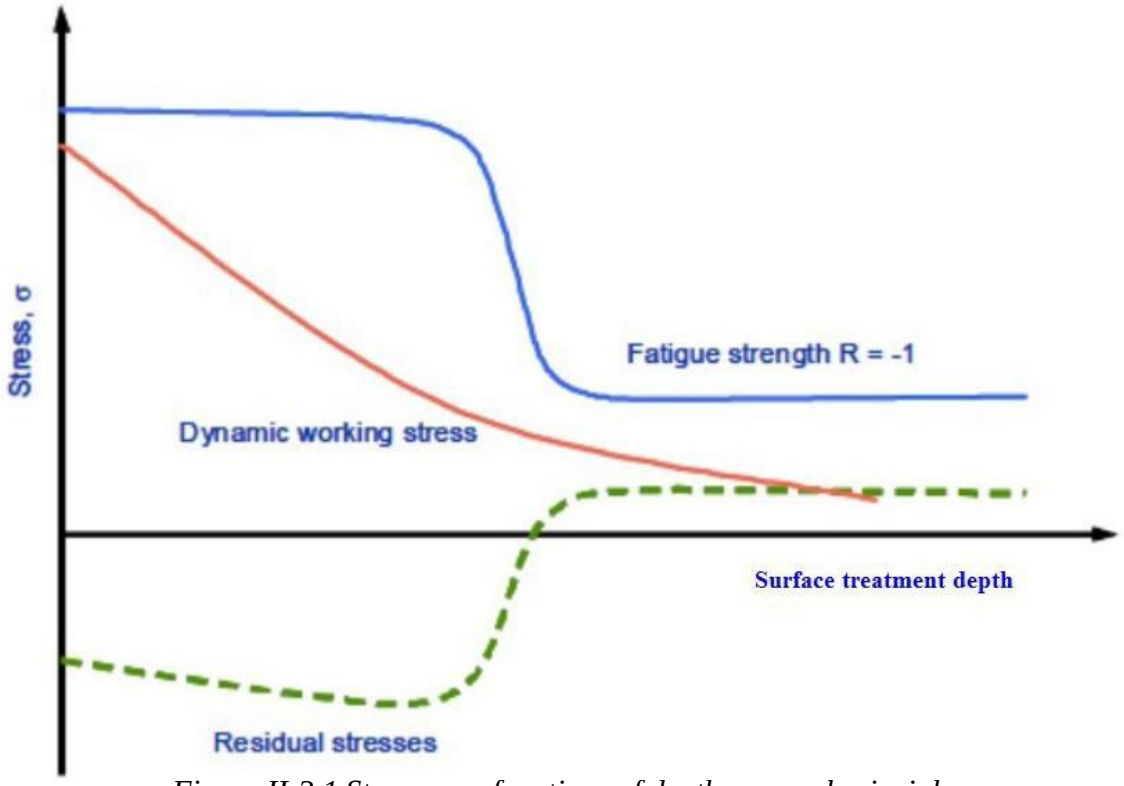

Figure II-3.1 Stresses as functions of depth, general principles

3.1 Evaluation of local fillet stresses

It is necessary to have knowledge of the stresses along the fillet contour as well as in the subsurface to a depth somewhat beyond the hardened layer. Normally this will be found via FEA as described in 2.4.5 of this Appendix. However, the element size in the subsurface range will have to be the same size as at the surface. For crankpin hardening only the small element size will have to be continued along the surface to the hard layer.

If no FEA is available, a simplified approach may be used. This can be based on the empirically determined stress concentration factors (SCFs), as in 2.4 of this Appendix if within its validity range, and a relative stress gradient inversely proportional to the fillet radius.

Bending and torsional stresses must be addressed separately. The combination of these is addressed by the acceptability criterion.

The subsurface transition-zone stresses, with the minimum hardening depth, can be determined by means of local stress concentration factors along an axis perpendicular to the fillet surface. These functions $\alpha_{B\text{-}local}$ and $\alpha_{T\text{-}local}$ have different shapes due to the different stress gradients.

The SCFs α_B and α_T are valid at the surface. The local $\alpha_{B\text{-}local}$ and $\alpha_{T\text{-}local}$ drop with increasing depth. The relative stress gradients at the surface depend on the kind of stress raiser, but for crankpin fillets they can be simplified to $2/R_H$ in bending and $1/R_H$ in torsion. The journal fillets are handled analogously by using R_G and D_G. The nominal stresses are assumed to be linear from the surface to a midpoint in the web between the crankpin fillet and the journal fillet for bending and to the crankpin or journal centre for torsion.

The local SCFs for crankpin fillet are then functions of depth *t* according to Equation 3.1 as shown in Figure II-3.2 for bending and respectively for torsion in Equation 3.2 and Figure II-3.3. The corresponding bending SCF and torsion SCF for the journal fillet can be found by replacing R_H with R_G and D_P with D_G.

$$\alpha_{B-local} = (\alpha_B - 1) \cdot e_1^{\frac{-2t}{R_H}} + 1 - \left(\frac{2 \cdot t}{\sqrt{W^2 + e^2}} \right)^{\frac{0.6}{\sqrt{\alpha_B}}} \qquad (3.1)$$

$$\alpha_{T-local} = (\alpha_T - 1) \cdot e_1^{\frac{-t}{R_H}} + 1 - \left(\frac{2 \cdot t}{D_p} \right)^{\frac{1}{\sqrt{\alpha_T}}} \qquad (3.2)$$

where: e_1 is natural constant, and other symbols are defined in 2.4.1 in this Appendix.

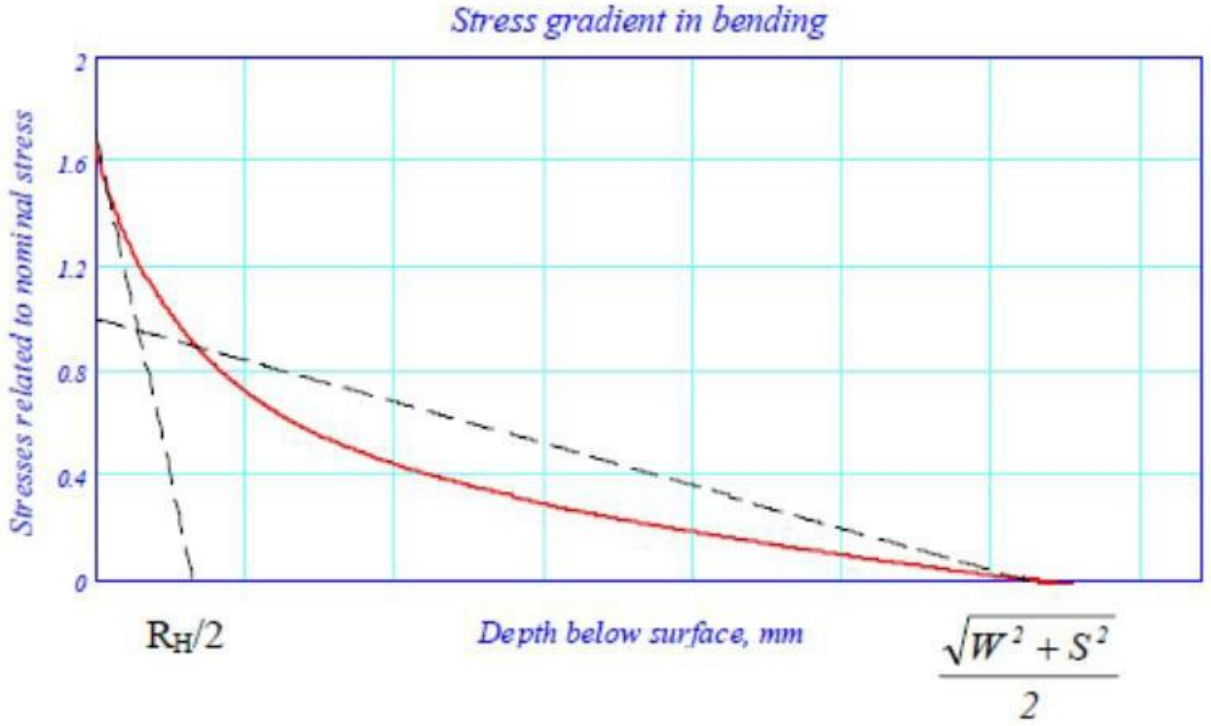

Figure II-3.2 Bending SCF in the crankpin fillet as a function of depth

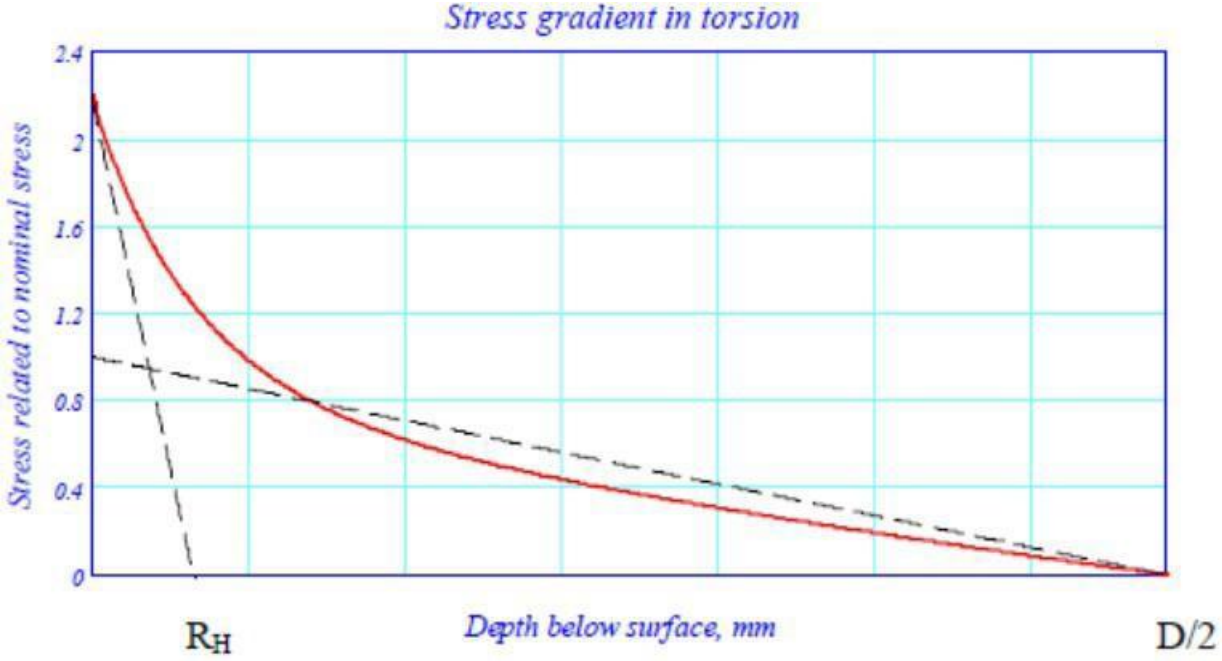

Figure II-3.3 Torsional SCF in the crankpin fillet as a function of depth

If the pin is hardened only and the end of the hardened zone is closer to the fillet than three times the maximum hardness depth, FEA is to be used to determine the actual stresses in the transition zone.

3.2 Evaluation of oil bore stresses

Stresses in the oil bores can be determined also by FEA. The element size is to be less than 1/8 of the oil bore diameter D_o and the element mesh quality criteria is to be followed as prescribed in Annex III. The fine element mesh is to continue well beyond a radial depth corresponding to the hardening depth.

The loads to be applied in the FEA are the torque – see Annex III item 3.1 – and the bending moment, with four-point bending as in Annex III item 3.2 of this Appendix.

If no FEA is available, a simplified approach may be used. This can be based on the empirically determined SCF from 2.4 of this Appendix if within its applicability range. Bending and torsional stresses at the point of peak stresses are combined as in 2.6 of this Appendix.

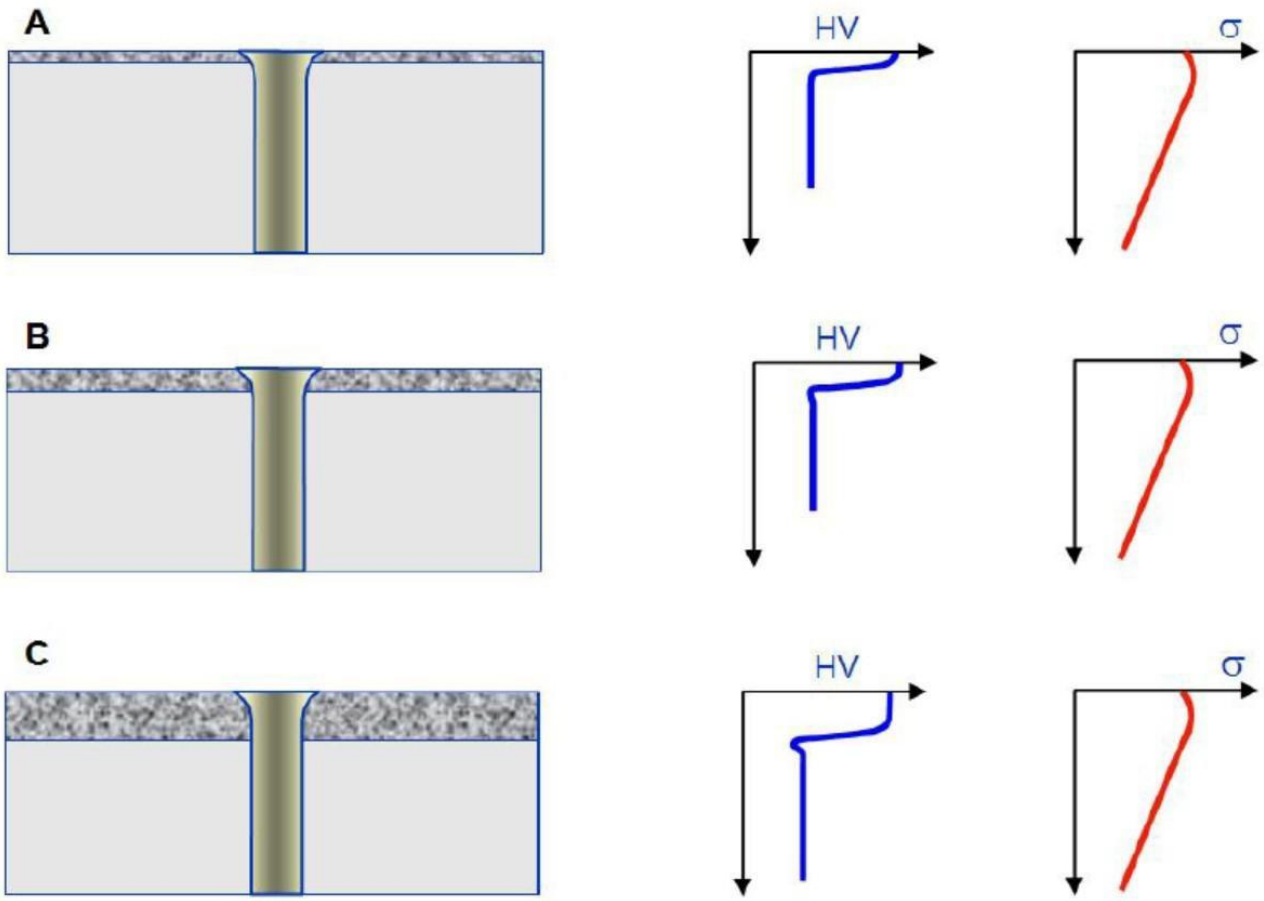

Figure II-3.4 Stresses and hardness in induction hardened oil holes

Figure II-3.4 indicates a local drop of the hardness in the transition zone between a hard and soft material. Whether this drop occurs depends also on the tempering temperature after quenching in the QT process.
The peak stress in the bore occurs at the end of the edge rounding. Within this zone the stress drops almost linearly to the centre of the pin. As can be seen from Figure II-3.4, for shallow (A) and intermediate (B) hardening, the transition point practically coincides with the point of maximal stresses. For deep hardening the transition point comes outside of the point of peak stress and the local stress can be assessed as a portion (1-2*tH/D*) of the peak stresses where *tH* is the hardening depth.
The subsurface transition-zone stresses (using the minimum hardening depth) can be determined by means of local stress concentration factors along an axis perpendicular to the oil bore surface. These functions $\gamma_{B-local}$ and $\gamma_{T-local}$ have different shapes, because of the different stress gradients.
The stress concentration factors γ_B and γ_T are valid at the surface. The local SCFs $\gamma_{B-local}$ and $\gamma_{T-local}$ drop with increasing depth. The relative stress gradients at the surface depend on the kind of stress raiser, but for crankpin oil bores they can be simplified to $4/D_o$ in bending and $2/D_o$ in torsion. The local SCFs are then functions of the depth *t*:

$$\gamma_{B-local} = (\gamma_B - 1) \cdot e^{\frac{-4 \cdot t}{D_o}} + 1 \qquad (3.3)$$

$$\gamma_{T-local} = (\gamma_T - 1) \cdot e^{\frac{-2 \cdot t}{D_o}} + 1 \qquad (3.4)$$

where: e_1 is natural constant, and other symbols are defined in 2.4.1 in this Appendix.

3.3 Acceptability criteria

Acceptance of crankshafts is based on fatigue considerations; the equivalent alternating stress and the fatigue strength ratio are compared to an acceptability factor of $Q \geq 1.15$ for oil bore outlets, crankpin fillets and journal fillets. This is to be extended to cover also surface treated areas independent of whether surface or transition zone is examined.

4 *Induction hardening*

Generally, the hardness specification is to specify the surface hardness range i.e. minimum and maximum values, the minimum and maximum extension in or through the fillet and also the minimum and maximum depth along the fillet contour. The referenced Vickers hardness is considered to be HV0.5-HV5.

The induction hardening depth is defined as the depth where the hardness is 80% of the minimum specified surface hardness.

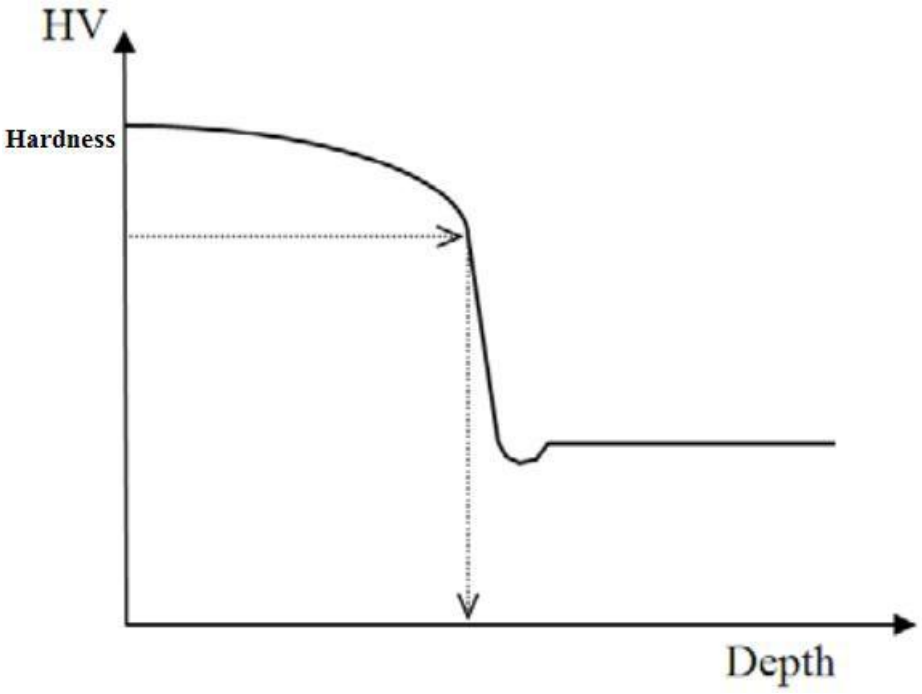

Figure II-4.1 Typical hardness as a function of depth

The arrows indicate the defined hardening depth. Note the indicated potential hardness drop at the transition to the core. This can be a weak point as local strength may be reduced and tensile residual stresses may occur.

In the case of crankpin or journal hardening only, the minimum distance to the fillet is to be specified due to the tensile stress at the heat-affected zone as shown in Figure II-4.2.

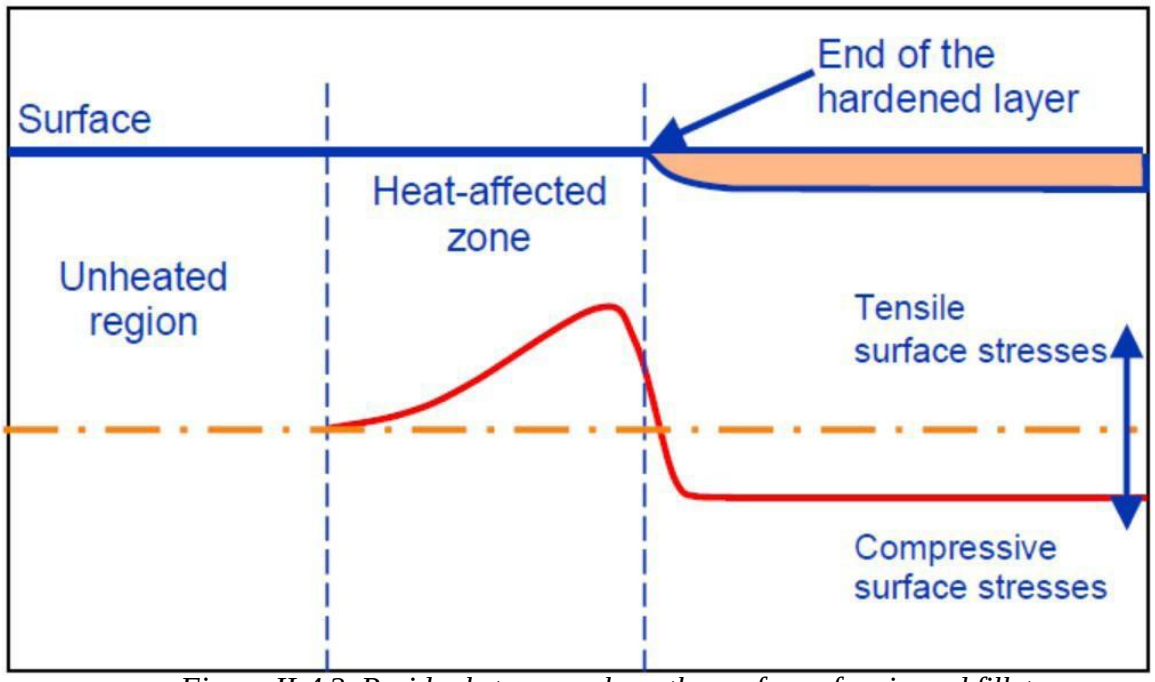

Figure II-4.2 Residual stresses along the surface of a pin and fillet

If the hardness-versus-depth profile and residual stresses are not known or specified, one may assume the following:
(1) The hardness profile consists of two layers (see Figure II-4.1):
- Constant hardness from the surface to the transition zone;
- Constant hardness from the transition zone to the core material;

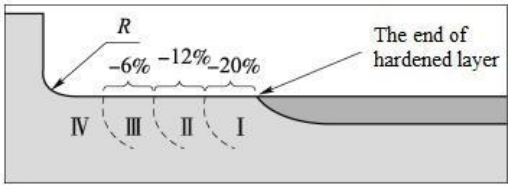
(2) Residual stresses in the hard zone of 200 MPa (compression);
(3) Transition-zone hardness as 90% of the core hardness unless the local hardness drop is avoided;
(4) Transition-zone maximum residual stresses (von Mises) of 300 MPa tension.
If the crankpin or journal hardening ends close to the fillet, the influence of tensile residual stresses has to be considered. If the minimum distance between the end of the hardening and the beginning of the fillet is more than 3 times the maximum hardening depth, the influence may be disregarded.

4.1 Local fatigue strength

Induction-hardened crankshafts will suffer fatigue either at the surface or at the transition to the core. The fatigue strengths, for both the surface and the transition zone, can be determined by fatigue testing of full size cranks as described in Annex I of this Appendix. In the case of a transition zone, the initiation of the fatigue can be either subsurface (i.e. below the hard layer) or at the surface where the hardening ends.
Tests made with the core material only will not be representative since the tensile residual stresses at the transition are lacking.
Alternatively, the surface fatigue strength can be determined empirically as follows where *HV* is the surface Vickers hardness. The Equation 4.1 provides a conservative value, with which the fatigue strength is assumed to include the influence of the residual stress. The resulting value is valid for a working stress ratio of R = -1:
It has to be noted also that the mean stress influence of induction-hardened steels may be significantly

$$\sigma_{Fsurface} = 400 + 0.5 \cdot (HV - 400) \quad \text{MPa} \quad (4.1)$$

higher than that for QT steels.
The fatigue strength in the transition zone, without taking into account any possible local hardness drop, is to be determined by the equation introduced in 2.7 of this Appendix.
For journal and respectively to crankpin fillet applies:



$$\sigma_{\text{Ftransition,cpin}} = \pm K \cdot \left(0.42 R_m + 39.3\right) \cdot \left[0.264 + 1.073 \text{Y}^{-0.2} + \frac{785 - R_m}{4900} + \frac{196}{R_m} \cdot \sqrt{\frac{1}{\text{X}}}\right] \quad (4.2)$$

where:

$Y = D_G$ and $X = R_G$ for journal fillet
$Y = D_p$ and $X = R_H$ for crankpin fillet
$Y = D_p$ and $X = D_o/2$ for oil bore outlet
The influence of the residual stress is not included in 4.2.
For the purpose of considering subsurface fatigue, below the hard layer, the disadvantage of tensile residual stresses has to be considered by subtracting 20% from the value determined above. This 20% is based on the mean stress influence of alloyed quenched and tempered steel having a residual tensile stress of 300 MPa.
When the residual stresses are known to be lower, also smaller value of subtraction is to be used. For low-strength steels the percentage chosen is to be higher.
For the purpose of considering surface fatigue near the end of the hardened zone – i.e. in the heat-affected zone shown in the Figure II-4.2 - the influence of the tensile residual stresses can be considered by subtracting a certain percentage, in accordance with Table 4.1, from the value determined by the above formula.

The influence of tensile residual stresses at a given distance from the end of the hardening towards the fillet

Table 4.1

Zone	Scope	Strength coefficient	Illustration of heat affected zones and strength coefficients
I II III IV	0-tH tH-2tH 2tH-3tH 3tH or more	0.8 0.88 0.94 1	

5 Nitriding

The hardness specification is to include the surface hardness range (min and max) and the minimum and maximum depth. Only gas nitriding is considered. The referenced Vickers hardness is considered to be HV0.5.

The depth of the hardening is defined in different ways in the various standards and the literature. The most practical method to use in this context is to define the nitriding depth tN as the depth to a hardness of 50 HV above the core hardness.

The hardening profile is to be specified all the way to the core. If this is not known, it may be determined empirically via the following formula:

$$HV(t) = HV_{core} + (HV_{surface} - HV_{core}) \cdot \left(\frac{50}{HV_{surface} - HV_{core}} \right)^{\left(\frac{t}{tN}\right)^2} \qquad (5.1)$$

where:

t = The local depth;

$HV(t)$ = Hardness at depth t;

HV_{core} = Core hardness (minimum);

$HV_{surface}$ = Surface hardness (minimum);

tN = Nitriding depth as defined above (minimum).

5.1 Local fatigue strength

It is important to note that in nitrided crankshaft cases, fatigue is found either at the surface or at the transition to the core. This means that the fatigue strength can be determined by tests as described in Annex I of this Appendix.

Alternatively, the surface fatigue strength (principal stress) can be determined empirically and conservatively as follows. This is valid for a surface hardness of 600 HV or greater:

$$\sigma_{Fsurface} = 450 \text{ MPa} \qquad (5.2)$$

Note that this fatigue strength is assumed to include the influence of the surface residual stress and applies for a working stress ratio of R = -1.

The fatigue strength in the transition zone can be determined by the equation introduced in 2.7 of this Appendix. For crankpin and respectively to journal applies:

$$\sigma_{Ftransition,cpin} = \pm K \cdot (0.42 R_m + 39.3) \cdot \left[0.264 + 1.073 \cdot Y^{-0.2} + \frac{785 - R_m}{4900} + \frac{196}{R_m} \cdot \sqrt{\frac{1}{X}} \right] \qquad (5.3)$$

where:

$Y = D_G$ and $X = R_G$ for journal fillet;

$Y = D_p$ and $X = R_H$ for crankpin fillet;

$Y = D_p$ and $X = D_0/2$ for oil bore outlet.

Note that this fatigue strength is not assumed to include the influence of the residual stresses.

In contrast to induction-hardening the nitrited components have no such distinct transition to the core, as indicated by Figure II-5.1. Although the compressive residual stresses at the surface are high, the balancing tensile stresses in the core are moderate because of the shallow depth. For the purpose of analysis of subsurface fatigue the disadvantage of tensile residual stresses in and below the transition zone may be even disregarded in view of this smooth contour of a nitriding hardness profile.

Although in principle the calculation is to be carried out along the entire hardness profile, it can be limited to a simplified approach of examining the surface and an artificial transition point. This artificial transition

point can be taken at the depth where the local hardness is approximately 20 HV above the core hardness. In such a case, the properties of the core material are to be used. This means that the stresses at the transition to the core can be found by using the local SCF formulae mentioned earlier when inserting t=1.2tN.

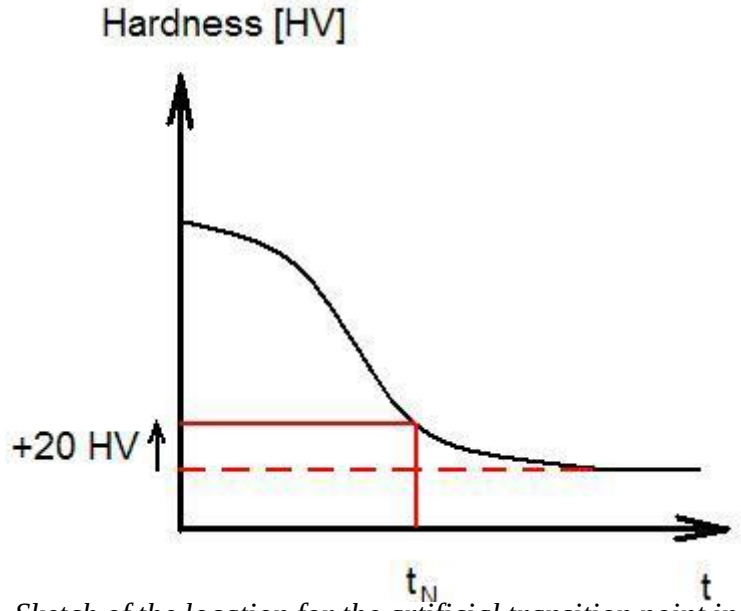


Figure II-5.1 Sketch of the location for the artificial transition point in the depth direction

6 Cold forming

The advantage of stroke peening or cold rolling of fillets is the compressive residual stresses introduced in the high-loaded area. Even though surface residual stresses can be determined by X-ray diffraction technique and subsurface residual stresses can be determined through neutron diffraction, the local fatigue strength is virtually non-assessable on that basis since suitable and reliable correlation formulae are hardly known.

Therefore, the fatigue strength has to be determined by fatigue testing; see also Annex I of this Appendix. Such testing is normally carried out as four-point bending, with a working stress ratio of R = -1. From these results, the bending fatigue strength - surface- or subsurface-initiated depending on the manner of failure-can be determined and expressed as the representative fatigue strength for applied bending in the fillet.

In comparison to bending, the torsion fatigue strength in the fillet may differ considerably from the ratio $\sqrt{3}$ (utilized by the von Mises criterion). The forming-affected depth that is sufficient to prevent subsurface fatigue in bending, may still allow subsurface fatigue in torsion. Another possible reason for the difference in bending and torsion could be the extension of the highly stressed area.

The results obtained in a full-size crank test can be applied for another crank size provided that the base material (alloyed Q+T) is of the similar type and that the forming is done so as to obtain the similar level of compressive residual stresses at the surface as well as through the depth. This means that both the extension and the depth of the cold forming must be proportional to the fillet radius.

6.1 Stroke peening by means of a ball

The fatigue strength obtained can be documented by means of full size crank tests or by empirical methods if applied on the safe side. If both bending and torsion fatigue strengths have been investigated and differ from the ratio $\sqrt{3}$, the von Mises criterion is to be excluded.

If only bending fatigue strength has been investigated, the torsional fatigue strength is to be assessed conservatively. If the bending fatigue strength is concluded to be x% above the fatigue strength of the non-peened material, the torsional fatigue strength is not to be assumed to be more than 2/3 of x% above that of the non-peened material.

As a result of the stroke peening process the maximum of the compressive residual stress is found in the subsurface area. Therefore, depending on the fatigue testing load and the stress gradient, it is possible to have higher working stresses at the surface in comparison to the local fatigue strength of the surface. This is illustrated in Figure II-6.1. Because of this phenomenon small cracks may appear during the fatigue testing, which will not be able to propagate in further load cycles and/or with further slight increases of the testing load because of the profile of the compressive residual stress. Put simply, the high compressive residual

stresses below the surface “arrest” small surface cracks.

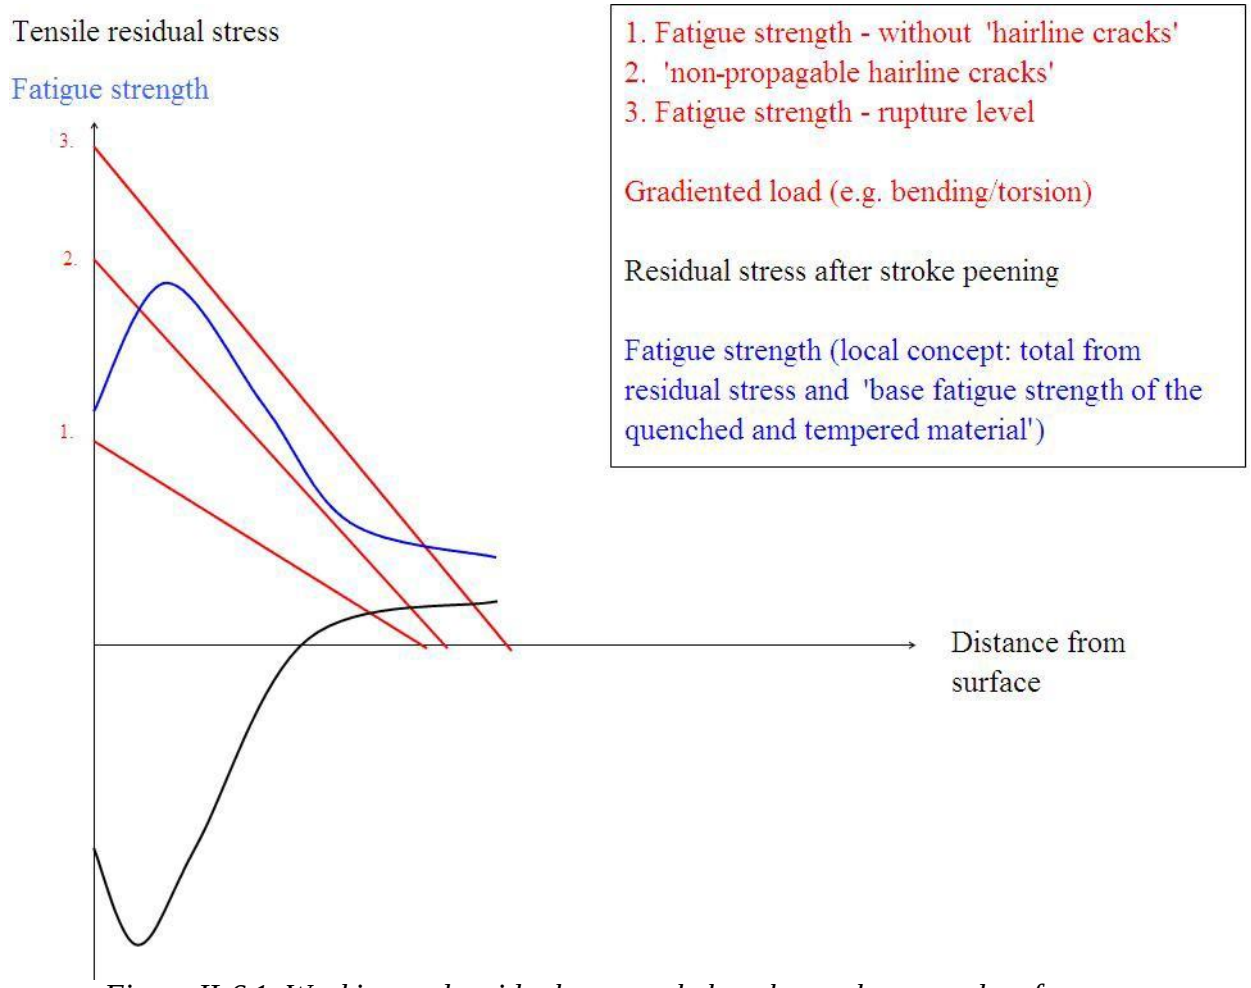

Figure II-6.1 Working and residual stresses below the stroke-peened surface

In fatigue testing with full-size crankshafts these small “hairline cracks” are not to be considered to be the failure crack. The crack that is technically the fatigue crack leading to failure, and that therefore shuts off the test-bench, is to be considered for determination of the failure load level. This also applies if induction-hardened fillets are stroke-peened.

In order to improve the fatigue strength of induction-hardened fillets it is possible to apply the stroke peening process in the crankshafts’ fillets after they have been induction-hardened and tempered to the required surface hardness. If this is done, it might be necessary to adapt the stroke peening force to the hardness of the surface layer and not to the tensile strength of the base material. The effect on the fatigue strength of induction hardening and stroke peening the fillets are to be determined by a full-size crankshaft test.

6.1.1 Use of existing results for similar crankshafts

The increase in fatigue strength, which is achieved by applying stroke peening, may be utilized in another similar crankshaft if all of the following criteria are fulfilled:

(1) Ball size relative to fillet radius within ±10% in comparison to the tested crankshaft;

(2) At least the same circumferential extension of the stroke peening;

(3) Angular extension of the fillet contour relative to fillet radius within ±15% in comparison to the tested crankshaft and located to cover the stress concentration during engine operation;

(4) Similar base material, e.g. alloyed quenched and tempered;

(5) Forward feed of ball of the same proportion of the radius;

(6) Force applied to ball proportional to base material hardness (if different);

(7) Force applied to ball proportional to square of ball radius.

6.2 Cold rolling

The fatigue strength can be obtained by means of full size crank tests or by empirical methods, if these are

applied so as to be on the safe side. If both, bending and torsion fatigue strengths have been investigated, and differ from the ratio $\sqrt{3}$, the von Mises criterion is to be excluded.

If only bending fatigue strength has been investigated, the torsional fatigue strength is to be assessed conservatively. If the bending fatigue strength is concluded to be x% above the fatigue strength of the non-rolled material, the torsional fatigue strength is not to be assumed to be more than 2/3 of x% above that of the non-rolled material.

6.2.1 Use of existing results for similar crankshafts

The increase in fatigue strength, which is achieved applying cold rolling, may be utilized in another similar crankshaft if all of the following criteria are fulfilled:

(1) At least the same circumferential extension of cold rolling;

(2) Angular extension of the fillet contour relative to fillet radius within ±15% in comparison to the tested crankshaft and located to cover the stress concentration during engine operation;

(3) Similar base material, e.g. alloyed quenched and tempered;

(4) Roller force to be calculated so as to achieve at least the same relative (to fillet radius) depth of treatment.

Annex III Guidance for Calculation of Stress Concentration Factors in the Oil Bore Outlets of crankshafts through utilisation of the Finite Element Method

Contents

1 General

2 Model requirements
2.1 Element mesh recommendations
2.2 Material
2.3 Element mesh quality criteria

3 Load cases and assessment of stress
3.1 Torsion
3.2 Bending

1 *General*

The objective of the analysis described in this Annex is to substitute the analytical calculation of the stress concentration factor (SCF) at the oil bore outlet with suitable finite element method (FEM) calculated figures. The former method specified in 2.4.4 of this Appendix is based on empirical formulae developed from strain gauge readings or photo-elasticity measurements of various round bars. Because use of these formulae beyond any of the validity ranges can lead to erroneous results in either direction, the FEM-based method is highly recommended.

The SCF calculated according to the rules set forth in this document is defined as the ratio of FEM-calculated stresses to nominal stresses calculated analytically. In use in connection with the present method in this Appendix, principal stresses are to be calculated.

The analysis is to be conducted as linear elastic FE analysis, and unit loads of appropriate magnitude are to be applied for all load cases.

It is advisable to check the element accuracy of the FE solver in use, e.g. by modelling a simple geometry and comparing the FEM-obtained stresses with the analytical solution.

A boundary element method (BEM) approach may be used instead of FEM.

2 *Model requirements*

The basic recommendations and assumptions for building of the FE-model are presented in 2.1 of this Annex. The final FE-model must meet one of the criteria in 2.3 of this Annex.

2.1 Element mesh recommendations

For the mesh quality criteria to be met, construction of the FE model for the evaluation of stress concentration factors according to the following recommendations is advised:

(1) The model consists of one complete crank, from the main bearing centre line to the opposite side's main bearing centre line.

(2) The following element types are used in the vicinity of the outlets: 10-node tetrahedral elements; 8-node hexahedral elements; 20-node hexahedral elements.

(3) The following mesh properties for the oil bore outlet are used:

- Maximum element size a = r / 4 through the entire outlet fillet as well as in the bore direction (if 8-node hexahedral elements are used, even smaller elements are required for meeting of the quality criterion).
- Recommended manner for element size in the fillet depth direction: first layer's thickness equal to element size of *a*; second layer's thickness equal to element size of *2a*; third-layer's thickness equal to element size of *3a*.

(4) In general, the rest of the crank is to be suitable for numeric stability of the solver.

(5) Drillings and holes for weight reduction have to be modelled.

(6) Submodeling may be used as long as the software requirements are fulfilled.

2.2 Material

In the FE analysis, material parameters such as Young's modulus (E) and Poisson's ratio (ν) are required, as primarily strain is calculated and stress is derived from strain through the use of Young's modulus and Poisson's ratio. Reliable values for material parameters have to be used, either as quoted in the literature or measured from representative material samples.

For steel the following is advised: $E = 2.05 \times 10^5$ MPa and $\nu = 0.3$.

2.3 Element mesh quality criteria

If the actual element mesh does not fulfil any of the following criteria in the area examined for SCF evaluation, a second calculation, with a finer mesh is to be performed.

(1) Principal -stresses criterion:

The quality of the mesh is to be assured through checking of the stress component normal to the surface of the oil bore outlet radius. With principal stresses σ_1, σ_2 and σ_3 the following criterion must be met:

$$\min\left(|\sigma_1|, |\sigma_2|, |\sigma_3|\right) < 0.03 \max\left(|\sigma_1|, |\sigma_2|, |\sigma_3|\right).$$

(2) Averaged/unaveraged -stresses criterion:

The averaged/unaveraged -stresses criterion is based on observation of the discontinuity of stress results over elements at the fillet for the calculation of the SCF: unaveraged nodal stress results calculated from each element connected to a node i are to differ less than 5% from the 100% averaged nodal stress results at this node i at the location examined.

3 *Load cases and assessment of stress*

FE calculation is to be performed for the following load cases.

3.1 Torsion

The structure is loaded in pure torsion. The surface warp at the end faces of the model is suppressed. Torque is applied to the central node, on the crankshaft axis. This node acts as the master node with six degrees of freedom, and is connected rigidly to all nodes of the end face.

The boundary and load conditions are valid for both in-line- and V- type engines, as shown in Figure III-3.1.

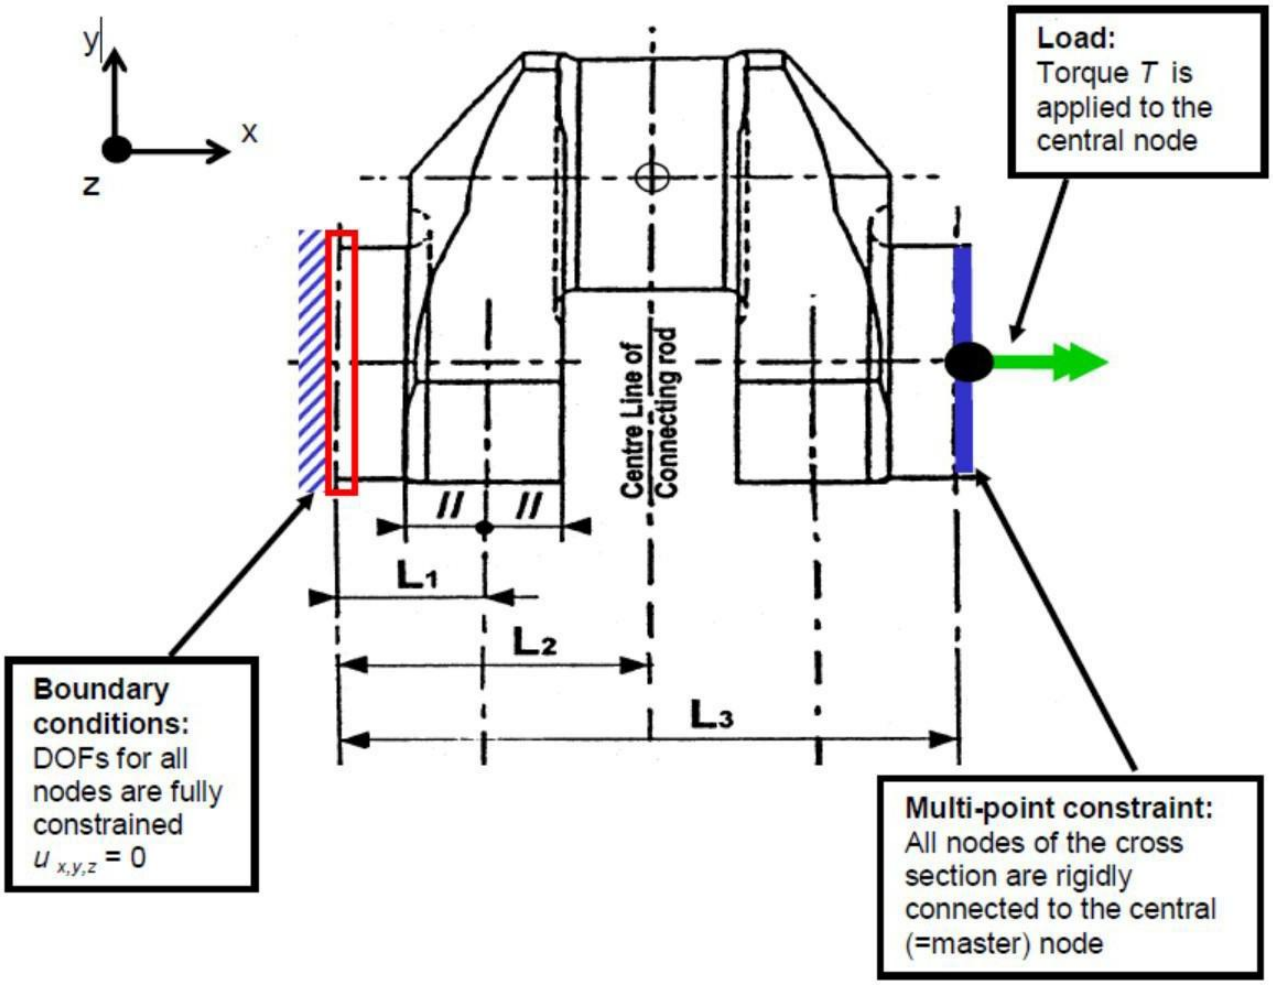

Figure III-3.1 Boundary and load conditions for the torsion load case

For all nodes in an oil bore outlet, the principal stresses are obtained and the maximum value is taken for subsequent calculation of the SCF:

$$\gamma_T = \frac{\max\left(\left|\sigma_1\right|, \left|\sigma_2\right|, \left|\sigma_3\right|\right)}{\tau_N}$$

where the nominal torsion stress τ_N referred to the crankpin is evaluated per 2.3.3 of this Appendix with torque T: $\tau_N = \frac{T}{W_P}$.

3.2 Bending

The structure is loaded in pure bending. The surface warp at the end faces of the model is suppressed.

The bending moment is applied to the central node on the crankshaft axis. This node acts as the master node, with six degrees of freedom, and is connected rigidly to all nodes of the end face.

The boundary and load conditions are valid for both in-line- and V- type engines, as shown in Figure III-3.2.

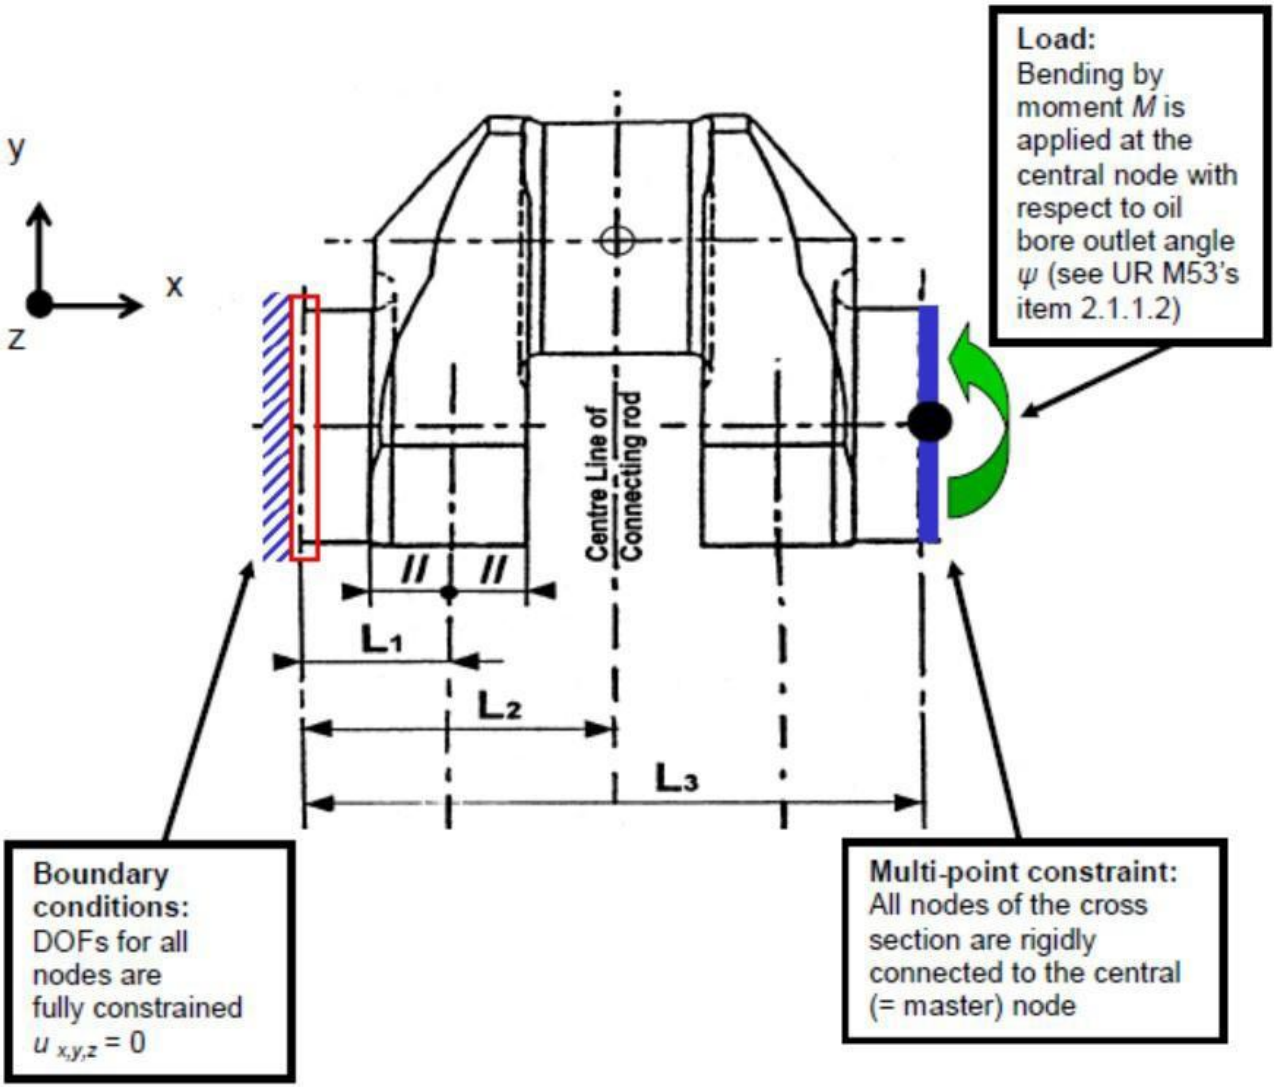

Figure III-3.2 Boundary and load conditions for the pure bending load case

For all nodes in the oil bore outlet, principal stresses are obtained and the maximum value is taken for subsequent calculation of the SCF:

$$\gamma_B = \frac{\max\left(\left|\sigma_1\right|, \left|\sigma_2\right|, \left|\sigma_3\right|\right)}{\sigma_{BON}}$$

where the nominal bending stress σ_{BON} referred to the crankpin is calculated per 2.3.1(3) of this Appendix with bending moment *M*: $\sigma_{BON} = \frac{M}{W_e}$.

Appendix 4 TYPE TEST OF DIESEL ENGINES

1 *General Requirements*

1.1 Application

1.1.1 The type testing, documented in this Appendix, is to be arranged to represent typical foreseen service load profiles, as specified by the engine builder, as well as to cover for required margins due to fatigue scatter and reasonably foreseen in-service deterioration.

1.1.2 This applies to:

(1) Parts subjected to high cycle fatigue (HCF) such as connecting rods, cams, rollers and spring tuned dampers where higher stresses may be provided by means of elevated injection pressure, cylinder maximum pressure, etc.;

(2) Parts subjected to low cycle fatigue (LCF) such as "hot" parts when load profiles such as idle − full load − idle (with steep ramps) are frequently used;

(3) Operation of the engine at limits as defined by its specified alarm system, such as running at maximum permissible power with the lowest permissible oil pressure and/or highest permissible oil inlet temperature.

1.2 Safety precautions

1.2.1 Before any test run is carried out, all relevant equipment for the safety of attending personnel, including crankcase explosive conditions protection, overspeed protection and any other shut down function, is to be made available by the manufacturer/shipyard and is to be operational, and its correct functioning is to be verified.

1.2.2 The inspection for jacketing of high-pressure fuel oil lines and proper screening of pipe connections (as required in 2.2.8 of this Appendix) is also to be carried out before the test runs.

1.2.3 Interlock test of turning gear is to be performed when installed.

1.3 Test program

1.3.1 The type testing is divided into 3 stages:

(1) Stage A − internal tests, including some of the testing made during the engine development, function testing, and collection of measured parameters and records of testing hours. The results of testing required by the Rules or specified by the designer are to be presented to ISC before starting stage B;

(2) Stage B − witnessed tests, which are the testing made in the presence of the surveyor;

(3) Stage C − component inspection, which is the inspection of engine parts to the extent as rules required.

1.3.2 The complete type testing program is subject to approval by ISC. The extent of the surveyor's presence during each stage may be agreed by both sides, but at least during stage B and C.

1.3.3 Testing prior to the witnessed type testing (stage B and C), is also considered as a part of the complete type testing program.

1.3.4 Upon completion of complete type testing (stage A through C), a type test report is to be submitted to ISC for review. The type test report is to contain:

(1) overall description of tests performed during stage A. Records are to be kept by the builder's QA management for presentation to ISC;

(2) detailed description of the load and functional tests conducted during stage B;

(3) inspection results from stage C.

1.3.5 As required in 1.1.2 of this Appendix, the type testing is to substantiate the capability of the design and its suitability for the intended operation. Special testing such as LCF and endurance testing will normally be conducted during stage A.

1.3.6 High speed engines for marine use are normally to be subjected to an endurance test of 100 hours at full load. Omission or simplification of the type test may be considered for the type approval of engines with long service experience from non-marine fields or for the extension of type approval of engines of a well-known type, in excess of the limits given in 9.10.2 of this Chapter.

Propulsion engines for high speed vessels that may be used for frequent load changes from idle to full are normally to be tested with at least 500 cycles (idle − full load − idle) using the steepest load ramp that the control system (or operation manual if not automatically controlled) permits. The duration at each end is to be sufficient for reaching stable temperatures of the hot parts.

1.4 Measurements and recordings

1.4.1 During all testing the ambient conditions (air temperature, air pressure and humidity) are to be recorded.

1.4.2 As a minimum, the following engine data are to be measured and recorded:
(1) engine r.p.m.;
(2) torque;
(3) maximum combustion pressure for each cylinder①;
(4) mean indicated pressure for each cylinder①;
(5) charging air pressure and temperature;
(6) exhaust gas temperature;
(7) fuel rack position or similar parameter related to engine load;
(8) turbocharger speed;
(9) all engine parameters that are required for control and monitoring for the intended use (propulsion, auxiliary, emergency).

Note:

① For engines where the standard production cylinder heads are not designed for such measurements, a special cylinder head made for this purpose may be used. In such a case, the measurements may be carried out as part of Stage A and are to be properly documented. Where deemed necessary e.g. for dual fuel engines, the measurement of maximum combustion pressure and mean indicated pressure may be carried out by indirect means, provided the reliability of the method is documented.

1.4.3 Calibration records for the instrumentation used to collect data as listed above are to be presented to- and reviewed by the attending Surveyor.
1.4.4 Additional measurements may be required in connection with the design assessment.

2 *Type Testing*

2.1 **Stage A − internal tests**

2.1.1 During the internal tests, the engine is to be operated at the load points important for the engine designer and the pertaining operating values are to be recorded. The load conditions to be tested are also to include the testing specified in the applicable type approval program.
2.1.2 At least the following conditions are to be tested:
(1) Normal case: The load points 25%, 50%, 75%, 100% and 110% of the maximum rated power for continuous operation, to be made along the normal (theoretical) propeller curve and at constant speed for propulsion engines (if applicable mode of operation i.e. driving controllable pitch propellers), and at constant speed for engines intended for generator sets including a test at no load and rated speed.
(2) The limit points of the permissible operating range. These limit points are to be defined by the engine manufacturer.
(3) For high speed engines, the 100 h full load test and the low cycle fatigue test apply as required in connection with the design assessment.
(4) Specific tests of parts of the engine, required by ISC or specified by the designer.

2.2 **Stage B − witnessed tests**

2.2.1 The tests listed below are to be carried out in the presence of a Surveyor. The achieved results are to be recorded and signed by the attending Surveyor after the type test is completed.
2.2.2 The overspeed test is to be carried out and is to demonstrate that the engine is not damaged by an actual engine overspeed within the overspeed shutdown system set-point. This test may be carried out at the manufacturer's choice either with or without load during the speed overshoot.
2.2.3 Load test. The engine is to be operated according to the power and speed diagram (see Figure 2.2.3). The data to be measured and recorded when testing the engine at the various load points have to include all engine parameters listed in 1.4 of this Appendix. The operating time per load point depends on the engine size (achievement of steady state condition) and on the time for collection of the operating values. Normally, an operating time of 0.5 h can be assumed per load point, however sufficient time should be allowed for visual inspection by the Surveyor.
The load points are:
(1) rated power (MCR), i.e. 100% output at 100% torque and 100% speed corresponding to load point 1, normally for 2 h with data collection with an interval of 1 h. If operation of the engine at limits as defined by its specified alarm system (e.g. at alarm levels of lub oil pressure and inlet temperature) is required, the test is to be made here;
(2) 100% power at maximum permissible speed corresponding to load point 2;
(3) maximum permissible torque (at least and normally 110%) at 100% speed corresponding to load at point 3, or maximum permissible power (at least and normally 110%) and 103.2% speed according to the

nominal propeller curve corresponding to load point 3a. Load point 3a applies to engines only driving fixed pitch propellers or water jets. Load point 3 applies to all other purposes.
Load point 3 (or 3a as applicable) is to be replaced with a load that corresponds to the specified overload and duration approved for intermittent use. This applies where such overload rating exceeds 110% of MCR. Where the approved intermittent overload rating is less than 110% of MCR, subject overload rating has to replace the load point at 100% of MCR. In such case the load point at 110% of MCR remains;
(4) minimum permissible speed at 100% torque, corresponding to load point 4;
(5) minimum permissible speed at 90% torque corresponding to load point 5. (Applicable to propulsion engines only);
(6) part loads e.g. 75%, 50% and 25% of rated power and speed according to nominal propeller curve (i.e. 90.8%, 79.3% and 62.9% speed) corresponding to points 6, 7 and 8 or at constant rated speed setting corresponding to points 9, 10 and 11, depending on the intended application of the engine;
(7) crosshead engines not restricted for use with C.P. propellers are to be tested with no load at the associated maximum permissible engine speed.
2.2.4 During all these load points, engine parameters are to be within the specified and approved values.

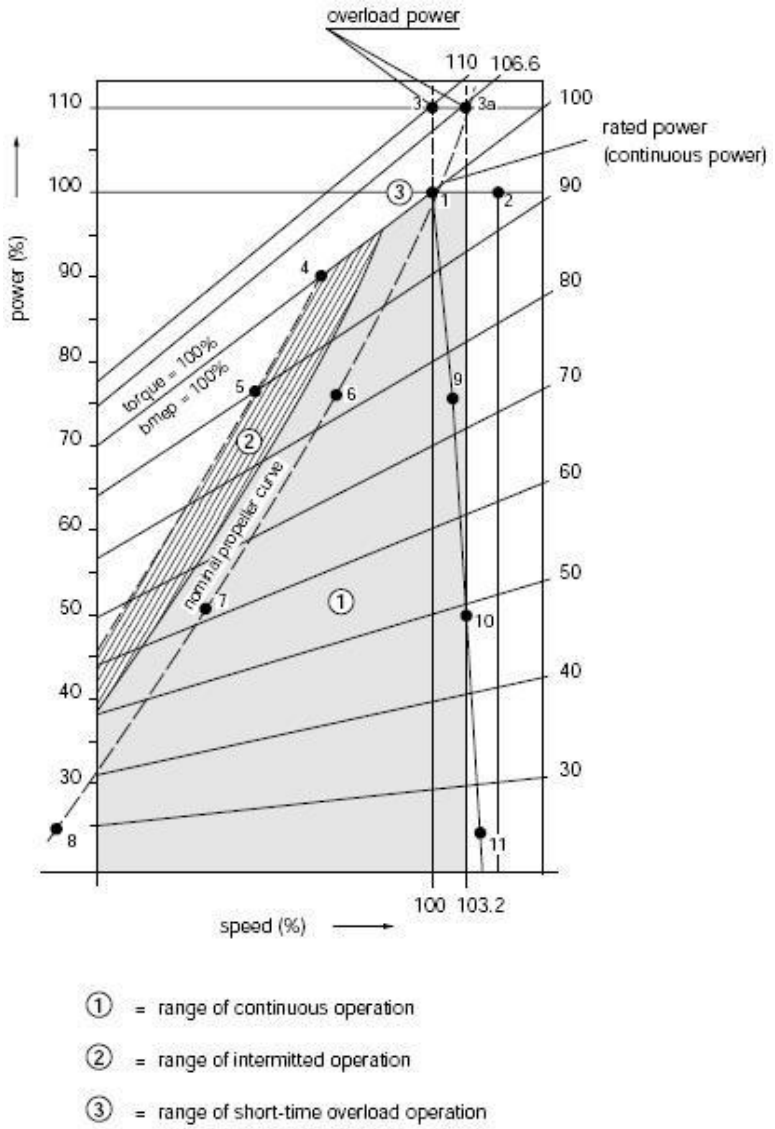

Figure 2.2.3 Diagram of power-speed

2.2.5 Operation with damaged turbocharger. For 2-stroke propulsion engines, the achievable continuous output is to be determined in the case of turbocharger damage. Engines intended for single propulsion with a fixed pitch propeller are to be able to run continuously at a speed (r.p.m.) of 40% of full speed along the theoretical propeller curve when one turbocharger is out of operation. The test can be performed by either by-passing the turbocharger, fixing the turbocharger rotor shaft or removing the rotor.

2.2.6 Functional tests are as follows:
(1) Verification of the lowest specified propulsion engine speed according to the nominal propeller curve as specified by the engine designer (even though it works on a water-brake). During this operation, no alarm is to occur.
(2) Starting tests, for non-reversible engines and/or starting and reversing tests, for reversible engines, for the purpose of determining the minimum air pressure and the consumption for a start.
(3) Governor tests: tests for compliance with 9.7.8 and 9.7.10 of this Chapter are to be carried out.
2.2.7 Integration test. For electronically controlled diesel engines, integration tests are to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes. The scope of these tests is to be agreed with ISC for selected cases based on the FMEA.
2.2.8 Fire protection measures. Verification of compliance with requirements for jacketing of high-pressure fuel oil lines, screening of pipe connections in piping containing flammable liquids and insulation of hot surfaces:
(1) The engine is to be inspected for jacketing of high-pressure fuel oil lines, including the system for the detection of leakage, and proper screening of pipe connections in piping containing flammable liquids.
(2) Proper insulation of hot surfaces is to be verified while running the engine at 100% load, alternatively at the overload approved for intermittent use. Readings of surface temperatures are to be done by use of Infrared Thermoscanning Equipment. Equivalent measurement equipment may be used when so approved by ISC. Readings obtained are to be randomly verified by use of contact thermometers.

2.3 Stage C − Opening up for Inspections
2.3.1 The crankshaft deflections are to be measured in the specified (by designer) condition.
2.3.2 High speed engines for marine use are normally to be stripped down for a complete inspection after the type test.
2.3.3 For all the other engines, after the test run, the components are to be presented for inspection as follows:
(1) piston removed and dismantled;
(2) crosshead bearing dismantled;
(3) guide planes;
(4) connecting rod bearings (big and small end) dismantled (special attention to serrations and fretting on contact surfaces with the bearing backsides);
(5) main bearing dismantled;
(6) cylinder liner in the installed condition;
(7) cylinder head, valves disassembled;
(8) cam drive gear or chain, camshaft and crankcase with opened covers. (The engine must be turnable by turning gear for this inspection.)
Note: Engines with long service experience from non-marine fields can have a reduced extent of opening.

2.3.4 One cylinder for in-line engines and two cylinders for V-engines are to be selected. For V-engines, the cylinder units are to be selected from both cylinder banks and different crank throws.
2.3.5 Where deemed necessary by the surveyor, further dismantling of the engine may be required.

Appendix 5 APPROVAL AND CERTIFICATION OF DIESEL ENGINES

1 *General Provisions*

1.1 Scope

1.1.1 The approval and certification process of a diesel engine and the documents for use during manufacture and installation, and the document flow between engine designer, classification society approval center, engine builder/licensee and surveyors are provided in this Appendix.

1.1.2 The engine plans and documents are to be submitted for approval in accordance with the requirements of 9.1.12.1 and 9.1.12.2 of this Chapter.

1.2 *Definitions*

1.2.1 Definitions relating to approval and certification of diesel engines are given in Annex 1 of this Appendix.

1.3 *Type approval certificate*

1.3.1 For each type of engine that is required to be approved, a type approval certificate is to be obtained by the engine designer. The process details for obtaining a type approval certificate are in 3.1 of this Appendix.

1.3.2 This process consists of the engine designer obtaining:

(1) drawing and specification approval;

(2) conformity of production;

(3) approval of type testing program;

(4) type testing of engines;

(5) review of the obtained type testing results;

(6) evaluation of the manufacturing arrangements;

(7) issue of a type approval certificate upon satisfactorily meeting the Rule requirements.

1.4 *Marine product certificate*

1.4.1 Each diesel engine manufactured for a shipboard application is to have a marine product certificate. The certification process details for obtaining the marine product certificate are in 3.2 of this Appendix.

1.4.2 This process consists of following steps:

(1) the engine builder/licensee obtaining design appraisal of the engine application specific documents;

(2) submitting a comparison list of the production drawings to the previously approved engine design drawings;

(3) forwarding the relevant production drawings and comparison list for the use of the Surveyors at the manufacturing plant and shipyard if necessary;

(4) engine testing; and

(5) upon satisfactorily meeting ISC Rule requirements, the issuance of an engine certificate.

1.5 *Approval of diesel engine components*

1.5.1 Components of engine designer's design which are covered by the type approval certificate of the relevant engine type are regarded as approved whether manufactured by the engine manufacturer or sub-supplied. For components of subcontractor's design, necessary approvals are to be obtained by the relevant suppliers (e.g. exhaust gas turbochargers, charge air coolers, etc.).

1.6 *Submission format of documentation*

1.6.1 The documentation is to be submitted to ISC in electronic or paper format. If the documentation is in paper format, it is to be submitted in triplicate.

2 *Document Flow for Diesel Engines*

2.1 Document flow for obtaining a type approval certificate

2.1.1 For the initial engine type, the engine designer prepares the documentation in accordance with requirements in 9.1.12.1 and 9.1.12.2 of this Chapter and forwards to ISC according to the agreed procedure for review.

2.1.2 Upon review and approval of the submitted documentation (evidence of approval), it is returned to

the engine designer.
2.1.3 The engine designer arranges for a surveyor to attend an engine type test and upon satisfactory testing ISC issues a type approval certificate.
2.1.4 A representative document flow process for obtaining a type approval certificate is shown in Annex 2 of this Appendix.

2.2 *Document flow for engine certificate*

2.2.1 The engine type must have a type approval certificate. For the first engine of a type, the type approval process and the engine certification process (ECP) may be performed simultaneously.
2.2.2 Engines to be installed in specific applications may require the engine designer/licensor to modify the design or performance requirements. The modified drawings are forwarded by the engine designer to the engine builder/licensee to develop production documentation for use in the engine manufacture in accordance with Table 1.
2.2.3 The engine builder/licensee develops a comparison list of the production documentation to the approval documentation. An example comparison list is provided in Annex 4. If there are differences in the technical content on the licensee's production drawings/documents compared to the corresponding licensor's drawings, the licensee must obtain agreement to such differences from the licensor using the template in Annex 5.
If the designer acceptance is not confirmed, the engine is to be regarded as a different engine type and is to be subjected to the complete type approval process by the licensee.
2.2.4 The engine builder/licensee is to submit the comparison list and the production documentation to ISC according to the agreed procedure for review/approval.
2.2.5 ISC returns documentation to the engine builder/licensee with confirmation that the design has been approved. This documentation is intended to be used by the engine builder/licensee and their subcontractors and attending surveyors. As the attending Surveyors may request the engine builder/licensee or their subcontractors to provide the actual documents indicated in the list, the documents are necessary to be prepared and available for the Surveyors.
2.2.6 The attending Surveyors, at the engine builder/licensee/subcontractors, will issue product certificates as necessary for components manufactured upon satisfactory inspections and tests.
2.2.7 The engine builder/licensee assembles the engine, tests the engine with a Surveyor present. An engine certificate is issued by the Surveyor upon satisfactory completion of assembly and tests.
2.2.8 A representative document flow process for obtaining an engine certificate is shown in Figure 2, Annex 2 of this Appendix.

3 *Type Approval and Certification Process*

3.1 Type approval process

3.1.1 The type approval process consists of the steps in 3.1.2 to 3.1.5. The document flow for this process is shown in Figure 1, Annex 2 of this Appendix. The documentation, as far as applicable to the type of engine, to be submitted by the engine designer/licensor to ISC is listed in 9.1.12.1 and 9.1.12.2 of this Chapter.
3.1.2 9.1.12.2 lists basic descriptive information to provide the ISC an overview of the engine's design, engine characteristics and performance. Additionally, there are requirements related to auxiliary systems for the engine's design including installation arrangements, list of capacities, technical specifications and requirements, along with information needed for maintenance and operation of the engine.
3.1.3 9.1.12.1 lists the documents and drawings, which are to be approved by ISC.
3.1.4 Design appraisal (DA) is valid as long as no substantial modifications have been implemented. Where substantial modifications have been made, the validity of the DA's may be renewed based on evidence that the design is in conformance with all current Rules and statutory regulations.
3.1.5 A type approval test is to be carried out in accordance with Appendix 4 of this Chapter and is to be witnessed by the attending surveyor. The manufacturing facility of the engine presented for the type approval test is to be assessed in accordance with Section 2 of this Chapter.
3.1.6 After the requirements in 3.1.2 through 3.1.5 have been satisfactorily completed, ISC issues a type approval certificate (TAC).
3.1.7 After the engine type has been approved for the first time, only those documents as listed in 9.1.12.1 and 9.1.12.2 of this Chapter, which have undergone substantive changes, will have to be resubmitted for consideration.
3.1.8 A renewal of type approval certificates will be granted upon submission of information in:
(1) the submission of modified documents or new documents with substantial modifications replacing

former documents compared to the previous submission(s) for DA; or
(2) a declaration that no substantial modifications have been applied since the last DA issued.
3.1.9 ISC reserves the right to limit the duration of validity of the type approval certificate. The type approval certificate will be invalid if there are substantial modifications in the design, in the manufacturing or control processes or in the characteristics of the materials unless approved in advance by ISC.
3.1.10 The assignment of documents to 9.1.12.2 for information does not preclude possible comments by ISC.
3.1.11 Where considered necessary, ISC may request further documents to be submitted. This may include details or evidence of existing type approval or proposals for a type testing program.

3.2 *Certification process*

3.2.1 The certification process consists of the steps in 3.2.2 to 3.2.7. This process is illustrated in Figure 2, Annex 2 of this Appendix showing the document flows between the engine designer/licensor, engine builder/licensee, component manufacturers, classification society approval center and local offices.
For those cases when a licensor – licensee agreement does NOT apply, an "engine designer" is to be understood as the entity that has the design rights for the engine type or is delegated by the entity having the design rights to modify the design.
The documents listed in Table 1 of this Appendix may be submitted by the engine designer (licensor) or the manufacturer/licensee.
3.2.2 Prior to the start of the engine certification process, a design appraisal is to be obtained per 3.1.2 through 3.1.4 of this Appendix for each type of engine. Each type of engine is to be provided with a type approval certificate obtained by the engine designer/licensor prior to the engine builder/licensee beginning production manufacturing. For the first engine of a type, the type approval process and the certification process may be performed simultaneously.
The engine designer/licensor reviews the documents for the application and develops, if necessary, application specific documentation for the use of the engine builder/licensee in developing engine specific production documents.
If substantive changes have been made, the affected documents are to be resubmitted to ISC.
3.2.3 Table 1 lists the production documents, which are to be submitted by the engine builder/licensee to ISC following acceptance by the engine designer/licensor. The Surveyor uses the information for inspection purposes during manufacture and testing of the engine and its components. See 2.2.3 through 2.2.6 of this Appendix.
3.2.4 If there are differences in the technical content on the licensee's production drawings/documents compared to the corresponding licensor's drawings, the licensee must provide to ISC approval center a "Confirmation of the licensor's acceptance of licensee's modifications" approved by the licensor and signed by licensee and licensor. Modifications applied by the licensee are to be provided with appropriate quality requirements. See Annex 5 of this Appendix for a sample format.
3.2.5 ISC carries out uniformity assessment on the manufacturer's production capability and quality control capability comprising manufacturing facilities and processes, machining tools, quality assurance, testing facilities, etc. Satisfactory conformance results in the issue of a class approval document.
3.2.6 In addition to the documents listed in Table 1, the engine builder/licensee is to be able to provide to the Surveyor performing the inspection upon request the relevant detail drawings, production quality control specifications and acceptance criteria. These documents are for supplemental purposes to the survey only.
3.2.7 Each engine assembly and testing procedure required according to the Rules are to be witnessed by the attending surveyor unless an Alternative Certification Scheme is agreed between manufacturer and ISC.

Documentation for the inspection of components and systems Table 1

No.	Item
1	Engine particulars as per data sheet in Annex 3
2	Material specifications of main parts with information on non-destructive material tests and pressure tests[1]
3	Bedplate, crankcase, frame, framebox, gearbox and thrust bearing bedplate of welded design, with welding details and welding instructions[2]
4	Crankshaft (including shaft coupling bolts, counterweights, including fastening), assembly and details, thrust shaft or intermediate shaft (if integral with engine)
5	Bolts and studs for main bearings, cylinder heads and exhaust valve (two stroke design) and connecting rods
6	Tie rods

No.	Item
7	Schematic layout or other equivalent documents on the engine of fuel oil system, lubricating oil system, cooling water system, starting air system and hydraulic system (for valve lift) [3]
8	Engine control and safety system
9	Shielding of high pressure fuel pipes, assembly[4]
10	Construction of accumulators for hydraulic oil and fuel oil
11	High pressure parts for fuel oil injection system[5]
12	Arrangement and details of the crankcase explosion relief valve[6]
13	Oil mist detection and/or alternative alarm arrangements
14	Cylinder head
15	Cylinder block, engine block
16	Cylinder liner
17	Counterweights (if not integral with crankshaft), including fastening
18	Connecting rod with cap, piston rod and crosshead
19	Piston, assembly[7]
20	Piston head
21	Camshaft drive, assembly[7]
22	Flywheel
23	Arrangement of foundation (for main engines only)
24	Fuel oil injection pump
25	Shielding and insulation of exhaust pipes and other parts of high temperature which may be impinged as a result of a fuel system failure, assembly
26	Construction and arrangement of dampers
27	For electronically controlled engines, assembly drawings or arrangements of control valves, high-pressure pumps, drive for high pressure pumps and valve bodies, if applicable
28	Operation and service manuals[8]
29	Test program resulting from FMEA (for engine control system)[9]
30	Production specifications for castings and welding (sequence)
31	Type approval certification for environmental tests, control components[10]
32	Quality requirements for engine production

Notes:

1. For comparison with Rule requirements for material, NDT and pressure testing as applicable.
2. For approval of materials and weld procedure specifications. The weld procedure specification is to include details of pre and post weld heat treatment, weld consumables and fit-up conditions.
3. Details of the system so far as supplied by the engine manufacturer such as: main dimensions, operating media and maximum working pressures.
4. All engines.
5. The documentation to contain specifications for pressures, pipe dimensions and materials.
6. Only for engines of a cylinder diameter of 200 mm or more or a crankcase volume of 0.6 m^3 or more.
7. Including identification (e.g. drawing number) of components.
8. Operation and service manuals are to contain maintenance requirements (servicing and repair) including details of any special tools and gauges that are to be used with their fitting/settings together with any test requirements on completion of maintenance.
9. Required for engines that rely on hydraulic, pneumatic or electronic control of fuel injection and/or valves.
10. Documents modified for a specific application are to be submitted to the classification society for approval or information.

Annex 1 Glossary

Term	Definition
Acceptance criteria	A set of values or criteria which a design, product, service or process is required to conform with, in order to be considered in compliance
Accepted	Status of a design, product, service or process, which has been found to conform to specific acceptance criteria
Alternative Certification Scheme (ACS)	A system, by which a society evaluates a manufacturer's quality assurance and quality control arrangements for compliance with Rule requirements, then authorizes a manufacturer to undertake and witness testing normally required to be done in the presence of a Surveyor. It corresponds to ISC Type approval A.
Appraisal	Evaluation by a competent body
Approval	The granting of permission for a design, product, service or process to be used for a stated purpose under specific conditions based upon a satisfactory appraisal
Assembly	Equipment or a system made up of components or parts
Assess	Determine the degree of conformity of a design, product, service, process, system or organization with identified specifications, Rules, standards or other normative documents
Audit	Planned systematic and independent examination to determine whether the activities are documented, the documented activities are implemented, and the results meet the stated objectives
Auditor	Individual who has the qualifications and experience to perform audits
Certificate	A formal document attesting to the compliance of a design, product, service or process with acceptance criteria
Certification	A procedure whereby a design, product, service or process is approved in accordance with acceptance criteria
Class approval	Approved by a Classification Society
Classification	Specific type of certification, which relates to the Rules of the relevant Classification Society
Competent body	Organization recognized as having appropriate knowledge and expertise in a specific area
Component	Part, member of equipment or system
Conformity	Where a design, product, process or service demonstrates compliance with its specific requirements
Contract	Agreement between two or more parties relating to the scope of service
Contractor	see Supplier
Customer	Party who purchases or receives goods or services from another
Design	All relevant plans, documents, calculations described in the performance, installation and manufacturing of a product
Design analysis	Investigative methodology selectively used to assess the design
Design appraisal	Evaluation of all relevant plans, calculations and documents related to the design
Design review	Part of the appraisal process to evaluate specific aspects of the design
Drawings approval / plan approval	Part of the design appraisal process which relates to the evaluation of drawings and plans
Equipment	Part of a system assembled from components
Equivalent	An acceptable, no less effective alternative to specified criteria
Evaluation	Systematic examination of the extent to which a design, product, service or process satisfies specific criteria
Examination	Assessment by a competent person to determine compliance with requirements
Inspection	Examination of a design, product service or process by an Inspector
Inspection plan	List of tasks of inspection to be performed by the Inspector
Installation	The assembling and final placement of components, equipment and subsystems to permit operation of the system
Manufacturer	Party responsible for the manufacturing and quality of the product
Manufacturing process	Systematic series of actions directed towards manufacturing a product
Manufacturing process approval	Approval of the manufacturing process adopted by the manufacturer during production of a specific product
Material	Goods supplied by one manufacturer to another manufacturer that will require further forming or manufacturing before becoming a new product
Modification	A limited change that does not affect the current approval
Modification notice	Information about a design modification with new modification index or new drawing number replacing the earlier drawing
Performance test	Technical operation where a specific performance characteristic is determined

Term	Definition
Producer	See manufacturer
Product	Result of the manufacturing process
Prototype test	Investigations on the first or one of the first new engines with regard to optimization, fine tuning of engine parameters and verification of the expected running behavior
Quality assurance	All the planned and systematic activities implemented within the quality system, and demonstrated as needed to provide adequate confidence that an entity will fulfil requirements for quality. Refer to ISO 9001
Regulation	Rule or order issued by an executive authority or regulatory agency of a government and having the force of law
Repair	Restore to original or near original condition from the results of wear and tear or damages for a product or system in service
Requirement	Specified characteristics used for evaluation purposes
Information	Additional technical data or details supplementing the drawings requiring approval
Revision	Means to record changes in one or more particulars of design drawings or specifications
Specification	Technical data or particulars which are used to establish the suitability of materials, products, components or systems for their intended use
Substantive modifications or major modifications or major changes	Design modifications, which lead to alterations in the stress levels, operational behavior, fatigue life or an effect on other components or characteristics of importance such as emissions
Subsupplier/subcontractor	One who contracts to supply material to another supplier
Supplier	One who contracts to furnish materials or design, products, service or components to a customer or user
Test	A technical operation that consists of the determination of one or more characteristics or performance of a given product, material, equipment, organism, physical phenomenon, process or service according to a specified procedure
Traceability	Ability to follow back through the design and manufacturing process to the origin
Type approval	The establishment of the acceptability of a product through the systematic: 1 evaluation of a design to determine conformance with specifications; 2 witnessing manufacture and testing of a type of product to determine compliance with the specification; 3 evaluation of the manufacturing arrangements to confirm that the product can be consistently produced in accordance with the specification
Type approval test	Last step of the type approval procedure. Test program in accordance with Appendix 4 of this Chapter
Witness	Individual physically present at a test and being able to record and give evidence about its outcome

Annex 2 Representative Document Flow Diagrams

The document flow diagrams are provided as an aid to all parties involved in the engine certification process as to their roles and responsibilities. Variations in the document flow may vary in response to unique issues with regard to various factors related to location, availability of components and surveys. In any case, the text in the Appendix takes precedence over these flow diagrams.

Annex 3 Internal Combustion Engine Approval Application Form and Data Sheet

ISC Application number (if applicable): Engine Manufacturer's Application Identification Number:

General Data	
Engine Designer: Contact Person: Address:	Engine Manufacturer(s), Licensee(s) and/or Manufacturing Sites① Name Country

1. Document purpose (select options from either 1a or 1b)	
1a. Type Approval Application	
Service Requested	Required activities②
☐ New Type Approval	• DA, TT, CoP
☐ Renew Type Approval	• CoP, if design change then amended or new certificate process to be followed
☐ Amend Type Approval	• DA & CoP, Further TT if previously approved engine has been substantively modified (as required by URM71)
☐ Design Evaluation	• DA, TT, applicable where designer does not have production facilities, Type Approval to be granted to specific production facility once associated CoP has been completed.
☐ Update TA Supplement	• Update to Supplement, only for minor changes not affecting the Type Approval Certificate
☐ Other	• e.g. National/Statutory Administration requirements, i.e. MSC.81(70), as amended, for emergency engines
For TA Cert amendments or Supplement updates, details of what is to be changed:	
For 'Other', Details of the requirements to be considered:	
1b. Addendum for Individual Engine FAT and Certification	
☐ Individual engine requiring FAT and Certification, only where the performance data for the engine being certified differs from the details provided on the original Type Approval Application. Only section 3b requires completion. Where changes to other sections are necessary, a new Type Approval application may be required.	
Reference number of Internal Combustion Engine Approval Application Form previously submitted and reference number of the Type Approval certificate	(Copy of original application form to be attached to this document)

2. Existing documentation			
Previous Class Type Approval Certificate No. or related Design Appraisal No. (if applicable)			
Formerly issued documentation for engine (E.g. previous type test reports, in-service experience justification reports, etc.)	Issuing Body:	Document Type:	Document No.:
Existing Certification (E.g. Manufacturer's quality certification ISO 9001 etc.)	Issuing Body	Document Type	Document No.

3. Design (mark all that apply)					
3a. Engine Particulars:					
Engine Type Manufactured Since③:			Number of delivered marine engines:		
Application	☐ Direct drive Propulsion (☐ Single engine / ☐ Multi-engine installation)		☐ Auxiliary (☐ Aux. Services / ☐ Electric Propulsion)		☐ Emergency
Mechanical Design	☐ 2-stroke ☐ Cross-head Cylinder bore(mm)	☐ 4-stroke ☐ Trunk-piston	☐ In-line ☐ Reversible Length of piston stroke (mm)	☐ Vee (V-angle °) ☐ Non-reversible	☐ Other ( )
Supercharging	☐ Without supercharging	☐ With supercharging ☐ Without charge air cooling ☐ Constant-pressure charging system		☐ With charge air cooling ☐ Pulsating pressure charging system	

① All parties that affect the final complete engine (e.g. manufacture, modify, adjust) are to be listed. All sites where such work is carried out may be required to complete CoP assessment.

② DA = Design Appraisal, TT = Type Test, CoP = Assessment of Conformity of Production. See 'Definitions' at the end of this application form for more information.

③ Only in case of TA Extension.

Valve operation	☐ Cam control	☐ Electronic control		
Fuel Injection	☐ Direct injection	☐ Indirect injection	☐ Cam controlled injection	☐ Electronically controlled injection

Fuel Types (Classification according to ISO 8216)	☐ Marine residual fuel	cSt (Max. kinematic viscosity at 50°C)
	☐ Marine distillate fuel	DMA, DMB, DMC
	☐ Marine distillate fuel	DMX
	☐ Low flashpoint liquid fuel (specify fuel type)	
	☐ Gas (specify gas type)	
	☐ Other (specify)	
	☐ Dual Fuel (specify combinations of fuels to be used simultaneously)	

3b. Performance Data
(Related to: Barometric pressure 1,000 mbar; Air temperature 45°C; Relative humidity 60%; Seawater temperature 32°C)

Model reference No. (if applicable)	
Max. continuous rating	kW/cyl
Rated speed	1/min
Mean indicated pressure	MPa
Mean effective pressure	MPa
Max. firing pressure	MPa
Charge air pressure	MPa
Compression ratio	-
Mean piston speed	m/s

3c. Crankshaft

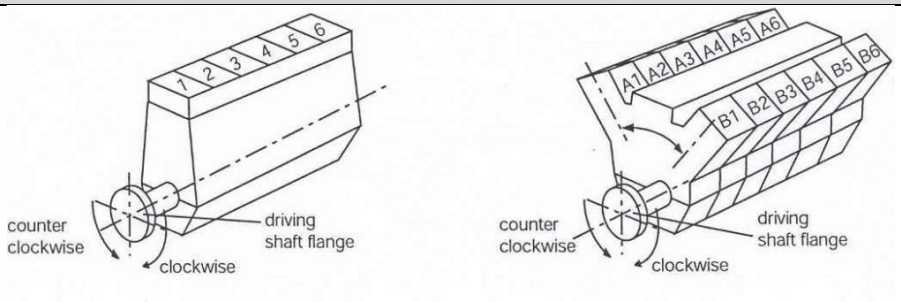
Design	☐ Solid	☐ Semi-built	☐ Built	
Method of Manufacture	☐ Cast	☐ Forged		
		☐ Slab forged	☐ Approved die forged	☐ Continuous grain flow process

State approved forge/works name:

Is the crankshaft hardened by an approved process which includes the fillet radii of crankpins and journals? ☐ Yes ☐ No

If yes, state process:

Crankshaft material specification:



U.T.S. (N/mm^2) Yield strength (N/mm^2)

Hardness value (Brinell/Vickers) Elongation (%)

Dimensional Data

If shrunk on webs, state shrinkage allowance (mm)	Yield strength of crankweb material (N/mm^2)
Centre of gravity of connecting rod from large end centre (mm)	Radius of gyration of connecting rod (mm)
Mass of each crankweb (kg)	Centre of gravity of web from journal axis (mm)
Mass of each counterweight (kg)	Centre of gravity of each counterweight from journal axis (mm)
Axial length of main bearing (mm)	Main bearing working clearance (mm)
Mass of flywheel at driving end (kg)	Mass of flywheel at opposite end (kg)
Nominal alternating torsional stress in crankpin (N/mm^2)	Nominal alternating torsional stress in crank journal (N/mm^2)
Length between centres (Total length)(mm)	

3d. Firing order

State numbering system of cylinders from left to right as per above diagrams (as applicable)

Number of cylinders	Clockwise firing order	Counter-clockwise firing order

4. Engine Ancillary Systems

4a. Turbochargers ☐ Fitted ☐ Not Fitted

Turbocharger oil supply by: ☐ Engine lub. oil system ☐ TC internal lub. oil system

No. of cylinders	No. of aux blowers	No. of charge air coolers	No. of TC	TC manufacturer & type	TC type approval certificate No.
				/ / / / / /	

4b. Speed governor

Engine application (Main/Aux/Emergency)	Manufacturer / type	Mode of operation	Type approval cert. No. (if electric / electronic gov.)
	/ / /		

4c. Overspeed protection

Independent overspeed protection available ☐ Yes ☐ No Mode of operation:

Manufacturer / type, if electronic: / Type approval certificate No.

4d. Electronic systems

Engine control and management system

Note: use Remarks section to identify when a different engine control system will be used for Type Test

Hardware: Manufacturer & Model: / Type approval certificate No.

Software: Name & Version: / Software conformity certificate No.

Additional electronic system 1: System function:

Manufacturer & type: / Type approval certificate No.

Additional electronic system 2: System function:

Manufacturer & type: / Type approval certificate No.

Additional electronic system 3: System function:

Manufacturer & type: / Type approval certificate No.

4e. Starting System

Type:

4f. Safety devices/functions

A flame arrestor or a bursting disk is installed in the starting air system: before each starting valve ☐ Yes ☐ No

in the starting air manifold ☐ Yes ☐ No

Crank case relief valves available ☐ Yes ☐ No Manufacturer / type: /

Type approval certificate No.

No. of cyl.	Total crankcase gross volume incl. attachments (m^3)	Type & size (mm) of relief valve	Relief area per relief valve (mm^2)	No. of relief valves
		/ / / /		

Method used for detection of potentially explosive crankcase condition:

☐ Oil mist detector: Manufacturer / type: / Type approval certificate No.

☐ Alternative method: (mark all that apply) ☐ crankcase pressure monitoring ☐ oil splash temperature monitoring ☐ bearing temperature monitoring ☐ recirculation arrangements ☐ other:

Cylinder overpressure warning device available ☐ Yes ☐ No

Type: Opening pressure (bar):

4g. Attached ancillary equipment(Mark all that apply)

Engine driven pumps:

☐ Main lubricating oil pump ☐ Sea cooling water pump ☐ LT-fresh cooling water pump

☐ HT-fresh cooling water pump ☐ Fuel oil booster pump ☐ Hydraulic oil pump ☐ Other ( )

Engine attached motor driven pumps:

☐ Lubricating oil pump ☐ Cooling fresh water pump ☐ Fuel oil booster pump

☐ Hydraulic oil pump ☐ Other ( )

Engine attached cooler or heater:

☐ Lubricating oil cooler ☐ Lubricating oil heater ☐ Fuel oil valve cooler

☐ Hydraulic oil cooler ☐ Cooling fresh water cooler

Engine attached filter:						
Lubricating oil filter	☐	Single	☐	Duplex	☐	Automatic
Fuel oil filter	☐	Single	☐	Duplex	☐	Automatic

5. Inclination limits (engine operation is safeguarded under the following limits)	Athwartships				Fore-and-aft			
	Static		Dynamic		Static		Dynamic	
Main & Auxiliary machinery	☐	15.0°	☐	22.5°	☐	5.0°	☐	7.5°
Emergency machinery	☐	22.5°	☐	22.5°	☐	10.0°	☐	10.0°
Emergency machinery on ships for the carriage of liquefied gas and liquid chemicals	☐	30.0°	☐	30.0°				

6. Main engine emergency operation				
At failure of one auxiliary blower, engine can be started and operated at partial load	☐	Yes	☐	No
At failure of one turbo charger, engine operation can be continued	☐	Yes	☐	No

7. References: Additional Information Attached to Application	
Document Name/Number	Summary of information contained in document

8. Further Remarks:

Completed By:

Definitions:

(1) Design Appraisal: Evaluation of all relevant plans, calculations and documents related to the design to determine compliance with the individual Societies' technical requirements. This includes requirements for all associated ancillary equipment and systems essential for the safe operation of the engine, i.e. the Complete Engine. The Design Appraisal is recorded on a Supplement to the Type Approval Certificate.

(2) **Type Testing** requires satisfactory completion of testing of the Complete Engine against the requirements applicable engine Type Testing program. Type testing is only applicable to the first in series; all engines are to complete factory acceptance and shipboard trials as defined in Appendix 6 of this Chapter.

(3) **Design Approval Certification** may be granted upon satisfactory completion of Design Appraisal and Type Testing.

(4) **Assessment of Conformity of Production** means the assessment of quality assurance, manufacturing facilities and processes and testing facilities, to confirm the manufacturer's capability to repeatedly produce the complete engine in accordance with the approved and type tested design.

(5) **Type Approval Certification** will be granted upon satisfactory completion of Design Appraisal, Type Testing and assessment of Conformity of Production of the complete engine. The Type Approval Certificate will incorporate outputs from the Design Appraisal, the Type Test and the Assessment of Conformity of Production.

(6) **Complete Engine** includes the control system and all ancillary systems and equipment referred to in the Rules that are used for safe operation of the engine and for which there are rule requirements, this includes systems allowing the use of different fuel types. The exact list of components/items that will need to be tested in together with the bare engine will depend on the specific design of the engine, its control system and the fuel(s) used may include, but are not limited to, the following:

① Turbocharger(s)
② Crank case explosion relief devices
③ Oil mist detection and alarm devices
④ Piping
⑤ Electronic monitoring and control system(s) – software and hardware

⑥ Fuel management system (where dual fuel arrangements are fitted)

⑦ Engine driven pumps

⑧ Engine mounted filters.

(7) Fuel Types: All fuels that the engine is designed to operate with are to be identified on the application form as this may impact on the requirements that are applicable for Design Appraisal and the scope of the tests required for Type Testing. Where the engine is to operate in a Dual Fuel mode, the combinations of fuel types are to be detailed. E.g. Natural Gas + DMA, Natural Gas + Marine Residual Fuel, the specific details of each fuel are to be provided as indicated in the relevant rows of the Fuel Types part of section 3a of this form.

Appendix 6 WORKS ACCEPTANCE TEST AND SHIPBOARD TRIALS OF DIESEL ENGINES①

1 *General Provisions*

1.1 Safety precautions

1.1.1 Before any test run is carried out, all relevant equipment for the safety of attending personnel is to be made available by the manufacturer / shipyard and is to be operational.

1.1.2 This applies especially to crankcase explosive conditions protection, but also to overspeed protection and any other shut down function.

1.1.3 The overspeed protective device is to be set to a value, which is not higher than the overspeed value that was demonstrated during the type test for that engine. This set point is to be verified by the surveyor.

1.2 *General requirements*

1.2.1 Before any official testing, the engines are to be run-in as prescribed by the engine manufacturer.

1.2.2 Adequate test bed facilities for loads as required are to be provided. All fluids used for testing purposes such as fuel, lubrication oil and cooling water are to be suitable for the purpose intended, e.g. they are to be clean, preheated if necessary and cause no harm to engine parts.

1.2.3 The testing consists of workshop and shipboard (quay and sea trial) testing.

1.2.4 Engines are to be inspected for:

(1) jacketing of high-pressure fuel oil lines including the system used for the detection of leakage;

(2) screening of pipe connections in piping containing flammable liquids;

(3) insulation of hot surfaces by taking random temperature readings that are to be compared with corresponding readings obtained during the type test. This is to be done while running at the rated power of engine. Use of contact thermometers may be accepted at the discretion of the attending Surveyor. If the insulation is modified subsequently to the Type Approval Test, ISC may request temperature measurements as required by Appendix 4 of this Chapter.

1.2.5 These inspections are normally to be made during the works trials, but at the discretion of ISC, parts of these inspections may be postponed to the shipboard testing.

2 *Factory Acceptance Test*

2.1 Objectives

2.1.1 The purpose of the works trials is to verify design premises such as power, safety against fire, adherence to approved limits (e.g. maximum pressure), and functionality and to establish reference values or base lines for later reference in the operational phase.

2.2 *Records*

2.2.1 The following environmental test conditions are to be recorded:

(1) Ambient air temperature;

(2) Ambient air pressure;

(3) Atmospheric humidity.

2.2.2 For each required load point, the following parameters are normally to be recorded:

(1) Power and speed;

(2) Fuel index (or equivalent reading);

(3) Maximum combustion pressures (only when the cylinder heads installed are designed for such measurement);

(4) Exhaust gas temperature before turbine and from each cylinder (to the extent that monitoring is required in 9.6.2 of this Chapter);

(5) Charge air temperature;

(6) Charge air pressure;

(7) Turbocharger speed (to the extent that monitoring is required in 9.6.2 of this Chapter).

2.2.3 Calibration records for the instrumentation are, upon request, to be presented to the attending

---

① In this Appendix, the requirements for works acceptance test are applicable to diesel engines with an application for certification dated on or after 1 July 2016, and those for shipboard trials are applicable to diesel engines:
(1) with an application for certification dated on or after 1 July 2016; or
(2) installed on ships contracted for construction on or after 1 July 2016.

Surveyor.

2.2.4 For all stages at which the engine is to be tested, the pertaining operational values are to be measured and recorded by the engine manufacturer. All results are to be compiled in an acceptance protocol to be issued by the engine manufacturer. This also includes crankshaft deflections if considered necessary by the engine designer.

2.2.5 In each case, all measurements conducted at the various load points are to be carried out at steady state operating conditions. However, for all load points provision are to be made for time needed by the Surveyor to carry out visual inspections. The readings for MCR, i.e. 100% power (rated maximum continuous power at corresponding rpm) are to be taken at least twice at an interval of normally 30 min.

2.3 *Test loads*

2.3.1 Test loads for various engine applications are given in 2.3.2 to 2.3.6.

2.3.2 Propulsion engines driving propeller or impeller only.

(1) 100% power (MCR) at corresponding speed n_0: at least 60 min.

(2) 110% power at engine speed $1.032n_0$: Records to be taken after 15 min or after steady conditions have been reached, whichever is shorter.

Note: Only required once for each different engine/turbocharger configuration.

(3) Approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.

(4) 90% (or normal continuous cruise power), 75%, 50% and 25% power in accordance with the nominal propeller curve, the sequence to be selected by the engine manufacturer.

(5) Reversing manoeuvers (if applicable).

Note: After running on the test bed, the fuel delivery system is to be so adjusted that overload power cannot be given in service, unless intermittent overload power is approved by ISC. In that case, the fuel delivery system is to be blocked to that power.

2.3.3 Engines driving generators for electric propulsion:

(1) 100% power (MCR) at corresponding speed n_0: at least 60 min.

(2) 110% power at engine speed n_0: 15 min after having reached steady conditions.

(3) Governor tests for compliance with 9.7.8 and 9.7.10 of this Chapter are to be carried out.

(4) 75%, 50% and 25% power and idle, the sequence to be selected by the engine manufacturer.

Note: After running on the test bed, the fuel delivery system is to be adjusted so that full power plus a 10% margin for transient regulation can be given in service after installation onboard. The transient overload capability is required so that the required transient governing characteristics are achieved also at 100% loading of the engine, and so that the protection system utilized in the electric distribution system can be activated before the engine stalls.

2.3.4 Engines driving generators for auxiliary purposes:

Tests are to be performed as in 2.3.3.

2.3.5 Propulsion engines also driving power take off (PTO) generator.

(1) 100% power (MCR) at corresponding speed n_0: at least 60 min.

(2) 110% power at engine speed n_0: 15 min after having reached steady conditions.

(3) Approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.

(4) 90% (or normal continuous cruise power), 75%, 50% and 25% power in accordance with the nominal propeller curve or at constant speed n_0, the sequence to be selected by the engine manufacturer.

Note: After running on the test bed, the fuel delivery system is to be adjusted so that full power plus a margin for transient regulation can be given in service after installation onboard. The transient overload capability is required so that the electrical protection of downstream system components is activated before the engine stalls. This margin may be 10% of the engine power but at least 10% of the PTO power.

2.3.6 Engines driving auxiliaries

(1) 100% power (MCR) at corresponding speed n_0: at least 30 min.

(2) 110% power at engine speed n_0: 15 min after having reached steady conditions.

(3) Approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.

(4) For variable speed engines, 75%, 50% and 25% power in accordance with the nominal power consumption curve, the sequence to be selected by the engine manufacturer.

Note: After running on the test bed, the fuel delivery system is normally to be so adjusted that overload power cannot be delivered in service, unless intermittent overload power is approved. In that case, the fuel delivery system is to be blocked to that power.

2.4 *Turbocharger matching with engine*

2.4.1 Turbochargers are to have a compressor characteristic that allows the engine, for which it is intended, to operate without surging during all operating conditions and also after extended periods in operation. For abnormal, but permissible, operation conditions, such as misfiring and sudden load reduction, no continuous surging is to occur.

Notes: Surging and continuous surging are defined as follows:

① Surging means the phenomenon, which results in a high pitch vibration of an audible level or explosion-like noise from the scavenger area of the engine.

② Continuous surging means that surging happens repeatedly and not only once.

2.4.2 Category C turbochargers used on propulsion engines are to be checked for surge margins during the engine workshop testing as specified below. These tests may be waived if successfully tested earlier on an identical configuration of engine and turbocharger (including same nozzle rings).

For 4-stroke engines, the following are to be performed without indication of surging:

− with maximum continuous power and speed (=100%), the speed is to be reduced with constant torque (fuel index) down to 90% power;

− with 50% power at 80% speed (= propeller characteristic for fixed pitch), the speed is to be reduced to 72% while keeping constant torque (fuel index).

For 2-stroke engines, the surge margin is to be demonstrated by at least one of the following methods:

(1) The engine working characteristic established at workshop testing of the engine is to be plotted into the compressor chart of the turbocharger (established in a test rig). There is to be at least 10% surge margin in the full load range, i.e. working flow is to be 10% above the theoretical (mass) flow at surge limit (at no pressure fluctuations).

(2) Sudden fuel cut-off to at least one cylinder is not to result in continuous surging and the turbocharger is to be stabilized at the new load within 20 seconds. For applications with more than one turbocharger, the fuel is to be cut-off to the cylinders closest upstream to each turbocharger. This test is to be performed at two different engine loads:

− the maximum power permitted for one cylinder misfiring;

− the engine load corresponding to a charge air pressure of about 0.6 bar (but without auxiliary blowers running).

(3) No continuous surging and the turbocharger is to be stabilized at the new load within 20 seconds when the power is abruptly reduced from 100% to 50% of the maximum continuous power.

2.5 *Integration tests*

2.5.1 For electronically controlled engines, integration tests are to be made to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes and the tests considered as a system are to be carried out at the works. If such tests are technically unfeasible at the works, however, these tests may be conducted during sea trial. The scope of these tests is to be agreed with ISC for selected cases based on the FMEA.

2.6 *Component inspections*

2.6.1 Random checks of components to be presented for inspection after works trials are left to the discretion of the surveyor.

3 *Shipboard Trials*

3.1 Objectives

3.1.1 The purpose of the shipboard testing is to verify compatibility with power transmission and driven machinery in the system, control systems and auxiliary systems necessary for the engine and integration of engine/shipboard control systems, as well as other items that had not been dealt with in the FAT (Factory Acceptance Testing).

3.2 *Starting capacity*

3.2.1 Starting manoeuvers are to be carried out in order to verify that the capacity of the starting media satisfies the required number of start attempts.

3.3 *Monitoring and alarm system*

3.3.1 The monitoring and alarm systems are to be checked to the full extent for all engines, except items already verified during the works trials.

3.4 *Test loads*

3.4.1 Test loads for various engine applications are given in 3.4.3 to 3.4.7. In addition, the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

3.4.2 The suitability of the engine to operate on fuels intended for use is to be demonstrated.

Note: Tests other than those listed in 3.4.3 to 3.4.7 may be required by statutory instruments (e.g. EEDI verification).

3.4.3 Propulsion engines driving fixed pitch propeller or impeller:

(1) At rated engine speed n_0: at least 4 h.

(2) At engine speed $1.032n_0$ (if engine adjustment permits, see 2.3.2 of this Appendix): 30 min.

(3) At approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer

(4) Minimum engine speed to be determined.

(5) The ability of reversible engines to be operated in reverse direction is to be demonstrated.

Note: During stopping tests according to resolution MSC.137(76), see 3.5.1 for additional requirements in the case of a barred speed range.

3.4.4 Propulsion engines driving controllable pitch propellers:

(1) At rated engine speed n_0 with a propeller pitch leading to rated engine power (or to the maximum achievable power if 100% cannot be reached): at least 4 h.

(2) At approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.

(3) With reverse pitch suitable for manoeuvring, see 3.5.1 for additional requirements in the case of a barred speed range.

3.4.5 Engine(s) driving generator(s) for electrical propulsion and/or main power supply:

(1) At 100% power (rated electrical power of generator): at least 60 min.

(2) At 110% power (rated electrical power of generator): at least 10 min.

Note: Each engine is to be tested 100% electrical power for at least 60 min and 110% of rated electrical power of the generator for at least 10 min. This may, if possible, be done during the electrical propulsion plant test, which is required to be tested with 100% propulsion power (i.e. total electric motor capacity for propulsion) by distributing the power on as few generators as possible. The duration of this test is to be sufficient to reach stable operating temperatures of all rotating machines or for at least 4 h. When some of the gen. set(s) cannot be tested due to insufficient time during the propulsion system test mentioned above, those required tests are to be carried out separately.

(3) Demonstration of the generator prime movers' and governors' ability to handle load steps as described in 9.7.10 of this Chapter.

3.4.6 Propulsion engines also driving power take off (PTO) generator:

(1) 100% engine power (MCR) at corresponding speed n_0: at least 4 h.

(2) 100% propeller branch power at engine speed n_0 (unless already covered in (1)): 2 h.

(3) 100% PTO branch power at engine speed n_0: at least 1 h.

3.4.7 Engines driving auxiliaries:

(1) 100% power (MCR) at corresponding speed n_0: at least 30 min.

(2) Approved intermittent overload: testing for duration as approved.

3.5 *Torsional vibrations*

3.5.1 Where a barred speed range (bsr) is required, passages through this bsr, both accelerating and decelerating, are to be demonstrated. The times taken are to be recorded and are to be equal to or below those times specified in the approved documentation, if any. This also includes when passing through the bsr in reverse rotational direction, especially during the stopping test.

Note: Applies both for manual and automatic passing-through systems.

The ship's draft and speed during all these demonstrations is to be recorded. In the case of a controllable pitch propeller, the pitch is also to be recorded.

The engine is to be checked for stable running (steady fuel index) at both upper and lower borders of the bsr. Steady fuel index means an oscillation range less than 5% of the effective stroke (idle to full index).

Appendix 7 TYPE TESTING PROCEDURE FOR CRANKCASE EXPLOSION RELIEF VALVES

1 *Scope*

1.1 To specify type tests and identify standard test conditions using methane gas and air mixture to demonstrate that relevant requirements of ISC are satisfied for crankcase explosion relief valves intended to be fitted to engines and gear cases.

1.2 This test procedure is only applicable to explosion relief valves fitted with flame arresters.

Note: Where internal oil wetting of a flame arrester is a design feature of an explosion relief valve, alternative testing arrangements that demonstrate compliance with this Appendix may be proposed by the manufacturer. The alternative testing arrangements are to be agreed by ISC.

2 *Applicable standards or rules*

2.1 ISO 16852.

2.2 ISO/IEC 17025.

2.3 ISO 12100.

2.4 VDI 3673-1.

2.5 IMO MSC/Circular 677 as amended by MSC/Circ.1009 and MSC.1/Circ.1324.

3 *Purpose*

3.1 The purpose of type testing crankcase explosion relief valves is fourfold:

(1) to verify the effectiveness of the flame arrester;

(2) to verify that the valve closes after an explosion;

(3) to verify that the valve is gas/air tight after an explosion;

(4) to establish the level of overpressure protection provided by the valve.

4 *Test facilities*

4.1 Test houses carrying out type testing of crankcase explosion relief valves are to meet the following requirements specified in 4.1.1 to 4.1.11.

4.1.1 The test houses where testing is carried out are to be accredited to a recognized national or international standard, e.g. ISO/IEC 17025, and are to be acceptable to ISC.

4.1.2 The test facilities are to be equipped so that they can perform and record explosion testing in accordance with this procedure.

4.1.3 The test facilities are to have equipment for controlling and measuring a methane gas in air concentration within a test vessel to an accuracy of ± 0.1%.

4.1.4 The test facilities are to be capable of effective point-located ignition of a methane gas in air mixture.

4.1.5 The pressure measuring equipment is to be capable of measuring the pressure in the test vessel in at least two positions, one at the valve and the other at the test vessel centre. The measuring arrangements are to be capable of measuring and recording the pressure changes throughout an explosion test at a frequency recognizing the speed of events during an explosion. The result of each test is to be documented by video recording and by recording with a heat sensitive camera.

4.1.6 The test vessel for explosion testing is to have documented dimensions. The dimensions are to be such that the vessel is not “pipe like” with the distance between dished ends being not more than 2.5 times its diameter. The internal volume of the test vessel is to include any standpipe arrangements.

4.1.7 The test vessel is to be provided with a flange, located centrally at one end perpendicular to the vessel longitudinal axis, for mounting the explosion relief valve. The test vessel is to be arranged in an orientation consistent with how the valve will be installed in service, i.e., in the vertical plane or the horizontal plane.

4.1.8 A circular plate is to be provided for fitting between the pressure vessel flange and valve to be tested with the following dimensions:

(1) outside diameter of 2 times the outer diameter of the valve top cover;

(2) internal bore having the same internal diameter as the valve to be tested.

4.1.9 The test vessel is to have connections for measuring the methane in air mixture at the top and bottom.

4.1.10 The test vessel is to be provided with a means of fitting an ignition source at a position specified in 5.3 of this Appendix.

4.1.11 The test vessel volume is to be as far as practicable, related to the size and capability of the relief valve to be tested. In general, the volume is to correspond to the relevant requirements in 9.7.4.6 of this Chapter for the free area of explosion relief valve to be not less than 115 cm^2/m^3 of crankcase gross volume.

Notes:

① This means that the testing of a valve having 1,150 cm^2 of free area, would require a test vessel with a volume of 10 m^3.

② Where the free area of relief valves is greater than 115 cm^2/m^3 of the crankcase gross volume, the volume of the test vessel is to be consistent with the design ratio.

③ In no case is the volume of the test vessel to vary by more than -10% to +15% from the design cm^2/m^3 volume ratio.

5 *Explosion test process*

5.1 All explosion tests to verify the functionality of crankcase explosion relief valves are to be carried out using an air and methane mixture with a volumetric methane concentration of 9.5%±0.5%. The pressure in the test vessel is to be not less than atmospheric and is not to exceed the opening pressure of the relief valve.

5.2 The concentration of methane in the test vessel is to be measured at the top and bottom of the vessel and these concentrations are not to differ by more than 0.5%.

5.3 The ignition of the methane and air mixture is to be made at the centerline of the test vessel at a position approximately one third of the height or length of the test vessel opposite to where the valve is mounted.

5.4 The ignition is to be made using a maximum 100 J explosive charge.

6 *Valves to be tested*

6.1 The valves used for type testing (including testing specified in 6.3) are to be selected from the manufacturer's normal production line for such valves by the Surveyor witnessing the tests.

6.2 For approval of a specific valve size, three valves are to be tested in accordance with 6.3 and 7.1 to 7.2 of this Appendix. For approval of a series of valves, 9.1 to 9.4 of this Appendix are to be complied with.

6.3 The valves selected for type testing are to have been previously tested at the manufacturer's works to demonstrate that the opening pressure is in accordance with the specification within a tolerance of ±20% and that the valve is air tight at a pressure below the opening pressure for at least 30 seconds.

Note: This test is to verify that the valve is air tight following assembly at the manufacturer's works and that the valve begins to open at the required pressure demonstrating that the correct spring has been fitted.

6.4 The type testing of valves is to recognize the orientation in which they are intended to be installed on the engine or gear case. Three valves of each size are to be tested for each intended installation orientation, i.e. in the vertical and/or horizontal positions.

7 *Method*

7.1 The following requirements of 7.1.1 to 7.1.5 are to be satisfied at explosion testing.

7.1.1 The explosion testing is to be witnessed by a Surveyor.

7.1.2 Where valves are to be installed on an engine or gear case with shielding arrangements to deflect the emission of explosion combustion products, the valves are to be tested with the shielding arrangements fitted.

7.1.3 Successive explosion testing to establish a valve's functionality is to be carried out as quickly as possible during stable weather conditions.

7.1.4 The pressure rise and decay during all explosion testing is to be recorded.

7.1.5 The external condition of the valves is to be monitored during each test for indication of any flame release by video and heat sensitive camera.

7.2 The explosion testing is to be in three stages as specified in 7.2.1 to 7.2.3 for each valve that is required to be approved as being type tested.

7.2.1 Stage 1: Two explosion tests are to be carried out in the test vessel with the circular plate described in 4.1.8 fitted and the opening in the plate covered by a 0.05 mm thick polythene film.

Note: These tests establish a reference pressure level for determination of the capability of a relief valve in terms of pressure rise in the test vessel, see 8.1.6 of this Appendix.

7.2.2 Stage 2:

(1) Two explosion tests are to be carried out on three different valves of the same size. Each valve is to be mounted in the orientation for which approval is sought, i.e. in the vertical or horizontal position with the circular plate described in 4.1.8 located between the valve and pressure vessel mounting flange.

(2) The first of the two tests on each valve is to be carried out with a 0.05mm thick polythene bag, having a minimum diameter of three times the diameter of the circular plate and volume not less than 30% of the test

vessel, enclosing the valve and circular plate. Before carrying out the explosion test, the polythene bag is to be empty of air. The polythene bag is required to provide a readily visible means of assessing whether there is flame transmission through the relief valve following an explosion consistent with the requirements of the standards identified in 2.1 to 2.5 of this Appendix.

Note: During the test, the explosion pressure will open the valve and some unburned methane/air mixture will be collected in the polythene bag. When the flame reaches the flame arrester and if there is flame transmission through the flame arrester, the methane/air mixture in the bag will be ignited and this will be visible.

(3) Provided that the first explosion test successfully demonstrated that there was no indication of combustion outside the flame arrester and there are no visible signs of damage to the flame arrester or valve, a second explosion test without the polythene bag arrangement is to be carried out as quickly as possible after the first test. During the second explosion test, the valve is to be visually monitored for any indication of combustion outside the flame arrester and video records are to be kept for subsequent analysis. The second test is required to demonstrate that the valve can still function in the event of a secondary crankcase explosion.

(4) After each explosion, the test vessel is to be maintained in the closed condition for at least 10 seconds to enable the tightness of the valve to be ascertained. The tightness of the valve can be verified during the test from the pressure/time records or by a separate test after completing the second explosion test.

7.2.3 Stage 3: Carry out two further explosion tests as described in Stage 1. These further tests are required to provide an average baseline value for assessment of pressure rise, recognizing that the test vessel ambient conditions may have changed during the testing of the explosion relief valves in Stage 2.

8 *Assessment and records*

8.1 For the purposes of verifying compliance with the requirements of this Appendix, the assessment and records of the valves used for explosion testing are to address the requirements as specified in 8.1.1 to 8.1.9.

8.1.1 The valves to be tested are to have evidence of design appraisal/approval by ISC witnessing tests.

8.1.2 The designation, dimensions and characteristics of the valves to be tested are to be recorded. This is to include the free area of the valve and of the flame arrester and the amount of valve lift at 0.02 MPa.

8.1.3 The test vessel volume is to be determined and recorded.

8.1.4 For acceptance of the functioning of the flame arrester, there is not to be any indication of flame or combustion outside the valve during an explosion test. This should be confirmed by the test laboratory taking into account measurements from the heat sensitive camera.

8.1.5 The pressure rise and decay during an explosion is to be recorded, with indication of the pressure variation showing the maximum overpressure and steady underpressure in the test vessel during testing. The pressure variation is to be recorded at two points in the pressure vessel.

8.1.6 The effect of an explosion relief valve in terms of pressure rise following an explosion is ascertained from maximum pressures recorded at the centre of the test vessel during the three stages. The pressure rise within the test vessel due to the installation of a relief valve is the difference between average pressure of the four explosions from Stages 1 and 3 and the average of the first tests on the three valves in Stage 2. The pressure rise is not to exceed the limit specified by the manufacturer.

8.1.7 The valve tightness is to be ascertained by verifying from the records at the time of testing that an underpressure of at least 0.3 bar is held by the test vessel for at least 10 seconds following an explosion. This test is to verify that the valve has effectively closed and is reasonably gas-tight following dynamic operation during an explosion.

8.1.8 After each explosion test specified in 7.2.2, the external condition of the flame arrester is to be examined for signs of serious damage and/or deformation that may affect the operation of the valve.

8.1.9 After completing the explosion tests, the valves are to be dismantled and the condition of all components ascertained and documented. In particular, any indication of valve sticking or uneven opening that may affect operation of the valve is to be noted. Photographic records of the valve condition are to be taken and included in the report.

9 *Design series qualification*

9.1 The qualification of quenching devices to prevent the passage of flame can be evaluated for other similar devices of identical type where one device has been tested and found satisfactory.

9.2 The quenching ability of a flame arrester depends on the total mass of quenching lamellas/mesh. Provided the materials, thickness of materials, depth of lamellas/thickness of mesh layer and the quenching gaps are the same, then the same quenching ability can be qualified for different sizes of flame arresters subject to the following requirements being satisfied.

$$\frac{n_1}{n_2} = \sqrt{\frac{S_1}{S_2}}$$

$$\frac{A_1}{A_2} = \frac{S_1}{S_2}$$

where: n_1 = total depth of flame arrester corresponding to the number of lamellas of size 1 quenching device for a valve with a relief area equal to S_1;

n_2 = total depth of flame arrester corresponding to the number of lamellas of size 2 quenching device for a valve with a relief area equal to S_2;

A_1 = free area of quenching device for a valve with a relief area equal to S_1;

A_2 = free area of quenching device for a valve with a relief area equal to S_2.

9.3 The qualification of explosion relief valves of larger sizes than that which has been previously satisfactorily tested in accordance with 7 and 8 of this Appendix can be evaluated, where valves are of identical type and have identical features of construction, in accordance with 9.3.1 to 9.3.3:

9.3.1 The free area of a larger valve does not exceed three times +5% that of the valve that has been satisfactorily tested.

9.3.2 One valve of the largest size, subject to 9.3.1, requiring qualification is subject to satisfactory testing required by 6.3 and 7.2.2 except that a single valve will be accepted in 7.2.2(1) and the volume of the test vessel is not to be less than one third of the volume required by 4.1.11.

9.3.3 The assessment and records are to be in accordance with Section 8 of this Appendix noting that 8.1.6 will only be applicable to Stage 2 for a single valve.

9.4 The qualification of explosion relief valves of smaller sizes than that which has been previously satisfactorily tested in accordance with Sections 7 and 8 of this Appendix can be evaluated, where valves are of identical type and have identical features of construction , in accordance with 9.4.1 to 9.4.3:

9.4.1 The free area of a smaller valve is not less than one third of the valve that has been satisfactorily tested.

9.4.2 One valve of the smallest size, subject to 9.4.1, requiring qualification is subject to satisfactory testing required by 6.3 and 7.2.2 except that a single valve will be accepted in 7.2.2(1) and the volume of the test vessel is not to be more than the volume required by 4.1.11.

9.4.3 The assessment and records are to be in accordance with Section 8 of this Appendix noting that 8.1.6 will only be applicable to Stage 2 for a single valve.

10 *The report*

10.1 The test facility is to deliver a full report that includes the following information and documents specified in 10.1.1 to 10.1.8.

10.1.1 Test specification.

10.1.2 Details of test pressure vessel and valves tested.

10.1.3 The orientation in which the valve was tested (vertical or horizontal position).

10.1.4 Methane in air concentration for each test.

10.1.5 Ignition source.

10.1.6 Pressure curves for each test.

10.1.7 Video recordings of each valve test.

10.1.8 The assessment and records stated in Section 8 of this Appendix.

11 *Approval*

11.1 The approval of an explosion relief valve is at the discretion of ISC based on the appraisal plans and particulars and the test facility's report of the results of type testing.

Appendix 8 TYPE TESTING PROCEDURE FOR CRANKCASE OIL MIST DETECTION AND ALARM EQUIPMENT

1 *Scope*

1.1 To specify the tests required to demonstrate that crankcase oil mist detection and alarm equipment intended to be fitted to diesel engines satisfy the requirements of ISC rules.

Note: This test procedure is also applicable to oil mist detection and alarm equipment intended for gear cases.

2 *Applicable standards or rules*

2.1 ISC Guidelines for Type Approval Test of Electric and Electronic Products, 2006.

3 *Purpose*

3.1 The purpose of type testing crankcase oil mist detection and alarm equipment is seven fold:

(1) to verify the functionality of the system;
(2) to verify the effectiveness of the oil mist detectors;
(3) to verify the accuracy of oil mist detectors;
(4) to verify the alarm set points;
(5) to verify time delays between oil mist leaving the source and alarm activation;
(6) to verify functional failure detection;
(7) to verify the influence of optical obscuration on detection.

4 *Test facilities*

4.1 Test houses carrying out type testing of crankcase oil mist detection and alarm equipment are to satisfy the following criteria:

(1) A full range of facilities for carrying out the environmental and functionality tests required by this procedure is to be available and be acceptable to ISC.

(2) The test house that verifies the functionality of the equipment is to be equipped so that it can control, measure and record oil mist concentration levels in terms of mg/*l* to an accuracy of ±10% in accordance with this procedure.

(3) When verifying the functionality, test houses are to consider the possible hazards associated with the generation of the oil mist required and take adequate precautions. Use of low toxicity, low hazard oils as used in other applications is accepted, provided it is demonstrated to have similar properties to SAE 40 monograde mineral oil specified in this Appendix.

5 *Equipment testing*

5.1 The range of tests is to include the items specified in 5.1.1 to 5.1.2:

5.1.1 For the alarm/monitoring panel:

(1) functional tests described in 6.1 to 6.8 of this Appendix;
(2) electrical power supply failure test;
(3) power supply variation test;
(4) dry heat test;
(5) damp heat test;
(6) vibration test;
(7) EMC test;
(8) insulation resistance test;
(9) high voltage test;
(10) static and dynamic inclinations, if moving parts are contained.

5.1.2 For the detectors:

(1) functional tests described in 6.1 to 6.8 of this Appendix;
(2) electrical power supply failure test;
(3) power supply variation test;
(4) dry heat test;
(5) damp heat test;
(6) vibration test;
(7) EMC test where susceptible;
(8) insulation resistance test;
(9) high voltage test;

(10) static and dynamic inclinations.

6 *Functional tests*

6.1 All tests to verify the functionality of crankcase oil mist detection and alarm equipment are to be carried out in accordance with 6.2 to 6.6 with an oil mist concentration in air, known in terms of mg/*l* to an accuracy of ±10%.

6.2 The concentration of oil mist in the test chamber is to be measured in the top and bottom of the chamber and these concentrations are not to differ by more than 10%. See also 8.1.1.1 of this Appendix.

6.3 The oil mist monitoring arrangements are to be capable of detecting oil mist in air concentrations of:

- between 0 and 10% of the lower explosive limit (LEL); or
- between 0 and *x*%, *x*% is a percentage of weight of oil in air determined by the manufacturer based on the sensor measurement method (e.g. obscuration or light scattering) that is acceptable to ISC taking into account the alarm level specified in 6.4.

Note: The LEL corresponds to an oil mist concentration of approximately 50 mg/*l* (4.1% weight of oil in air mixture).

6.4 The alarm set point for oil mist concentration in air is to provide an alarm at a maximum level corresponding to not more than 5% of the LEL or approximately 2.5 mg/*l*.

6.5 Where alarm set points can be altered, the means of adjustment and indication of set points are to be verified against the equipment manufacturer's instructions.

6.6 The performance of the detector which can measure and output the oil mist concentration, in mg/*l*, is to be demonstrated. This is to include the following:

(1) range;

(2) resolution;

(3) sensitivity.

Notes:

Sensitivity means quotient of the change in an indication of a measuring system and the corresponding change in a value of a quantity being measured.

Resolution means smallest change in a quantity being measured that causes a perceptible change in the corresponding indication.

6.7 Where oil mist is drawn into a detector via piping arrangements, the time delay between the sample leaving the crankcase and operation of the alarm is to be determined for the longest and shortest lengths of pipes recommended by the manufacturer. The pipe arrangements are to be in accordance with the manufacturer's instructions/recommendations. Piping is to be arranged to prevent pooling of oil condensate which may cause a blockage of the sampling pipe over time.

6.8 It is to be demonstrated that the openings of detector equipment does not become occluded or blocked under continuous splash and spray of engine lubricating oil, as may occur in the crankcase atmosphere. Testing is to be in accordance with arrangements proposed by the manufacturer and agreed by ISC. The temperature, quantity and angle of impact of the oil to be used is to be declared and their selection justified by the manufacturer.

6.9 Detector equipment may be exposed to water vapour from the crankcase atmosphere which may affect the sensitivity of the equipment and it is to be demonstrated that exposure to such conditions will not affect the functional operation of the detector equipment. Where exposure to water vapour and/or water condensation has been identified as a possible source of equipment malfunctioning, testing is to demonstrate that any mitigating arrangements such as heating are effective. Testing is to be in accordance with arrangements proposed by the manufacturer and agreed by ISC.

Note: This testing is in addition to that required by 5.1.2(5) and is concerned with the effects of condensation caused by the detection equipment being at a lower temperature than the crankcase atmosphere.

6.10 It is to be demonstrated that an indication is given where lenses fitted in the equipment and used in determination of the oil mist level have been partially obscured to a degree that will affect the reliability of the information and alarm indication.

7 *Detectors and alarm equipment to be tested*

7.1 The detectors and alarm equipment selected for the type testing are to be selected from the manufacturer's normal production line by the Surveyor witnessing the tests.

7.2 Two detectors are to be tested. One is to be tested in clean condition and the other in a condition representing the maximum level of lens obscuration specified by the manufacturer.

8 *Method*

8.1 The following requirements are to be satisfied at type testing:

8.1.1 Oil mist generation is to satisfy 8.1.1.1 to 8.1.1.5.

8.1.1.1 The ambient temperature in and around the test chamber is to be at the standard atmospheric

conditions defined in ISC Guidelines for Type Approval Test of Electric and Electronic Products before any test run is started.

8.1.1.2 Oil mist is to be generated with suitable equipment using an SAE 40 monograde mineral oil or equivalent and supplied to a test chamber. The selection of the oil to be used is to take into consideration risks to health and safety, and the appropriate controls implemented. A low toxicity, low flammability oil of similar viscosity may be used as an alternative. The oil mist produced is to have an average (or arithmetic mean) droplet size not exceeding 5 μm. The oil droplet size is to be checked using the sedimentation method or an equivalent method to a relevant international or national standard. If the sedimentation method is chosen, the test chamber is to have a minimum height of 1m and volume of not less than 1 m^3.

Note: The calculated oil droplet size using the sedimentation method represents the average droplet size.

8.1.1.3 The oil mist concentrations used are to be ascertained by the gravimetric deterministic method or equivalent. Where an alternative technique is used its equivalence is to be demonstrated.

Note: For this test, the gravimetric deterministic method is a process where the difference in weight of a 0.8 μm pore size membrane filter is ascertained from weighing the filter before and after drawing 1 litre of oil mist through the filter from the oil mist test chamber. The oil mist chamber is to be fitted with a recirculating fan.

8.1.1.4 Samples of oil mist are to be taken at regular intervals and the results plotted against the oil mist detector output. The oil mist detector is to be located adjacent to where the oil mist samples are drawn off.

8.1.1.5 The results of a gravimetric analysis are considered invalid and are to be rejected if the resultant calibration curve has an increasing gradient with respect to the oil mist detection reading. This situation occurs when insufficient time has been allowed for the oil mist to become homogeneous. Single results that are more than 10% below the calibration curve are to be rejected. This situation occurs when the integrity of the filter unit has been compromised and not all of the oil is collected on the filter paper.

8.1.1.6 The filters require to be weighed to a precision of 0.1 mg and the volume of air/oil mist sampled to 10 m*l*.

8.1.2 For type approval by ISC, the testing is to be witnessed by the Surveyor or authorised personnel from ISC.

8.1.3 Oil mist detection equipment is to be tested in the orientation (vertical, horizontal or inclined) in which it is intended to be installed on an engine or gear case as specified by the equipment manufacturer.

8.1.4 Type testing is to be carried out for each type of oil mist detection and alarm equipment for which a manufacturer seeks classification approval. Where sensitivity levels can be adjusted, testing is to be carried out at the extreme and mid-point level settings.

9 *Assessment*

9.1 Assessment of oil mist detection equipment after testing is to address the requirements specified in 9.1.1 to 9.1.3.

9.1.1 The equipment to be tested is to have evidence of design appraisal/approval by ISC witnessing tests.

9.1.2 Details of the detection equipment to be tested are to be recorded such as name of manufacturer, type designation, oil mist concentration assessment capability and alarm settings, and the maximum percentage level of lens obscuration.

9.1.3 After completing the tests, the detection equipment is to be examined and the condition of all components ascertained and documented. Photographic records of the monitoring equipment condition are to be taken and included in the report.

10 *Design series qualification*

10.1 The approval of one type of detection equipment may be used to qualify other devices having identical construction details. An application and related information are to be submitted for confirmation.

11 *The report*

11.1 The test house is to provide a full report which includes the information specified in 11.1.1 to 11.1.3.

11.1.1 Test specification.

11.1.2 Details of equipment tested.

11.1.3 Results of tests, including a declaration by the manufacturer of the oil mist detector of its performance, accuracy and precision of oil mist concentration in air, range, resolution, response time, sensitivity, obscuration of sensor detection, declared as percentage of obscuration (0% totally clean, 100% totally obscure) and detector failure alarm.

12 *Acceptance*

12.1 Acceptance of crankcase oil mist detection equipment is at the discretion of ISC based on the

appraisal plans and particulars and the test house report of the results of type testing.

12.2 The plans and information specified in 12.2.1 to 12.2.4 are to be submitted for acceptance of oil mist detection equipment and alarm arrangements:

12.2.1 Description of oil mist detection equipment and system including alarms.

12.2.2 Copy of the test house report identified in 11.1 of this Appendix.

12.2.3 Schematic layout of engine oil mist detection arrangements showing location of detectors/sensors and piping arrangements and dimensions.

12.2.4 Maintenance and test manual which is to include the following information:

(1) intended use of equipment and its operation;

(2) functionality tests to demonstrate that the equipment is operational and that any faults can be identified and corrective actions notified;

(3) maintenance routines and spare parts recommendations;

(4) limit setting and instructions for safe limit levels;

(5) where necessary, details of configurations in which the equipment is and is not to be used.

Appendix 9 TYPE TESTING PROCEDURE OF EXPLOSION RELIEF DEVICES FOR COMBUSTION AIR INLET AND EXHAUST GAS MANIFOLDS OF I.C. ENGINES USING GAS AS FUEL

1 *Scope*

1.1 This Appendix specifies testing procedure for explosion relief devices for combustion air inlet manifold and exhaust gas manifold of internal combustion engines using gas as fuel.

2 *Definitions*

2.1 Definitions addressing gas as fuel as given in Appendix 1 Safety of Low Pressure Gas Fuel Engines of this Chapter, apply.

2.2 Explosion relief device (ERD) means a device to protect a component against a determined overpressure in the event of a gas explosion. The device is fitted with a flame arrester and may be a valve, a rupture disc or other, as applicable.

3 *Documents*

3.1 Prior to testing, the following documentation for the ERD shall be submitted for approval:

(1) drawings (sectional drawings, details, assembly etc.);

(2) specification data sheet including operating conditions and design limits such as:

① maximum permissible operating pressure, resulting from maximum charging air or exhaust gas back pressure;

② maximum permissible operating temperature, resulting from maximum charging air or exhaust gas temperature;

③ static opening pressure, resulting from maximum charging air or exhaust gas back pressure;

④ maximum explosion pressure, i.e. maximum pressure that the device can withstand;

⑤ geometric relief area;

(3) product marking;

(4) installation and operation manual;

(5) test program;

(6) specification of test vessel.

4 *Tests*

4.1 Test specimens

4.1.1 The ERD used for the explosion test is to be selected from the manufacturer's production line by ISC:

(1) as a finished certified component itself, or

(2) on samples taken from earlier stages in the production of the component, when applicable.

4.1.2 If necessary, an additional ERD may need to be selected for the demonstration of the opening pressure. The selected ERD has to be clearly marked.

4.1.3 If applicable, the selected ERD shall be representative for the type range and operating conditions, for example:

(1) kind of ERD (valve, rupture disc, etc.);

(2) mounting orientation (vertical, horizontal);

(3) design of ERD (e.g., spring design, sealing);

(4) design of flame arrester;

(5) ERD intended to be fitted to the air inlet or exhaust gas manifold of an engine having a turbocharger with characteristics as per the testing conditions in 4.3.2 of this Appendix.

4.1.4 The selection of the representative ERD is subject to approval by the ISC.

4.2 Demonstration of opening pressure

The ERD which has been selected is to be subjected to a pressure test at the manufacturer's works to demonstrate that the static opening pressure is kept within the manufacturer's specification and that the

ERD is air tight at the maximum permissible operating pressure for at least 30 seconds.

4.3 Explosion test

4.3.1 Test facility

4.3.1.1 The test facilities are to be accredited to a national or international standard, e.g. ISO/IEC 17025, and are to be acceptable to the ISC.

4.3.1.2 The test facilities are to be equipped so that they can perform and record explosion testing in accordance with this procedure.

4.3.1.3 The test facilities are to have equipment for controlling and measuring a methane gas concentration within a test vessel to an accuracy of ±0.1%.

4.3.1.4 The test facilities are to be capable of effective point-located ignition of a methane/air mixture.

4.3.1.5 The test facility arrangements are to be capable of measuring and recording the pressure changes throughout an explosion test at a frequency recognizing the speed of the events during an explosion (10 kHz or above).

4.3.1.6 The explosion test (Para 4.3.5 of this Appendix) is to be documented by high speed (250 frames/s or above) video recording. The video recording shall be provided with a time stamp.

4.3.2 Test vessel

4.3.2.1 The test vessel is a simplified model of the air inlet or exhaust gas manifold. The free area of the connected turbo charger (compressor or turbine wheel) is to be considered.

4.3.2.2 The test vessel shall comply with the following requirements:

(1) The shape of the test vessel is to correspond to a pipe with $L/D \geq 10$.

(2) The test vessel is to be equipped with a rupture disc at one front end to simulate the turbo charger. The relief area of the rupture disc shall be in relationship to the test vessel diameter based on turbocharger manufacturer data for an equivalent free area of compressor or turbine wheel. The opening pressure shall be ± 10% of the static opening pressure of the ERD.

(3) The volume of the test vessel is to comply with the specific relief area of the ERD of 700 cm^2/m^3 ± 15%.

(4) The test vessel is to be provided with all necessary flanges and connection to mount the ERD in the intended position, to mount a rupture disc as turbo charger simulation, to connect the Methane-air mixture supply and the measurement equipment.

(5) The ignition is to be made at the middle of the test vessel.

(6) The test vessel is to be designed to verify a homogeneous air / methane mixture inside the vessel.

(7) The test vessel is to have connections for measuring the pressure in the test vessel in at least two positions, one at the ERD and the other at the test vessel center.

(8) The test vessel is to have a design pressure of not less than the maximum explosion pressure of a stoichiometric air / methane mixture at test conditions in Para 4.3.6 of this Appendix.

(9) The test vessel configuration is subject to approval by ISC.

4.3.2.3 Typical test vessel configurations:

As shown in Figures 4.3.2.3(1) to 4.3.2.3(3), all test vessel configurations to be equipped with a rupture disc (1) (turbo charger simulation) at one front end. The ignition is in the centre of the test vessel (↯). The pressure sensors are mounted at the valve flanges (p1) and at the test vessel centre (p2). The measuring of the methane concentration to verify a homogeneous air / methane mixture can be performed at both ends of the test vessel, e.g. (c1) and (c2).

Figure 4.3.2.3(1) Configuration without ERD (flanges for ERDs closed (2))

Figure 4.3.2.3(2) Configuration with ERD (3) mounted at the front end of the test vessel

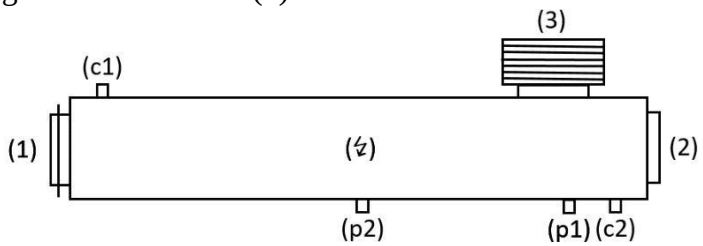

Figure 4.3.2.3(3) Configuration with ERD (3) mounted on top of the test vessel

4.3.3 Explosion test process

4.3.3.1 The explosion testing is to be performed in two stages according to 4.3.4 and 4.3.5 of this Appendix for each ERD that is required to be approved as type tested.

4.3.3.2 The explosion testing is to be witnessed by a Society surveyor.

4.3.3.3 Calibration records for the instrumentation used to collect data are to be presented to, and reviewed by, the attending surveyor.

4.3.4 Reference test – Explosion test without ERD

4.3.4.1 Two explosion tests are to be carried out in the test vessel without ERD. The test vessel configuration is shown in Figure 4.3.2.3(1) of this Appendix.

4.3.4.2 The aim of this test is to establish a reference pressure level in the test vessel which can be used for determination of the capability of a relief valve in terms of pressure relief.

4.3.5 ERD test – Explosion test with ERD

4.3.5.1 Two explosion tests are to be carried out in the test vessel with the same ERD at the required position. If the ERD is a rupture disc with flame arrester, the rupture disc shall be replaced.

4.3.5.2 If shielding arrangements to deflect the emission of explosion combustion products at the ERD are intended, the ERD are to be tested with the shielding arrangements fitted. The test vessel configuration is shown in Figure 4.3.2.3(2) or 4.3.2.3(3).

4.3.6 Explosion test method

4.3.6.1 The test conditions shall comply with the intended use of the ERD, such as:

(1) pipe diameter;

(2) operating pressure;

(3) operating temperature;

(4) installation orientation.

4.3.6.2 All explosion tests are to be carried out using an air and methane mixture with a volumetric methane concentration of 9.5% ± 0.5%. A homogeneous air / methane mixture inside the test vessel is to be verified. The concentration of methane shall not differ by more than 0.5%.

4.3.6.3 The initial pressure in the test vessel is to be the specified maximum operating pressure of the ERD.

4.3.6.4 The initial temperature in the test vessel is to be the specified maximum operating temperature of the ERD.

4.3.6.5 If the initial pressure and/or initial temperature deviate from the design limits, the ERD manufacturer shall prove the acceptability of this deviation either using standards or generally applicable calculation methods.

4.3.6.6 The ignition is to be made using an explosive charge of 50 - 100 Joule.

4.3.6.7 Successive explosion testing to establish an ERD functionality is to be carried out as quickly as possible during stable weather conditions.

4.3.6.8 The pressure rise and decay during all explosion testing is to be recorded.

4.3.6.9 The effect of an ERD in terms of pressure relief following an explosion is ascertained from maximum pressure recorded at the centre of the test vessel during the two stages. The pressure relief within the test vessel due to the installation of an ERD is the difference between average pressure of the two explosions of the reference test (4.3.4 of this Appendix) and the average of the two explosions of the ERD test (4.3.5 of this Appendix).

4.3.6.10 For acceptance of correct functioning of the flame arrester, there is to be no indication of flame or combustion outside of the ERD during its testing (4.3.5 of this Appendix). This is to be monitored by a high-speed video camera (4.3.1 of this Appendix), for which ambient light conditions are to be considered to maximise the potential for flame/combustion detection. The use of a dark, ideally matt finish, background and an avoidance of direct light onto the video camera monitored area are recommended.

4.3.6.11 After each ERD test (4.3.5 of this Appendix), the external condition of the flame arrester to be

examined for signs of damage and/or deformation that may affect the operation of the ERD.

4.4 Check of ERD components

4.4.1 After completing the explosion tests, the ERDs are to be dismantled and the condition of all components are to be ascertained and documented.

5 *Test report*

5.1 A complete test report has to be submitted to ISC for:
(1) the demonstration of opening pressure (4.2 of this Appendix);
(2) the explosion test (4.3 of this Appendix).
5.2 The reports shall include respective information according to the requirements in 4 of this Appendix, as applicable:
(1) test specimens;
(2) test facility, including measuring equipment and test vessel;
(3) measuring results (pressures, temperatures, flame velocities, volumetric methane concentration, ambient conditions etc.);
(4) video documentation of explosion tests;
(5) photo documentation of ERD components.

6 *Assessment*

6.1 To verify compliance with this requirement the assessment has to address the following:
6.1.1 Function and mechanical integrity of the ERD.
(1) After dismantling of the ERD, the flame arrester shall not show signs of damage or any deformation that may affect the operation of the ERD.
(2) If a valve is used any indication of valve sticking or uneven opening during the explosion that may affect subsequent operation of the valve has to be considered.
(3) The mechanical integrity of the ERD is proven up to a maximum explosion pressure (as average of the two explosions) of the ERD tests in 4.3.5 of this Appendix.
6.1.2 The functioning of the flame arresters is considered satisfactory if there is no indication of flame or combustion outside the ERD during the explosion tests.

7 *Approval*

7.1 The approval of an ERD is at the discretion of individual classification societies based on the appraisal of plans and particulars and the test report of type testing.
7.2 The type approval is valid only for an ERD fitted to the air inlet or exhaust gas manifold of an engine having a turbocharger with compressor or turbine wheel characteristics corresponding to those required in 4.3.2 of this Appendix for the test vessel rupture disc in terms of free area.

Appendix 10 SAFETY OF METHANOL/ETHANOL FUEL ENGINES

1 *General Requirements*

1.1 Application and scope

1.1.1 This Appendix applies to engines supplied with methanol/ethanol as fuel. This Appendix only specifies relevant requirements for the use of methanol/ethanol fuel, and in addition, methanol/ethanol fuel engines are to comply with relevant provisions of this Chapter.

1.1.2 Methanol/ethanol fuel engines can be either dual fuel engines or methanol/ethanol fuel only engines. Methanol/ethanol fuel can be introduced as follows:

(1) cylinder air inlet channel port; or

(2) cylinder direct injection.

The methanol/ethanol and air mixture in the cylinder can be ignited by the combustion of a certain amount of fuel (pilot injection) or by extraneous ignition (sparking plug).

1.1.3 This Appendix covers the following applications, but is not limited to:

(1) mechanical propulsion;

(2) generating sets intended for main propulsion and auxiliary applications;

(3) single engine or multi-engine installations.

1.1.4 For fuel only engines, applicable requirements of this Appendix can be determined in consultation with ISC.

1.2 *Definitions*

(1) Dual fuel engine means an engine that can burn methanol/ethanol as fuel simultaneously with liquid diesel fuel, either as pilot oil or bigger amount of liquid diesel fuel (methanol/ethanol mode), and also has the capability of running on liquid diesel fuel oil only (Diesel mode).

(2) Fuel only engine means an engine capable of operating on methanol/ethanol fuel only and not able to switch over to oil fuel operation.

(3) Methanol/ethanol fuel engine means either a methanol/ethanol fuel only engine or a dual fuel engine.

(4) Pilot fuel means the fuel oil that is injected into the cylinder to ignite the methanol/ethanol and air mixture on dual fuel engines.

(5) Methanol/ethanol fuel valve unit is a set of valves and fittings used to control the methanol/ethanol fuel supply to each engine, which is used to control or adjust the methanol/ethanol fuel supply before the engine.

(6) Recognized standards mean applicable international or national standards acceptable to ISC or standards laid down and maintained by an organisation which complies with the standards adopted by IMO and which are recognized by the Classification Society.

(7) Safety Concept is a document describing the safety philosophy with regard to methanol/ethanol as fuel. It describes how risks associated with this type of fuel are controlled under reasonably foreseeable abnormal conditions as well as possible failure scenarios and their control measures.

Note: A detailed evaluation regarding the hazard potential of injury from a possible explosion is to be carried out and reflected in the safety concept of the engine.

1.3 *Plans and documents*

1.3.1 The following plans and documents are to be submitted for approval with regard to the approval of gas fuel engines, in addition to those required in 9.1.12.1 of this Chapter :

No.	Plans and documents
(1)	Schematic layout or other equivalent documents of methanol/ethanol fuel system on the engine
(2)	Methanol/ethanol piping system (including double-walled arrangement where applicable)
(3)	Parts for methanol/ethanol admission system②
(4)	Arrangement of explosion relief valves (crankcase①, charge air manifold, exhaust gas manifold) as applicable
(5)	List of certified safe equipment and evidence of relevant certification
(6)	Schematic layout or other equivalent documents of fuel oil system (main and pilot fuel systems) on the engine (only for dual fuel engine)
(7)	Shielding of high pressure fuel pipes for pilot fuel system, assembly (only for dual fuel engine)
(8)	High pressure parts for pilot fuel oil injection system②(only for dual fuel engine)
(9)	Ignition system (only for fuel only engine)

Note:
① If required by 9.1.12 of this Chapter.
② The documentation to contain specification of pressures, pipe dimensions and materials.

1.3.2 The following plans and documents are to be submitted for information with regard to the approval of methanol/ethanol fuel engines, in addition to those required in 9.1.12.2 of this Chapter:

No.	Plans and documents
(1)	Safety concept
(2)	Report of the risk analysis①
(3)	Methanol/ethanol specification
(4)	Other plans and documents as deemed necessary by ISC

Note:
① see 1.4 of this Appendix.

1.4 *Risk analysis*

1.4.1 The risk analysis is to address:

(1) a failure or malfunction of any system or component involved in the methanol/ethanol operation of the engine;

(2) a fuel leakage downstream of the methanol/ethanol valve unit;

(3) the safety of the engine in case of emergency shutdown or blackout, when running on methanol/ethanol;

(4) the inter-actions between the methanol/ethanol fuel system and the engine.

Note: With regard to the scope of the risk analysis it shall be noted that failures in systems external to the engine, such as fuel storage or fuel gas supply systems, may require action from the engine control and monitoring system in the event of an alarm or fault condition. Conversely failures in these external systems may, from the vessel perspective, require additional safety actions from those required by the engine limited risk analysis.

1.4.2 The risk analysis is to be carried out in accordance with international standard ISO 31010: Risk management - Risk assessment techniques, or other recognized standards.

The required analysis is to be based on the single failure concept, which means that only one failure needs to be considered at the same time. Both detectable and non-detectable failures are to be considered. Consequences failures, i.e. failures of any component directly caused by a single failure of another component, are also to be considered.

1.4.3 The risk analysis is to:

(1) Identify all the possible failures in the concerned equipment and systems which could lead:

① to the presence of methanol/ethanol in components or locations not designed for such purpose, and/or

② to ignition, fire or explosion.

(2) Evaluate the consequences.

(3) Where necessary, identify the failure detection method.

(4) Where the risk cannot be eliminated, identify the corrective measures, e.g. in the system design such as redundancies or safety devices, monitoring or alarm provisions which permit restricted operation of the system; in the system operation, such as initiation of the redundancy or activation of an alternative mode of operation.

The results of the risk analysis are to be documented.

1.4.4 The risk analysis required for engines is to cover at least the following equipment and systems:

(1) failure of the methanol/ethanol-related systems or components, in particular methanol/ethanol piping and cylinder methanol/ethanol supply valves etc. Failures of the methanol/ethanol supply components not located directly on the engine, are not to be considered in the analysis;

(2) failure of the ignition system (oil fuel pilot injection or sparking plugs);

(3) failure of the methanol/ethanol combustion or abnormal combustion (misfiring, knocking);

(4) failure of the engine monitoring, control and safety systems;

Note: Where engines incorporate electronic control systems, a failure mode and effects analysis (FMEA) is to be carried out in accordance with 9.1.12.2(23) and Note 5 of this Chapter.

(5) changes of operating modes for dual fuel engines, including fuel oil mode, methanol/ethanol fuel mode and other working mode;

(6) hazard potential for crankcase methanol/ethanol fuel accumulation, for engines where the space below the piston is in direct communication with the crankcase.

2 *Design Requirements*

2.1 General principles

2.1.1 The manufacturer is to declare the methanol/ethanol fuel for the engine.

2.1.2 Components containing or likely to contain methanol/ethanol are to be designed to:

(1) minimise the risk of fire and explosion so as to demonstrate an appropriate level of safety commensurate with that of an oil-fuelled engine;

(2) mitigate the consequences of a possible explosion to a level providing a tolerable degree of residual risk, due to the strength of the component(s) to withstand the overpressure due to the ignition of leaked methanol/ethanol in the most severe condition or the fitting of suitable pressure relief devices of an approved type.

Note:

① Discharge from pressure relief devices is to prevent the passage of flame to the machinery space and be arranged such that the discharge does not endanger personnel or damage other engine components or systems.

② Relief devices are to be fitted with a flame arrester.

2.2 *Design requirements*

2.2.1 A means is to be provided to monitor and detect poor combustion or misfiring in the engine. In the event that it is detected, continued operation may be allowed, provided that the fuel supply to the concerned cylinder is shut off and provided that the operation of the engine with one cylinder cut-off is acceptable with respect to torsional vibrations.

Engine components through which methanol/ethanol fuel may flow are to be effectively sealed to prevent leakage of fuel into the machinery space.

2.2.2 Engine-mounted methanol/ethanol pipes are to be designed in accordance with the methanol/ethanol pipe requirements (e.g. wall thickness, allowable stress, material, pipe manufacture and connection etc.) in Chapter 3 of ISC Guidelines for Ships Using Methanol/Ethanol Fuel and the arrangement is to satisfy the following requirements:

(1) Pipes and equipment containing methanol/ethanol fuel are defined as hazardous area Zone 0. The space between the methanol/ethanol fuel piping and the wall of the outer pipe or duct is defined as hazardous area Zone 1.

(2) Methanol/ethanol fuel fuel piping is to be arranged for gas freeing and purging.

(3) The arrangement and installation of methanol/ethanol fuel piping are to provide the necessary flexibility to accommodate the sway or vibration of the engine and prevent fatigue damage at the connection between the piping and the engine.

2.2.3 Charge air system on the engine

(1) The charge air system on the engine is to be designed in accordance with 2.1.2 above.

(2) In case of a single engine installation, the engine is to be capable of operating at sufficient load to maintain power to essential consumers after opening of the pressure relief devices caused by an explosion event. Sufficient power for propulsion capability is to be maintained.

Note: Load reduction is to be considered on a case by case basis, depending on engine configuration (single or multiple) and relief mechanism (self-closing valve or bursting disk).

2.2.4 Exhaust system on the engine

(1) The exhaust gas system on the engine is to be designed in accordance with 2.1.2 above.

(2) In case of a single engine installation, the engine is to be capable of operating at sufficient load to maintain power to essential consumers after opening of the pressure relief devices caused by an explosion event. Sufficient power for propulsion capability is to be maintained.

(3) Each methanol/ethanol engine is to be provided with independent exhaust system.

2.2.5 For engines where the space below the piston is in direct communication with the crankcase, protection of crankcase is also to comply with the following requirements:

(1) Detailed assessment is to be carried out to hazard potential for crankcase gas accumulation.

(2) For maintenance purposes, a connection, or other means, are to be provided for crankcase inerting and ventilating and gas concentration measuring.

2.2.6 Control, monitoring, alarm and safety systems

(1) The engine control system is to be independent and separate from the safety system.

(2) The methanol/ethanol supply valves are to be controlled by the engine control system or by the engine methanol/ethanol demand.

(3) Combustion is to be monitored on an individual cylinder basis.

(4) If monitoring of combustion for each individual cylinder is not practicable due to engine size and design, common combustion monitoring may be accepted.

(5) Unless the risk analysis required by 1.4 of this Appendix proves otherwise, the monitoring and safety system functions for dual fuel or fuel only engines are to be provided in accordance with Table 1 of this Appendix in addition to the general monitoring and safety system functions given by the Rules.

Note: For dual fuel engines, Table 1 applies only to the methanol/ethanol mode.

Monitoring and Safety System Functions for Methanol/Ethanol Fuel Engines

Table 1

Parameter	Alarm	Automatic activation of the engine block valve	Automatic switching over to oil fuel mode①	Engine shutdown
Abnormal pressures in the methanol/ethanol fuel supply line	×	×	×	× ⑤
Methanol/ethanol fuel supply systems - malfunction	×	×	×	× ⑤
Pilot fuel injection or spark ignition systems - malfunction	×	× ②	×	× ②⑤
Exhaust gas temperature after each cylinder - high	×	× ②	×	×②⑤
Exhaust gas temperature after each cylinder, deviation from average – low③	×	× ②	×	× ②⑤
Cylinder pressure or ignition - failure, including misfiring, knocking and unstable combustion	×	× ②④	× ④	× ②④⑤
Oil mist concentration in crankcase or bearing temperature⑥ - high	×	×		×
Pressure in the crankcase – high ④ (for engines where the space below the piston is in direct communication with the crankcase)	×	×	×	
Engine stops - any cause	×	×		
Failure of the control-actuating medium of the methanol/ethanol fuel block valve	×	×	×	

Symbol: × Applicable

Note:

① Dual fuel engine only, when running in methanol/ethanol mode.

② For fuel only engines, the block valve and the engine shutdown may not be activated in case of specific failures affecting only one cylinder, provided that the concerned cylinder can be individually shutoff and the safe operation of the engine in such conditions is demonstrated by the risk analysis.

③ Required only if necessary for the detection of misfiring.

④ In the case where the failure can be corrected by an automatic mitigation action, only the alarm may be activated. If the failure persists after a given time, the safety actions are to be activated.

⑤ Fuel only engine only.

⑥ Where required by 9.7.6 of this Chapter.

3 Specific Design Requirements

3.1 Dual fuel engines

3.1.1 The maximum continuous power that a dual fuel engine can develop in methanol/ethanol mode may be lower than the approved MCR of the engine (i.e. in oil fuel mode), depending in particular on the methanol/ethanol quality. This maximum power available in methanol/ethanol mode and the corresponding conditions are to be stated by the engine manufacturer and demonstrated during the type test. The 110% load tests are not required in the methanol/ethanol mode of dual fuel engines when 4.1.4, 4.2.1 and 4.3 of this Appendix are implemented in accordance with the provisions in 1.3 of Appendix 4, 2.3 and 3.4 of Appendix 6 of this Chapter.

3.1.2 Dual fuel engines are to be arranged to use either oil fuel or methanol/ethanol fuel for the main fuel charge and with pilot oil fuel for ignition. The engines are to be arranged for rapid changeover from methanol/ethanol use to fuel oil use. In the case of changeover to either fuel supply, the engines are to be capable of continuous operation using the alternative fuel supply without interruption to the power supply. Changeover to methanol/ethanol fuel operation is to be only possible at a power level and under conditions where it can be done with acceptable reliability and safety as demonstrated through testing.

Changeover from methanol/ethanol fuel operation mode to oil fuel operation mode is to be possible at all situations and power levels.

The changeover process itself from and to methanol/ethanol operation is to be automatic but manual interruption is to be possible in all cases.

In case of shut-off of the methanol/ethanol supply, the engines are to be capable of continuous operation by oil fuel only.

3.1.3 Methanol/ethanol supply to the combustion chamber is not to be possible without operation of the pilot oil injection.

Note: Pilot injection is to be monitored for example by fuel oil pressure and combustion parameters.

3.1.4 In case of an emergency stop or a normal stop, the methanol/ethanol fuel is to be automatically shut off not later than the ignition source. It is not to be possible to shut off the ignition source without first or simultaneously closing the fuel supply to each cylinder or to the complete engine.

3.2 *Fuel only engines*

3.2.1 In case of ignition failure of the ignition system, the engine is to be shut down except if this failure is limited to one cylinder, subject to immediate shut off of the cylinder methanol/ethanol supply and provided that the safe operation of the engine is substantiated by the risk analysis and by tests.

3.2.2 In case of an emergency stop or a normal stop, the methanol/ethanol fuel is to be automatically shut off not later than the ignition source. It is not to be possible to shut off the ignition source without first or simultaneously closing the fuel supply to each cylinder or to the complete engine.

4 *Type Testing, Factory Acceptance Tests and Shipboard Trials*

4.1 Type Testing

4.1.1 Type approval of dual fuel and fuel only engines is to be carried out in accordance with 9.10.1 and 9.10.2 of this Chapter, taking into account the additional requirements below.

4.1.2 In addition to the criteria given in 9.1.2.1(1) of this Chapter, the type of engine is defined by the following:

(1) methanol/ethanol admission method (direct cylinder injection, cylinder intake channel injection etc.);

(2) methanol/ethanol supply valve operation (mechanical or electronically controlled);

(3) ignition system (pilot injection, spark ignition etc.);

(4) ignition system (mechanical or electronically controlled).

4.1.3 In addition to the safety precautions mentioned in 1.2, Appendix 4 of this Chapter, measures to verify that methanol/ethanol fuel piping on engine is gas tight and liquid tight are to be carried out prior to start-up of the engine.

4.1.4 The type testing of the engine is to be carried out in accordance with 1.3, Appendix 4 of this Chapter. For dual fuel engines, the load tests are to be carried out in methanol/ethanol mode at the different percentages of the maximum power available in methanol/ethanol mode (see 3.1.1 of this Appendix).

4.1.5 In addition to the measurements and records required in 1.4, Appendix 4 of this Chapter, the following engine data are to be measured and recorded:

(1) Each fuel index for methanol/ethanol and diesel as applicable (or equivalent reading).

(2) Methanol/ethanol pressure and temperature at the inlet of the methanol/ethanol manifold.

Additional measurements may be required in connection with the design assessment.

4.1.6 In addition to internal tests required in 2.1, Appendix 4 of this Chapter, the following conditions are to be tested:

(1) dual fuel engines are to run the load points in both methanol/ethanol and diesel modes (with and without pilot injection in service) as found applicable for the engine type.

(2) for dual fuel engines, switch over between methanol/ethanol and diesel modes are to be tested at different loads.

4.1.7 Witnessed tests are to be carried out in accordance with 2.2, Appendix 4 of this Chapter. The following requirements are to be considered:

(1) The following test conditions are to be considered for dual fuel engine during the load test:

① All load points must be run in both methanol/ethanol and diesel modes that apply for the engine type as defined by the engine designer. This also applies to the overspeed test.

(2) The following items are to be carried out for functional test:

① For dual fuel engines, the lowest specified speed is to be verified in diesel mode and methanol/ethanol mode.

② For dual fuel engines, switch over between methanol/ethanol and diesel modes are to be tested at different loads.

③ The efficiency of the ventilation arrangement of the double walled piping system is to be verified.

④ Simulation of a methanol/ethanol leakage in way of a cylinder methanol/ethanol supply valve.

Engines intended to produce electrical power are to be tested as follows:

① Capability to take sudden load and loss of load in accordance with the provisions of 9.7.10.1 of this Chapter.

Notes:

1. For dual fuel engines, switchover to oil fuel during the test is acceptable.

2. Application of electrical load in more than 2 load steps can be permitted in the conditions stated in 9.7.10.1 of this Chapter.

(3) Fuel only and dual fuel engines are to undergo integration tests to verify that the response of the complete mechanical, hydraulic and electronic engine system is as predicted for all intended operational modes. The scope of these tests is to be agreed with ISC for selected cases based on the risk analysis, and is at least to include the following incidents:

① Failure of ignition (spark ignition or pilot injection systems), both for one cylinder unit and common system failure;

② Failure of a cylinder methanol/ethanol supply valve;

③ Failure of the combustion (to be detected by e.g. misfiring, knocking, exhaust temperature deviation, etc.);

④ Abnormal methanol/ethanol pressure;

⑤ Abnormal methanol/ethanol temperature*.

Note*: This test may be carried out using a simulation signal of the temperature.

4.1.8 Component inspection is to be carried out in accordance with the provisions of 2.3, Appendix 4 of this Chapter. The components to be inspected after the test run are to include also:

(1) methanol/ethanol supply valve;

(2) pilot fuel injection valve/spark igniter.

4.2 *Factory acceptance test*

4.2.1 Factory acceptance tests are to be carried out in accordance with Appendix 6 of this Chapter, taking into account the additional requirements below.

For dual fuel engines, the load tests referred to in 2.3, Appendix 6 of this Chapter are to be carried out in methanol/ethanol mode at the different percentages of the maximum power available in methanol/ethanol mode (see 3.1.1 of this Appendix).

4.2.2 In addition to the safety precautions mentioned in 1.1, Appendix 6 of this Chapter , measures to verify that methanol/ethanol fuel piping on engine is gas tight and liquid tight are to be carried out prior to start-up of the engine.

4.2.3 In addition to the records required in 2.2, Appendix 6 of this Chapter, the following engine data are to be recorded:

(1) Fuel index, both methanol/ethanol and diesel as applicable (or equivalent reading);

(2) Methanol/ethanol pressure and temperature at the inlet of the methanol/ethanol manifold.

4.2.4 Test loads for various engine applications are given in 2.3, Appendix 6 of this Chapter. Dual fuel engines are to be tested in both diesel and methanol/ethanol pressure and temperature at the inlet of the methanol/ethanol manifold mode as found applicable. In addition the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

4.2.5 Methanol/ethanol fuel engines are to undergo integration tests to verify that the response of the complete mechanical, hydraulic and electronic engine system is as predicted for all intended operational modes.

The scope of these tests is to be agreed with ISC for selected cases based on the risk analysis, and is at least to include the following incidents:

① Failure of ignition (spark ignition or pilot injection systems), both for one cylinder unit and common system failure;

② Failure of a cylinder methanol/ethanol supply valve;

③ Failure of the combustion (to be detected by e.g. misfiring, knocking, exhaust temperature deviation, etc.);

④ Abnormal methanol/ethanol pressure;

⑤ Abnormal methanol/ethanol temperature.

Note: The above tests may be carried out using simulation or other alternative methods, subject to special consideration by ISC.

4.3 *Shipboard trials*

4.3.1 Shipboard trials are to be carried out in accordance with the provisions of Appendix 6 of this Chapter. For dual fuel engines, the test loads are to be carried out in all operating modes (methanol/ethanol mode, diesel mode, etc.). For dual fuel engines, when load tests specified in 3.4, Appendix 6 of this Chapter are carried out in methanol/ethanol mode, test loads are taken as each percentage of the maximum output power in methanol/ethanol mode (see 3.1.1 of this Appendix).

CHAPTER 10 TRANSMISSION GEARING

Section 1 GENERAL PROVISIONS

10.1.1 General requirements

10.1.1.1 The requirements of this Chapter are applicable to transmission gearing for main propulsion machinery and driving auxiliary machinery where the transmitted power is equal to or more than 100 kW.

10.1.1.2 The certification requirements and inspection of products for transmission gearing are to comply with the relevant requirements in Chapter 3, PART ONE of the Rules.

10.1.2 *Strengthening for navigation in ice*

10.1.2.1 In the case of ships strengthened in ice, the transmission gearing of main propulsion systems is to comply with the relevant requirements in Chapter 14 of this PART.

10.1.3 *Vibration and alignment*

10.1.3.1 For the requirements for vibration and alignment of the transmission gearing, see Chapter 12 of this PART.

10.1.4 *Plans and documents*

10.1.4.1 Following plans and documents are to be submitted for approval:

(1) General arrangement (longitudinal and transverse sections);

(2) Details of pinions and wheels, including ring gear, where applicable, and parameters necessary for calculation of load capacity;

(3) Gear shafts;

(4) Bosses, if any;

(5) Clutches and/or couplings;

(6) Other power transmitting parts;

(7) Gear casing, incl. propeller thrust bearing housing, if any;

(8) Basic sizes of the tooth profile of the tools;

(9) Calculations of the load capacity of gears;

(10) Strength calculations of shafts;

(11) Strength calculations of clutches and/or couplings;

(12) Calculation of combined dynamic reaction forces and its acting direction of sliding bearings for gearboxes;

(13) Details of heat treatment of gears;

(14) Details of gear materials;

(15) Details of weld procedures for gears or gearbox, if any;

(16) Plans and documents for gear box lubricating and cooling systems;

(17) Diagram of the hydraulic system, if applicable;

(18) Other plans and documents deemed necessary by ISC.

Section 2 MATERIALS

10.2.1 *Material properties*

10.2.1.1 Shafts, gear, wheel's rim, if any, couplings, etc. of the transmission gearing are to be made of steel forgings, and the materials for forgings are to be in accordance with the relevant requirements of ISC Rules for Materials and Welding.

10.2.1.2 For gears of through-hardened steels, provision is to be made for a hardness differential between pinion teeth and wheel teeth. For this purpose, the specified tensile strength of the wheel material is not to be more than 85% of that of the pinion.

10.2.1.3 The full specified minimum tensile strength of the core is to be 800 N/mm^2 for induction-hardened or nitrided gearing and 750 N/mm^2 for carburized gearing.

10.2.1.4 Where it is proposed to use alloy steel forgings, the chemical composition and mechanical properties are to comply with relevant requirements of ISC Rules for Materials and Welding.

10.2.2 *Non-destructive tests*

10.2.2.1 An ultrasonic examination is to be carried out on all gear blanks where the finished diameter of the surfaces, where teeth will be cut, is in excess of 200 mm.

10.2.2.2 Magnetic particle or liquid penetrant examination is to be carried out on all surface-hardened teeth. This examination may also be requested on the finished machined teeth of through-hardened gears.

Section 3 DESIGN AND CONSTRUCTION

10.3.1 *Design*

10.3.1.1 Appraisal of gear strength is to comply with the requirements of "Appraisal of gear strength" in Appendix 1 of this Chapter. For the enclosed reduction transmission gearing used for main propulsion machinery where the maximum continuous transmitted power is less than 220 kW and for essential auxiliary machinery where the maximum continuous transmitted power is less than 110 kW, the calculation of load capacity of gears need not satisfy the requirements of this Chapter.

10.3.2 *Tooth form*

10.3.2.1 The roots of teeth are to be formed with smooth fillets of radius not less than 0.25 m_n.

10.3.2.2 Where the ratio of working length over the gear faces to reference diameter of pinion exceeds 1.5, the ends of the teeth are to be chamfered.

10.3.2.3 The teeth of pinions and wheels are to be suitably relieved on flanks in cases where any of the following conditions applies:

(1) normal module of teeth exceeds 6 mm;

(2) addendum of pinion teeth exceeds 65% of total working depth of engagement;

(3) ratio of total working depth of engagement to normal pitch of teeth exceeds 0.75.

10.3.3 *Tooth surface*

10.3.3.1 The hardened layer of the surface-hardened gear is to be distributed over and extended to the whole tooth surfaces and fillets.

10.3.3.2 For nitrided gear, generally, the depth of nitrided layer is not to be less than 0.40 mm.

10.3.3.3 For surface-hardened gears (except the nitrided) the depth of hardened layer is not to be less than 0.15 m_n.

10.3.3.4 For carburized gears, the surface hardness is generally not to be less than HRC 58.

10.3.4 *Gear*

10.3.4.1 The grade of accuracy of gear cutting is not to be less than 7 for diesel engines and 6 for turbines.

10.3.4.2 Where bolts or shrink-fit are used to secure the side plates to rim and boss of the wheels, the bolts are to be tight fit in holes and the nuts are to be suitably locked.

10.3.5 *Gear shafts*

10.3.5.1 The diameter d of the quill shafts is not to be less than the value obtained from the following formula:

$$d = 100 \sqrt[3]{\frac{400 N_e}{n_e R_m}} \quad \text{mm}$$

where: N_e — the maximum continuous output transmitted by the shaft, in kW;

n_e — speed of the shaft at N_e, in r/min;

R_m — minimum tensile strength of shaft material, in N/mm^2, but not exceeding 1,100 N/mm^2.

10.3.5.2 The diameter of gear shafts is to be calculated in accordance with 11.2.2 of this PART.

10.3.5.3 Where the gear is fitted on the gear shaft by key or shrink-fit, the diameter of gear shafts at the fitting area is to be increased by 5% over the value determined in 10.3.5.2.

10.3.5.4 Where the wheel shaft is driven by only one pinion or by two pinions arranged to subtend an angle at the centre of the shaft of less than 120°, the diameter of the wheel shaft between bearings is at least to be increased by 15% over the value determined by 10.3.5.2. Where it is driven by two pinions arranged to subtend an angle at the centre of the shaft of more than 120°, the diameter of the wheel shaft between bearings is at least to be increased by 10% over the value determined in 10.3.5.2.

10.3.6 *Gear casings*

10.3.6.1 Gear casings of welded construction are to be stress-relief heat treated on completion of welding

in accordance with the relevant requirements of ISC Rules for Materials and Welding.

10.3.6.2 Gear casings are to be of sufficient strength and rigidity, and are to be provided with inspection openings and adequate venting devices.

10.3.6.3 Where thrust bearing is provided inside the gear casing, the latter is to be adequately strengthened.

10.3.7 *Connections*

10.3.7.1 Where the coupling of the output shaft is fitted by means of the oil pressure injection method, the actual shrinkage allowance δ is to comply with the requirements of 11.3.2.3 of this PART; where shrink-fit is employed, 0.03 in the formula may be ignored.

10.3.7.2 For the shrink-fit of rim to boss, boss to shaft and the shrink-fit of other items, a safety factor against slippage in design is not to be less than $2.8C$, where C is a coefficient having the following values:

$C = 1$ for gears driven by turbines or electric motors and gears driven through a hydraulic, electromagnetic or high elasticity coupling;

$C =$ 1.2 in other cases.

10.3.7.3 Clutches and couplings in the transmission gearing are to comply with the requirements of Section 3, Chapter 11 of this PART.

10.3.8 *Grade of Meshing*

10.3.8.1 Tooth faces are to be evenly meshed. For diesel or turbine transmission gearing, the contact marking is not to be less than Grade 7 or Grade 6 respectively.

10.3.9 *Reversal*

10.3.9.1 For reversible gearing:

(1) the speed at free clutching and declutching is not to be less than 50% of the rated speed;

(2) the time required for reversal is not to be more than 15 s;

(3) sufficient astern power is to be available.

10.3.10 *Lubricating and cooling*

10.3.10.1 The construction and arrangement of lubricating oil and cooling systems of transmission gearing are to be in accordance with the requirements of 1.2.1.1 of this PART.

10.3.10.2 Lubricating oil is to be efficiently conveyed to all bearings, meshed gears and other portions requiring lubrication. The arrangement of oil pockets of sliding bearings is to be such that the effect of combined dynamic force of bearings is taken into account.

10.3.10.3 The lubricating oil system of transmission gearing for diesel engines is to be independent.

10.3.10.4 The lubricating oil pump for the transmission gearing is to comply with the requirements in 4.6.1, Chapter 4 of this PART.

10.3.10.5 Thermometers and pressure gauges are to be provided in the pressure lubricating oil systems, and working oil pressure gauge is to be fitted in addition when hydraulic system is employed. An oil level indicator is to be provided for the oil sump of splash lubrication.

10.3.10.6 Where the lubricating oil for the transmission gearing is circulated under pressure, provision is to be made for efficient filtration of the oil. The filters are to comply with the relevant provisions of 4.6.2.2 of this PART.

10.3.10.7 The lubricating oil temperature in the transmission gearing is not to exceed 70℃, and not to exceed 80℃ if roller bearing is fitted.

10.3.10.8 Cooling pipes passing through gear casings are not to have any detachable joint.

10.3.11 *Alarm*

10.3.11.1 Transmission gearing is to be fitted with alarm devices for low pressure of lubricating oil and in addition, an alarm device for high temperature of lubricating oil is to be fitted in case of transmission gearing whose input power is more than 1,470 kW.

10.3.12 *Emergency devices*

10.3.12.1 For hydraulically controlled transmission gearing in single screw ships, emergency mechanical means are to be provided to ensure that the ship can run at a reasonable speed in the event of failure of hydraulic control systems.

10.3.13 *Markings*

10.3.13.1 For reversible gearing, the directions of lever or handwheel for ahead and astern running are to

be marked at control station. As a common practice, to push the lever forward or to turn the handwheel clockwise is the way to move the ship ahead.

Section 4 TESTS

10.4.1 *Material tests*

10.4.1.1 Chemical composition and material test are to comply with the relevant requirements in ISC Rules for Materials and Welding.

10.4.2 *Balance tests*

10.4.2.1 All pinion and gear wheels are to be statically balanced. Where the linear velocity at the reference circle exceeds 25 m/s, dynamic balance test is to be made. Driven parts of the coupling are to be attached to the gear before balancing.

The residual dynamic unbalance is not to exceed:

$\frac{6.0m}{n}\times10^2$ N·mm, for transmission gearing of diesel engines;

$\frac{2.4m}{n}\times10^2$ N·mm, for transmission gearing of turbines.

where: m — mass of components, in kg;

n — maximum working speed of components, in r/min.

10.4.2.2 Balance test may, however, be omitted for diesel engine gearing, provided that the rotating components are of solid forged construction or have a solid forged centre with shrunk-on rim, and in both cases are machined to give a concentric and uniform cross-section.

10.4.3 *Gear mesh tests*

10.4.3.1 Gear mesh tests are to be carried out and gear contact spots are not to be less than the value in Table 10.4.3.1.

Contact spots *Table 10.4.3.1*

Contact spots	Grade of accuracy			
	6	7	8	9
Not less than (%) according to height	50	45	40	30
Not less than (%) according to length	70	60	50	40

10.4.4 Bench trials

10.4.4.1 The transmission gearing is to be tested according to the test programs approved by ISC during bench trials.

Appendix 1 APPRAISAL OF GEAR STRENGTH

1 *General*

1.1 **Application**

1.1.1 This Appendix is applicable to the enclosed gears intended for main propulsion and for essential auxiliary services of ships and mobile offshore units, which accumulate a large number of load cycles (several millions), whose gear set is intended to transmit a maximum continuous power equal to, or greater than 220 kW for gears intended for main propulsion and 110 kW for gears intended for essential auxiliary services. These requirements, however, may be applied to the enclosed gears, whose gear set is intended to transmit a maximum continuous power less than those specified above.

1.1.2 This Appendix is applicable to strength appraisal of involute spur and helical gears having parallel axis, and of bevel gears having transverse contact ratio $\varepsilon_{va} < 2$ for equivalent cylindrical gear.

1.1.3 This Appendix includes general, tooth surface contact stress, tooth root bending stress and alignment of gearbox shafting. All influence factors are defined regarding their physical interpretation. Some of the influence factors are determined by the gear geometry or have been established by conventions. These factors are to be calculated in accordance with the equations provided. Other factors, which are approximations, can be calculated according to methods acceptable to ISC.

1.2 Symbol, name and unit

1.2.1 The main symbols used in this Appendix are listed below. Other symbols introduced in connection with the definition of influence factors are described in the appropriate sections.

a — centre distance, in mm;
b — common face width, in mm;
$b_{1,2}$ — face width of pinion, wheel, in mm;
b_e — effective face width, in mm;
$d_{1,2}$ — reference diameter of pinion, wheel, in mm;
$d_{a1,2}$ — tip diameter of pinion, wheel, in mm;
$d_{b1,2}$ — base diameter of pinion, wheel, in mm;
$d_{f1,2}$ — root diameter of pinion, wheel, in mm;
$d_{w1,2}$ — working pitch diameter of pinion, wheel, in mm;
$d_{e1,2}$ — out pitch diameter of pinion, wheel, in mm;
F_t — nominal tangential load, in N;
$h_{1,2}$ — tooth depth, in mm;
$h_{a1,2}$ — addendum, in mm;
$h_{f1,2}$ — dedendum, in mm;
h_{ao} — addendum of cutter, in mm;
$h_{F1,2}$ — bending moment arm for load acting at the outer point of single tooth pair contact for pinion, wheel, in mm;
HV — Vickers hardness;
HRC — Rockwell hardness;
HB — Brinell hardness;
m_n — normal module, in mm;
$n_{1,2}$ — rotational speed of pinion, wheel, in r/min;
N_L — number of load cycles;
P — maximum continuous power or nominal power transmitted by the gear set (determined according to purpose), in kW;
P_{ro} — protuberance of tool, in mm;
P_{bt} — plane base terminal, in mm;
q_s — base circle parameter;
R_a — arithmetic mean of roughness, in μm;
R_z — mean peak-to-valley roughness, in μm;
S_{Fn} — tooth root chord in the critical section, in mm;
$T_{1,2}$ — torque in way of pinion, wheel, in N·m;
u — gear ratio;
V — linear velocity at pitch diameter, in m/s;
x — addendum modification coefficient of pinion, wheel;
$x_{hm1,2}$ — profile shift coefficient (midface);

$x_{sm1,2}$ — tooth thickness modification coefficient (midface);
$z_{1,2}$ — number of teeth;
$z_{n1,2}$ — virtual number of teeth;
$\alpha_{Fen1,2}$ — normal pressure angle relevant to direction of application of load at the outer point of single pair tooth contact of pinion, wheel, in °;
α_{pro} — cutter boss angle, in °;
α_n — normal pressure angle at reference cylinder, in °;
α_t — transverse pressure angle at reference cylinder, in °;
β — helix angle at reference cylinder, in °;
β_b — helix angle at base cylinder, in °;
ε_a — transverse contact ratio;
ε_β — overlap ratio;
ε_γ — total contact ratio;
$\rho_{ao1,2}$ — tip radius of tool of pinion, wheel, in mm;
$\rho_{F1,2}$ — root fillet radius at the 30° tangent point, in mm;
R_m — tensile strength, in N/mm²;
R_{eH} — yield point, in N/mm²;
$\delta_{1,2}$ — reference cone angle of pinion, wheel, in °;
$\delta_{a1,2}$ — tip angle of pinion, wheel, in °;
Σ — shaft angle, in °;
β_m — mean spiral angle, in °;
S — cone distance, in mm;
S_m — middle cone distance, in mm;
S_e — outer cone distance, in mm.

In calculation, pinion and wheel are indicated respectively by subscript 1 and subscript 2.

1.3 Definitions①

1.3.1 For the purpose of this Appendix:

(1) For internal gears, z_2, a, d_{a2}, d_2, d_{b2}, d_{w2} are negative.

(2) The pinion is defined as the gear with the less teeth, therefore:

$$|u| = \frac{|z_2|}{z_1} \geq 1$$

where: for external gears, u is positive; for internal gears, u is negative.

(3) In the equation of surface durability, b is the common face width on the pitch diameter.

(4) In the equation of tooth root bending stress, b_1 and b_2 are the face widths at the respective tooth roots. In any case, b_1 and b_2 are not to be taken as greater than b by more than one module m_n on either side.

(5) The common face width b may be used also in the equation of teeth root bending stress if significant crowning or end relief has been adopted.

(6) Geometry equations concerned are as follows:

$$\tan\alpha_t = \tan\alpha_n / \cos\beta$$

$$\tan\beta_b = \tan\beta\cos\alpha_t$$

$$d_{1,2} = z_{1,2}m_n / \cos\beta$$

$$d_{b1,2} = d_{1,2}\cos\alpha_t$$

$$d_{W1} = \frac{2a}{u+1}$$

$$d_{W2} = \frac{2au}{u+1}$$

$$a = 0.5(d_{w1} + d_{w2})$$

$$z_{n1,2} = z_{1,2} / (\cos^2\beta_b \cdot \cos\beta)$$

$$m_t = m_n / \cos\beta$$

$$inv\alpha = \tan\alpha - \pi\alpha / 180\,, \quad \alpha(°)$$

---

① The following definitions are mainly based on the ISO 6336 standard for the calculation of load capacity of spur and helical gears.

$$inv\alpha_{tw}=inv\alpha_t+2\tan\alpha_n(x_1+x_2)/(z_1+z_2) \quad \text{or} \quad \cos\alpha_{tw}=\frac{m_t(z_1+z_2)}{2a}\cos\alpha_t$$

$$a_{tw}=\arccos\left(\frac{d_{b1}+d_{b2}}{2a}\right), \quad \alpha_{tw}(^\circ)$$

$$x_{hm1}+x_{hm2}=\frac{(z_1+z_2)\cdot(inv\alpha_{tw}-inv\alpha_t)}{2\tan\alpha_n}$$

$$x_{hm1,2}=\frac{h_{ao}}{m_n}-\frac{d_{1,2}-d_{f1,2}}{2m_n}$$

$$\varepsilon_\alpha=\frac{0.5\sqrt{d_{a1}^2-d_{b1}^2}\pm0.5\sqrt{d_{a2}^2-d_{b2}^2}-a\sin a_{tw}}{\pi\cdot m_t\cdot\cos\alpha_t}$$

where the positive sign is used for external gears, the negative sign for internal gears.

$$\varepsilon_\beta=\frac{b\cdot\sin\beta}{\pi m_n}$$

where for double helix, b is to be taken as the width of one helix.

$$\varepsilon_r=\varepsilon_a+\varepsilon_\beta$$

$$v=\frac{\pi\cdot d_{1,2}n_{1,2}}{60\cdot10^3}$$

$$P_{bt}=\pi m_n\cos\alpha_t/\cos\beta$$

1.3.2 Equations for bevel gears

1.3.2.1 The calculation of bevel gear strength is technically based on the equivalent cylindrical gear at the bevel gear midsection. The calculation of geometric parameters of the equivalent cylindrical gear is shown in 1.3.2.3 of this Appendix.

1.3.2.2 Index *m* refers to the midsection of bevel gear; index *v* refers to the virtual (equivalent) cylindrical gear.

1.3.2.3 The geometric parameters of the equivalent cylindrical gear are to be calculated as follows:

(1) Number of teeth z_v:

$$z_{v1,2}=\frac{z_{1,2}}{\cos\delta_{1,2}}$$

For $\Sigma = 90°$:

$$z_{v1}=z_1\frac{\sqrt{u^2+1}}{u}$$

$$z_{v2}=z_2\sqrt{u^2+1}$$

(2) Gear ratio u_v:

$$u_v=u\frac{\cos\delta_1}{\cos\delta_2}=\frac{z_{v2}}{z_{v1}}$$

For $\Sigma = 90°$:

$$u_v=(\frac{z_2}{z_1})^2=u^2$$

(3) Reference diameter d_v:

$$d_{v1,2}=\frac{d_{m1,2}}{\cos\delta_{1,2}}=\frac{d_{e1,2}}{\cos\delta_{1,2}}\frac{S_m}{S_e}$$

For $\Sigma = 90°$:

$$d_{v1}=d_{m1}\frac{\sqrt{u^2+1}}{u}$$

$$d_{v2}=u^2d_{v1}$$

(4) Centre distance a_v:

$$a_v=\frac{d_{v1}+d_{v2}}{2}$$

(5) Tip diameter d_{va}:

$$d_{va1,2} = d_{v1,2} + 2h_{am1,2}$$

(6) Base diameter d_{vb}:

$$d_{vb1,2} = d_{v1,2} \times \cos\alpha_{vt}$$

$$\alpha_{vt} = \arctan(\frac{\tan\alpha_n}{\cos\beta_m})$$

(7) Helix angle at base cylinder β_{vb}:

$$\beta_{vb} = \arcsin(\sin\ \beta_m \cos a_n)$$

(8) Transverse contact ratio ε_{va}:

$$\varepsilon_{va} = \frac{g_{va}\cos\beta_m}{m_{mn}\pi\cos a_{vt}}$$

$$g_{va} = \frac{1}{2}\left[\sqrt{d_{va1}^2 - d_{vb1}^2} + \sqrt{d_{va2}^2 - d_{vb2}^2}\right] - a_v \sin a_{vt}$$

(9) Overlap ratio $\varepsilon_{v\beta}$:

$$\varepsilon_{v\beta} = \frac{b\sin\beta_m}{m_{mn}\pi}$$

(10) Modified contact ratio $\varepsilon_{v\gamma}$:

$$\varepsilon_{v\gamma} = \sqrt{\varepsilon_{v\alpha}^2 + \varepsilon_{v\beta}^2}$$

(11) Mean addendum h_{am}:

$$h_{am1,2} = m_{mn} \times (1 + x_{hm1,2})$$

1.3.2.4 The geometric parameters of the normal section of the equivalent cylindrical gear are to be calculated as follows:

(1) Number of teeth z_{vn}:

$$z_{vn1} = \frac{z_{v1}}{\cos^2\beta_{vb}\cos\beta_m}$$

$$z_{vn2} = u_v z_{vn1}$$

(2) Reference diameter d_{vn}:

$$d_{vn1} = \frac{d_{v1}}{\cos^2\beta_{vb}} = z_{vn1}m_{mn}$$

$$d_{vn2} = u_v d_{vn1} = z_{vn2}m_{mn}$$

(3) Centre distance a_{vn}:

$$a_{vn} = \frac{d_{vn1} + d_{vn2}}{2}$$

(4) Tip diameter d_{van}:

$$d_{van1,2} = d_{vn1,2} + d_{va1,2} - d_{v1,2} = d_{vn1,2} + 2h_{am1,2}$$

(5) Base diameter d_{vbn}:

$$d_{vbn1,2} = d_{vn1,2}\cos a_n = z_{vn1,2}m_{mn}\cos a_n$$

(6) Contact ratio ε_{van}:

$$\varepsilon_{van} = \frac{\varepsilon_{v\alpha}}{\cos^2\beta_{vb}}$$

1.4 Nominal tangential loads F_t, F_{mt}

1.4.1 The nominal tangential loads, F_t, F_{mt}, tangential to the reference cylinder and perpendicular to the relevant axial plane, are calculated directly from the maximum continuous power or nominal power transmitted by the gear set by means of the following equations:

$$T_{1,2} = \frac{30 \cdot 10^3 P}{\pi \cdot n_{1,2}}$$

Cylindrical gears:

$$F_t = \frac{2000 T_{1,2}}{d_{1,2}} = \frac{19.1 P \times 10^6}{n_{1,2} d_{1,2}}$$

Bevel gears:

$$F_{mt} = \frac{2000 T_{1,2}}{d_{m1,2}} = \frac{19.1 P \times 10^6}{n_{1,2} d_{m1,2}}$$

$$V_{mt} = \frac{d_{m1,2} n_{1,2}}{19098}$$

1.5 Relevant factors

1.5.1 Application factor K_A

1.5.1.1 The application factor K_A accounts for dynamic overloads from sources external to gearing. K_A, for gears designed for infinite life, is defined as the ratio between the maximum repetitive cyclic torque applied to the gear and the nominal rated torque. The nominal rated torque is defined by the rated power and speed and is the torque used in the rating calculations.

1.5.1.2 Factor K_A mainly depends on:

(1) characteristics of driving and driven machines;

(2) ratio of masses;

(3) type of couplings;

(4) operating conditions (overspeeds, changes in propeller load conditions, ...).

1.5.1.3 When operating near a critical speed of the drive system, a careful analysis of conditions must be made. The application factor K_A is to be determined by measurements or by system analysis. Where a value determined in such a way cannot be supplied, the following values in Table 1.5.1.3 may be considered.

Application factor K_A *Table 1.5.1.3*

Equipment type		K_A
Main propulsion diesel engines	With hydraulic coupling or equivalent parts	1.00
	With high elasticity coupling (general angle of torsion more than 6°)	1.30
	With elasticity coupling (general angle of torsion 2° to 6°)	1.40
	With other couplings	1.50
Main propulsion motors	Electric drive	1.00
Auxiliary gears	Electric motor and diesel engine, with hydraulic coupling or equivalent parts	1.00
	Diesel engine with high elasticity coupling (general angle of torsion more than 6°)	1.20
	Diesel engine with elasticity coupling (general angle of torsion 2° to 6°)	1.30
	Diesel engine, with other couplings	1.40

1.5.1.4 Where the ship using reduction gearing for main propulsion has an ice or PC N class notation, the nominal tangential force or the application factor is to be calculated according to the torque transmitted by reduction gearing in association with the ice or PC N class notation. See the relevant requirements in Chapter 14 of this PART or Chapter 13 of PART EIGHT of the Rules.

1.5.2 Load sharing factor K_γ

1.5.2.1 The load sharing factor K_γ accounts for the maldistribution of load in multiple path transmissions (dual tandem, epicyclic, double helix, etc.).

1.5.2.2 K_γ is defined as the ratio between the maximum load through an actual path and the evenly shared load. The factor mainly depends on accuracy and flexibility of the branches.

1.5.2.3 The load sharing factor K_γ is to be determined by measurements or by system analysis. Where a value determined in such a way cannot be supplied, the following values may be considered for epicyclic gears:

up to 3 planetary gears: K_γ =1.00;

4 planetary gears: K_γ =1.20;

5 planetary gears: K_γ =1.30;

6 planetary gears and over: K_γ =1.40;

other gear arrangements: K_γ = 1.00;

Bevels: K_γ = 1.00.

1.5.3 Internal dynamic factor K_V

1.5.3.1 The internal dynamic factor K_V accounts for internally generated dynamic loads due to vibrations of pinion and wheel against each other. K_V is defined as the ratio between the maximum load which dynamically acts on the tooth flanks and the maximum externally applied load ($F_t \cdot K_A \cdot K_\gamma$).

1.5.3.2 The factor K_V mainly depends on:

(1) transmission errors (depending on pitch and profile errors);

(2) masses of pinion and wheel;

(3) gear mesh stiffness variation as the gear teeth pass through the meshing cycle;

(4) transmitted load including application factor;

(5) pitch line velocity;

(6) dynamic unbalance of gears and shaft;
(7) shaft and bearing stiffness;
(8) damping characteristics of the gear system.

1.5.3.3 Where all the following conditions are satisfied, the internal dynamic factor K_V is to be calculated as follows:

(1) running velocity in the subcritical range, i.e.:

$$\frac{v \cdot z_1}{100}\sqrt{\frac{u^2}{1+u^2}} < 10 \quad \text{m/s}$$

(2) spur gears ($\beta = 0°$) and helical gears with $\beta \leq 30°$;
(3) pinion with relatively low number of teeth, $z_1 < 50$;
(4) solid disc wheels or heavy steel gear rim.

This method may be applied to all types of gears if $\frac{v \times z_1}{100}\sqrt{\frac{u^2}{1+u^2}} < 3$ m/s, as well as to helical gears where $\beta > 30°$.

For gears other than the above, reference is to be made to Method B outlined in the reference standard ISO 6336-1.

(1) For spur gears and for helical gears with overlap ratio $\varepsilon_\beta \geq 1$:

$$K_V = 1 + \left(\frac{K_1}{K_A \frac{F_t}{b}} + K_2 \right) \times \frac{V \times Z_1}{100} K_3 \sqrt{\frac{u^2}{1+u^2}}$$

If $K_A F_t/b$ is less than 100 N/mm, this value is assumed to be equal to 100 N/mm.
Numerical values for the factor K_1 are to be as specified in Table 1.5.3.3.

Values of K_1 *Table 1.5.3.3*

Accuracy grades①						
Gear type	3	4	5	6	7	8
spur gears	2.1	3.9	7.5	14.9	26.8	39.1
helical gears	1.9	3.5	6.7	13.3	23.9	34.8

① The accuracy grades are to be according to ISO 1328-1:2013. In case of mating gears with different accuracy grades, the grade corresponding to the lower accuracy is to be used.

For all accuracy grades, the factor K_2 is to be in accordance with the following: for
spur gears, K_2=0.0193;
for helical gears, K_2=0.0087.
Factor K is to be in accordance with the following:

If $\frac{v \times z_1}{100}\sqrt{\frac{u^2}{1+u^2}} \leqslant 0.2$, then $K_3 = 2.0$;

If $\frac{v \times z_1}{100}\sqrt{\frac{u^2}{1+u^2}} > 0.2$, then $K_3 = 2.071 - 0.357\frac{v \times z_1}{100}\sqrt{\frac{u^2}{1+u^2}}$

(2) For helical gears with overlap ratio $\varepsilon_\beta < 1$, the value K_V is determined by linear interpolation between values determined for spur gears ($K_{V\alpha}$) and helical gears ($K_{V\beta}$) in accordance with:

$$K_V = K_{V\alpha} - \varepsilon_\beta (K_{V\alpha} - K_{V\beta})$$

where: $K_{v\alpha}$ is the K_v value for spur gears, in accordance with 1.5.3.3(1);
$K_{v\beta}$ is the K_v value for helical gears, in accordance with 1.5.3.3(1).

1.5.3.4 K_V of bevel gears is to be calculated according to 1.5.3.3, with z_1, V, F_t therein being substituted by Z_{v1}, V_{mt}, F_{mt} respectively.

1.5.4 Face load distribution factors $K_{H\beta}$ and $K_{F\beta}$

1.5.4.1 The face load distribution factors, K_{Hh} for contact stress and K_{Fo} for tooth root bending stress, account for the effects of non-uniform distribution of load across the face width.

$K_{H\beta}$ is defined as follows:

$$K_{H\beta} = \frac{\text{maximum load per unit facewidth}}{\text{mean load per unit facewidth}}$$

$K_{F\beta}$ is defined as follows:

$$K_{F\beta} = \frac{\text{maximum bending stress at tooth root per unit facewidth}}{\text{mean bending stress at tooth root per unit facewidth}}$$

1.5.4.2 The factors $K_{H\beta}$ and $K_{F\beta}$ mainly depend on:

(1) gear tooth manufacturing accuracy;

(2) errors in mounting due to bore errors;

(3) bearing clearances;

(4) wheel and pinion shaft alignment errors;

(5) elastic deflection of gear elements, shafts, bearings, housing and foundations which support the gear elements;

(6) thermal expansion and distortion due to operating temperature;

(7) compensating design elements(tooth crowning, end relief, etc.).

1.5.4.3 The face load distribution factors K_{Hh} and K_{Fa} are to be determined according to the Method C outlined in the reference standard ISO 6336-1. Alternative methods acceptable to ISC may be applied.

In case the hardest contact is at the end of the face width, $K_{F\beta}$ is defined as follows:

$$K_{F\beta} = (K_{H\beta})^N$$

where: $N = \frac{(b/h)^2}{1+(b/h)+(b/h)^2}$, where (b/h) is the ratio of tooth width and tooth depth, to be taken as the minimum value of b_1/h_1 and b_2/h_2. Only one helical face width is to be taken for herringbone gear b. When $b/h < 3$ the value $b/h = 3$ is to be used.

In case of gears where the ends of the face width are lightly loaded or unloaded (end relief or crowning):

$K_{F\beta} = K_{H\beta}$.

1.5.4.4 Calculation of K_{Ha}, K_F for bevel gears

(1) $K_{H\beta}$ is to be calculated as follows:

For $b_e \geq 0.85b$:

$$K_{H\beta} = 1.5K_{H\beta\text{-}be}$$

For $b_e < 0.85b$:

$$K_{H\beta} = 1.5K_{H\beta\text{-}be}\ \frac{0.85b}{b_e}$$

where: $K_{H\beta\text{-}be}$ — assembling factor, see Table 1.5.4.4.

Assembling Factor $K_{H\beta\text{-}be}$ *Table 1.5.4.4*

Mounting conditions of pinion and wheel		
Both members straddle mounted	One member straddle mounted	Neither member straddle mounted
1.10	1.25	1.50

(2) $K_{F\beta}$ is to be calculated as follows:

$$K_{F\beta} = \frac{K_{H\beta}}{K_{F0}}$$

where: K_{F0} — curvature factor of tine length for bending strength, depending on helix angle and curvature in the direction of tine length, to be calculated as follows:

$$K_{F0} = 0.211\left(\frac{r_{c0}}{S_m}\right)^q + 0.789$$

$$q = \frac{0.279}{\lg(\sin\beta_m)}$$

where: r_{c0} — radius of tool, in mm;

S_m — middle cone distance, in mm;

β_m — helical angle at midpoint;

$K_{F0} = 1.15$, for $K_{F0} > 1.15$;

$K_{F0} = 1$, for $K_{F0} < 1$;

$K_{F0} = 1$, for straight or zero bevel gears.

1.5.5 Transverse load distribution factors $K_{H\alpha}$ and $K_{F\alpha}$

1.5.5.1 The transverse load distribution factors, $K_{H\alpha}$ for contact stress and $K_{F\alpha}$ for tooth root bending stress, account for the effects of pitch and profile errors on the transversal load distribution between two or more pairs of teeth in mesh.

1.5.5.2 The factors $K_{H\alpha}$ and $K_{F\alpha}$ mainly depend on:

(1) total mesh stiffness;

(2) total tangential load, i.e. equivalent tangential load, including load produced by K_A, K_V, $K_{H\beta}$;

(3) base pitch error;

(4) tip relief;
(5) running-in allowance.

1.5.5.3 The transverse load distribution factors $K_{H\alpha}$ and $K_{F\alpha}$ of cylindrical gears are to be determined according to Method B outlined in the reference standard ISO 6336-1.

1.5.5.4 K_{Ha} of bevel gears is to be determined as follows:

(1) Contact ratio $\varepsilon_{vr} \leq 2$ for equivalent cylindrical gear

$$K_{H\alpha} = \frac{\varepsilon_{vr}}{2}\left[0.9 + \frac{0.4c_r(f_{pt} - y_\alpha)}{F_{mtH}/b}\right]$$

$$F_{mtH} = F_{mt}K_AK_\gamma K_V K_{H\beta}$$

where: c_r — mesh stiffness, see 1.5.7 of this Appendix;

f_{pt} — pitch deviation of pinion or wheel, whichever is the greater;

y_a — running-in allowance, see 1.5.6 of this Appendix;

F_{mt} — nominal tangential load, see 1.4 of this Appendix;

For K_A, K_γ, K_V and $K_{H\beta}$, see 1.5 of this Appendix.

(2) Contact ratio $\varepsilon_{vr} > 2$ for equivalent cylindrical gear

$$K_{H\alpha} = 0.9 + \frac{0.4c_r(f_{pt} - y_\alpha)}{F_{mtH}/b}\sqrt{\frac{2(\varepsilon_{vr} - 1)}{\varepsilon_{vr}}}$$

(3) $K_{Ha} = 1$, for $K_{Ha} < 1$;

$K_{H\alpha} = \frac{\varepsilon_{vr}}{\varepsilon_{va}Z_{LS}^2}$, for $K_{H\alpha} > \frac{\varepsilon_{vr}}{\varepsilon_{va}Z_{LS}^2}$, where Z_{LS} is as given in 2.7 of this Appendix.

1.5.5.5 K_{Fa} of bevel gears is to be determined as follows:

$$K_{Fa} = K_{Ha}$$

$K_{Fa} = 1$, for $K_{Fa} < 1$;

$K_{F\alpha} = \frac{\varepsilon_{vr}}{\varepsilon_{va}Y_\varepsilon}$, for $K_{F\alpha} > \frac{\varepsilon_{vr}}{\varepsilon_{va}Y_\varepsilon}$ where Y_ε is as given in 3.6 of this Appendix.

1.5.6 Running-in allowance y_a

1.5.6.1 The running-in allowance y_a is the amount due to running-in by which the mesh alignment error is reduced from the start of the operation. In lack of direct experience, the value may be calculated according to Table 1.5.6.1.

Running-in Allowance *Table 1.5.6.1*

Gear material	Running-in allowance y_a	Limitation	
		Tangential speed at reference diameter (m/s)	Maximum running-in allowance (μm)
Quenched and tempered steels	$y_\alpha = \frac{160f_{pt}}{\sigma_{H\lim}}$	$v_{mt} \leq 5$	not limited
		$5 < v_{mt} \leq 10$	$y_a \leq 12800/\sigma_{H\lim}$
		$v_{mt} > 10$	$y_a \leq 6400/\sigma_{H\lim}$
Hardened steel and nitrided steels	$y_\alpha = 0.075f_{pt}$	Unlimited	$y_a \leq 3$
Two gears of different materials	$y_\alpha = \frac{y_{a1} + y_{a2}}{2}$	y_{a1} to be taken for pinion material; y_{a2} to be taken for wheel material	

1.5.7 Mesh stiffness c_γ

1.5.7.1 The mesh stiffness is the load to be applied on the line of contact to induce a deflection of 1 μm at 1 mm face width for one or more pairs of simultaneously meshed precision gears.

1.5.7.2 The mesh stiffness of bevel gears may be determined as follows:

$$c_\gamma = c_{\gamma 0}c_F c_b$$

where: $c_{\gamma 0}$ — mesh stiffness in the mean condition, taken as 20 N/mm·μm if no direct experience being available;

c_F and c_b — modification coefficients:

$c_F = 1$, for $F_{mt}K_A/b_e \geq 100$ N/mm;

$c_F = F_{mt}K_A/100b_e$, for $F_{mt}K_A/b_e < 100$ N/mm;

$c_b = 1$, for $b_e/b \geq 0.85$;

$c_b = b_e/0.85b$, for $b_e/b < 0.85$.

2 *Surface Durability*

2.1 Calculation requirements

2.1.1 The criterion for surface durability is based on the Hertz pressure on the operating pitch point or at the inner point of single pair contact. The surface contact stress σ_H must be equal to or less than the permissible contact stress σ_{HP}.

2.1.2 Surface contact stress and permissible contact stress of pinion and wheel are to be calculated respectively.

2.2 Surface contact stress σ_H

2.2.1 Surface contact stress σ_H is to be determined as follows:

$$\sigma_H = \sigma_{HO} \sqrt{K_A K_\gamma K_V K_{H\alpha} K_{H\beta}}$$

where: σ_{HO} = basic value of contact stress for pinion and wheel:

(1) Cylindrical gears:

for pinion:

$$\sigma_{HO} = Z_B Z_H Z_E Z_\varepsilon Z_\beta \sqrt{\frac{F_t}{d_1 b} \times \frac{u+1}{u}} \quad \text{N/mm}^2$$

for wheel:

$$\sigma_{HO} = Z_D Z_H Z_E Z_\varepsilon Z_\beta \sqrt{\frac{F_t}{d_1 b} \times \frac{u+1}{u}} \quad \text{N/mm}^2$$

(2) Bevel gears:

$$\sigma_{HO} = Z_{M\text{-}B} Z_H Z_E Z_{LS} Z_\beta Z_K \sqrt{\frac{F_{mt}}{d_{v1} l_{bm}} \times \frac{u_v+1}{u_v}} \quad \text{N/mm}^2$$

For the shaft angle $\Sigma = \delta_1 + \delta_2 = 90°$, the following applies:

$$\sigma_{HO} = Z_{M-B} Z_H Z_E Z_{LS} Z_\beta Z_K \sqrt{\frac{F_{mt}}{d_{m1} l_{bm}} \times \frac{\sqrt{u_v^2+1}}{u_v}} \quad \text{N/mm}^2$$

where: Z_B — single pair tooth contact factor for pinion , see 2.3 of this Appendix;
Z_D — single pair tooth contact factor for wheel, see 2.3 of this Appendix;
$Z_{M\text{-}B}$ — mid-zone factor, see 2.3 of this Appendix;
Z_H — zone factor, see 2.4 of this Appendix;
Z_E — elasticity factor, see 2.5 of this Appendix;
Z_ε — contact ratio factor, see 2.6 of this Appendix;
Z_{LS} — load sharing factor, see 2.7 of this Appendix;
Z_K — bevel gear factor (flank), see 2.8 of this Appendix;
Z_β — helix angle factor, see 2.9 of this Appendix;
l_{bm} — length of middle line of contact, see 3.7 of this Appendix;
for K_A, K_V, $K_{H\alpha}$ and $K_{H\beta}$, see 1.5 of this Appendix.

2.2.2 Permissible contact stress σ_{HP} is to be determined as follows:

$$\sigma_{HP} = (\sigma_{H\lim} / S_H) Z_N Z_L Z_V Z_R Z_W Z_X \quad \text{N/mm}^2$$

where: $\sigma_{H\lim}$ — endurance limit for contact stress, see 2.10 of this Appendix;
Z_N — life factor for contact stress, see 2.11 of this Appendix;
Z_L, Z_V, Z_R —lubrication factor, velocity factor and roughness factor respectively, see 2.12 of this Appendix;
Z_W — hardness ratio factor, see 2.13 of this Appendix;
Z_X — size factor for contact stress, see 2.14 of this Appendix;
S_H — safety factor for contact stress, see 2.15 of this Appendix.

2.3 Single pair tooth contact factors Z_B, Z_D and mid-zone factor $Z_{M\text{-}B}$

2.3.1 The single pair tooth contact factors, Z_B for pinion and Z_D for wheel, account for the influence of the tooth flank curvature on contact stresses at the inner point of single pair contact in relation to Z_H.

The mid-zone factor $Z_{M\text{-}B}$ is used to convert the contact stress at the pitch point to the contact stress at the midpoint M of loading, see Figure 2.3.1.

2.3.2 The single pair tooth contact factors, Z_B for pinion and Z_D for wheel, are to be determined as follows:

2.3.2.1 For spur gears, $\varepsilon_\beta = 0$

(1) $Z_B = M_1$ or 1, whichever is greater:

$$M_1 = \frac{\tan \alpha_{tw}}{\sqrt{\left[\sqrt{(\frac{d_{a1}}{d_{b1}})^2 - 1} - (\frac{2\pi}{z_1})\right]\left[\sqrt{(\frac{d_{a2}}{d_{b2}})^2 - 1} - (\varepsilon_\alpha - 1)(\frac{2\pi}{z_2})\right]}}$$

(2) $Z_D = M_2$ or 1, whichever is greater:

$$M_2 = \frac{\tan \alpha_{tw}}{\sqrt{\left[\sqrt{(\frac{d_{a2}}{d_{b2}})^2 - 1} - (\frac{2\pi}{z_2})\right]\left[\sqrt{(\frac{d_{a1}}{d_{b1}})^2 - 1} - (\varepsilon_\alpha - 1)(\frac{2\pi}{z_1})\right]}}$$

2.3.2.2 For helical gears,

(1) if $\varepsilon_\beta \geq 1$, $Z_B = Z_D = 1$;

(2) if $\varepsilon_\beta < 1$, to be calculated by interpolation:

$Z_B = M_1 - \varepsilon_\beta (M_1 - 1)$, and $Z_B \geq 1$;

$Z_D = M_2 - \varepsilon_\beta (M_2 - 1)$, and $Z_D \geq 1$.

2.3.2.3 For internal gears, $Z_D = 1$.

2.3.3 Mid-zone factor $Z_{M\text{-}B}$

The factor $Z_{M\text{-}B}$ may be calculated as follows:

$$Z_{M\text{-}B} = \frac{\tan \alpha_{vt}}{\sqrt{\left[\sqrt{(\frac{d_{va1}}{d_{vb1}})^2 - 1} - F_1 \frac{\pi}{z_{v1}}\right]\left[\sqrt{(\frac{d_{va2}}{d_{vb2}})^2 - 1} - F_2 \frac{\pi}{z_{v2}}\right]}}$$

where: F_1, F_2 — auxiliary factors, see Table 2.3.3.

Auxiliary Factors for Determination of Mid-Zone Factor *Table 2.3.3*

Overlap ratio of equivalent cylindrical gear	F_1	F_2
$\varepsilon_{v\beta} = 0$	2	$2(\varepsilon_{v\alpha} - 1)$
$0 < \varepsilon_{v\beta} \leq 1$	$2 + (\varepsilon_{v\alpha} - 2)\varepsilon_{v\beta}$	$2\varepsilon_{v\alpha} - 2 + (2 - \varepsilon_{v\alpha})\varepsilon_{v\beta}$
$\varepsilon_{v\beta} > 1$	$\varepsilon_{v\alpha}$	$\varepsilon_{v\alpha}$

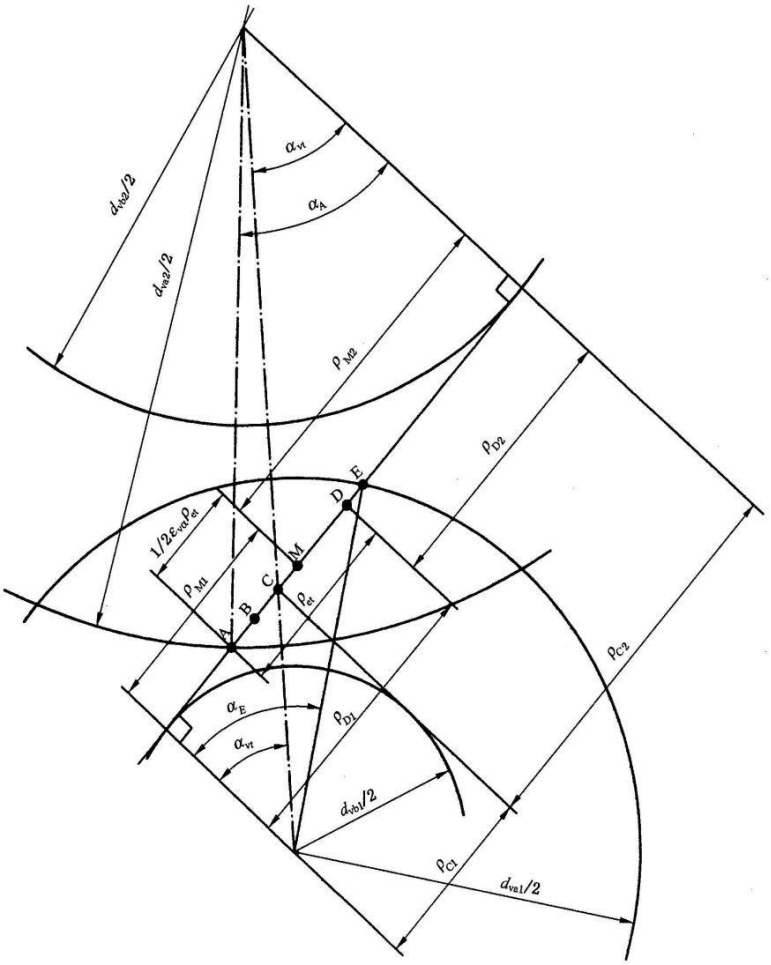

Figure 2.3.1 Radius of Curvature at Midpoint M and Single-Pair Mesh Point B of the Pinion, for Determination of Mid-Zone Factor

2.4 Zone factor Z_H

2.4.1 The zone factor, Z_H, accounts for the influence on the Hertzian pressure of tooth flank curvature at pitch point and transforms the tangential load at the reference cylinder to the normal load at the pitch cylinder.

2.4.2 The zone factor Z_H is to be calculated as follows:

(1) For cylindrical gears:

$$Z_H = \sqrt{\frac{2\cos\beta_b}{\cos^2\alpha_t \tan\alpha_{tw}}}$$

(2) For bevel gears:

$$Z_H = 2\sqrt{\frac{\cos\beta_{vb}}{\sin(2\alpha_{vt})}}$$

Some normal common pressure angles of bevel gears may be obtained from Figure 2.4.2.

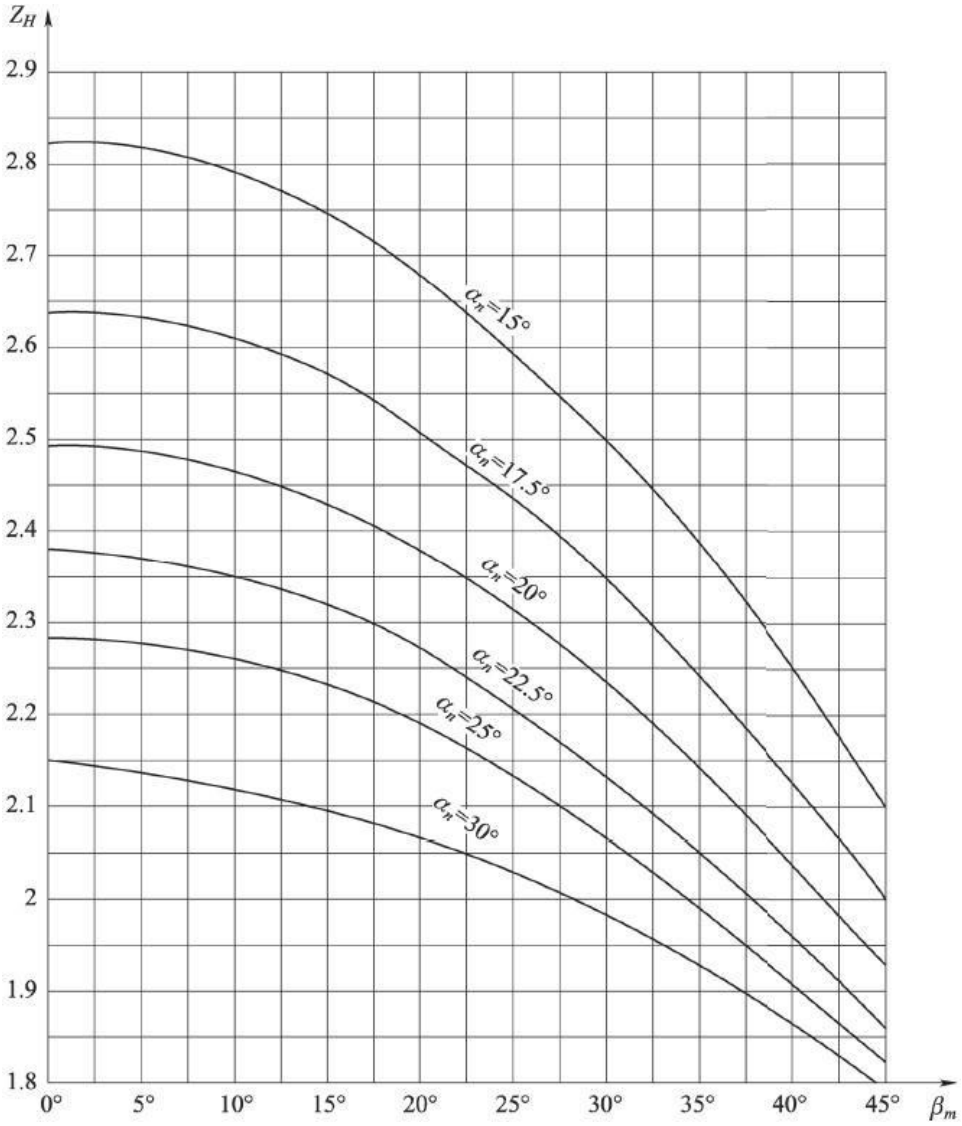

Figure 2.4.2 Zone Factor Z_H for X-Zero Bevel Gears

2.5 Elasticity factor Z_E

2.5.1 The elasticity factor, Z_E, accounts for the influence of the material properties E (modulus of elasticity) and v (Poisson's ratio) on the contact stress.

2.5.2 The factor Z_E is to be calculated as follows:

$$Z_E = \sqrt{\frac{1}{\pi\left(\frac{1-v_1^2}{E_1} + \frac{1-v_2^2}{E_2}\right)}}$$

For $E_1 = E_2 = E$ and $v_1 = v_2 = v$:

$$Z_E = \sqrt{\frac{E}{2\pi(1-v^2)}}$$

For $v = 0.3$ in respect to steel and hard aluminum alloys:

$$Z_E = \sqrt{0.175\,E}$$

Where the modulus of elasticity of the material of a pair is E_1 or E_2, the following applies:

$$E = \frac{2E_1E_2}{E_1 + E_2}$$

For steel gears (E = 206000 N/mm^2, v = 0.3):

$$Z_E = 189.8\ \sqrt{\text{N/mm}^2}$$

2.5.3 In other cases, reference is to be made to ISO 6336-2 standard.

2.6 Contact ratio factor Z_ε

2.6.1 The contact ratio factor, Z_ε, accounts for the influence of the transverse contact ratio and the overlap ratio on the specific surface load of gears.

2.6.2 The contact ratio factor Z_ε is to be calculated as follows:

Spur gears: $$Z_\varepsilon = \sqrt{\frac{4-\varepsilon_\alpha}{3}}$$

Helical gears: $$Z_\varepsilon = \sqrt{\frac{4-\varepsilon_\alpha}{3}(1-\varepsilon_\beta)+\frac{\varepsilon_\beta}{\varepsilon_\alpha}} \quad \text{for } \varepsilon_\beta < 1$$

$$Z_\varepsilon = \sqrt{\frac{1}{\varepsilon_\alpha}} \quad \text{for } \varepsilon_\beta \geq 1$$

2.7 Bevel gear load sharing factor Z_{LS}

2.7.1 The load sharing factor, Z_{LS}, accounts for the load sharing between two or more pairs of teeth in contact.

2.7.2 The load sharing factor, Z_{LS}, may be calculated as follows:

(1) $Z_{LS} = 1$ for $\varepsilon_{vr} \leq 2$ or $\varepsilon_{v\beta} < 1$.

(2) For $\varepsilon_{vr} > 2$ and $\varepsilon_{v\beta} > 1$, Z_{LS} is to be calculated as follows:

$$Z_{LS} = \left\{1+2\left[1-\left(\frac{2}{\varepsilon_{vr}}\right)^{1.5}\right]\sqrt{1-\frac{4}{\varepsilon_{vr}^2}}\right\}^{-0.5}$$

2.7.3 Where Z_{LS} obtained according to 2.7.2(2) is less than 0.837, Z_{LS} is to be taken as 0.837.

2.8 Bevel gear factor Z_K

2.8.1 The bevel gear factor Z_K is an empirical factor and accounts for the difference between bevel and cylindrical loading and adjusts the contact stresses so that the same permissible stresses may apply.

2.8.2 $Z_K = 0.8$ may be taken in lack of detailed data.

2.9 Helix angle factor Z_β

2.9.1 The helix angle factor, Z_β, accounts for the influence of helix angle on surface durability, allowing for such variables as the distribution of load along the lines of contact.

2.9.2 Z_β is to be calculated as follows:

(1) Cylindrical gears:

$$Z_\beta = \sqrt{\frac{1}{\cos\beta}}$$

(2) Bevel gears:

$$Z_\beta = \sqrt{\frac{1}{\cos\beta_m}}$$

2.10 Endurance limit for contact stress σ_{Hlim}

2.10.1 For a given material, σ_{Hlim} is the limit of repeated contact stress which can be permanently endured.

2.10.2 The value of σ_{Hlim} may be regarded as the level of contact stress which the material will endure without pitting for at least 5×10^7 load cycles. For this purpose, pitting is defined by:

(1) for not surface hardened gears: pitted area > 2% of total active flank area;

(2) for surface hardened gears: pitted area > 0.5% of total active flank area, or > 4% of one particular tooth flank area.

2.10.3 The σ_{Hlim} values are to correspond to a failure probability of 1% or less.

2.10.4 The endurance limit mainly depends on:

(1) material composition, cleanliness and defects;

(2) mechanical properties;

(3) residual stresses;

(4) heat treatment, depth of hardened zone, hardness gradient;

(5) material structure (forged, rolled bar, cast).

2.10.5 The endurance limit for contact stress σ_{Hlim} is to be determined, in general, making reference to values indicated in ISO 6336-5 standard, for material quality MQ.

2.11 Life factor Z_N

2.11.1 The life factor Z_N accounts for the higher permissible contact stress in case a limited life (number of cycles) is required.

2.11.2 The factor Z_N mainly depends on:

(1) material and heat treatment;
(2) number N_L of load cycles (service life);
(3) lubrication;
(4) failure criterion;
(5) required operational smoothness;
(6) pitch line velocity;
(7) cleanliness of material;
(8) plasticity and fracture toughness of material;
(9) residual stresses;
(10) influence factors (Z_R, Z_V, Z_L, Z_W, Z_X).

2.11.3 The life factor Z_N is to be determined according to Method B outlined in the reference standard ISO 6336-2.

2.12 Influence factors of lubrication film on contact stress, Z_L, Z_V and Z_R

2.12.1 The lubricant factor, Z_L, accounts for the influence of the type of lubricant and its viscosity. The velocity factor, Z_V, accounts for the influence of the pitch line velocity. The roughness factor, Z_R, accounts for the influence of the surface roughness on the surface endurance capacity. The factors may be determined for the softer material where gear pairs are of different hardness.

2.12.2 The factors mainly depend on:

(1) viscosity of lubricant in the contact zone;
(2) the sum of the instantaneous velocities of the tooth surfaces;
(3) load;
(4) relative radius of curvature at the pitch point;
(5) surface roughness of teeth flanks;
(6) hardness of pinion and gear.

2.12.3 The lubricant factor Z_L is to be calculated as follows:

$$Z_L = C_{ZL} + \frac{4(1.0 - C_{ZL})}{(1.2 + 134/\nu_{40})^2}$$

where: C_{ZL} — factor:

for 850 N/mm² ≤ σ_{Hlim} ≤ 1,200 N/mm²,

$$C_{ZL} = 0.83 + 0.08\frac{\sigma_{H_{lim}} - 850}{350}$$

if σ_{Hlim} < 850 N/mm², take C_{ZL} = 0.83;
if σ_{Hlim} >1,200 N/mm², take C_{ZL} = 0.91;

ν_{40} — nominal kinematic viscosity of the oil at 40℃.

2.12.4 The velocity factor Z_V is to be calculated as follows:

$$Z_V = C_{ZV} + \frac{2(1.0 - C_{ZV})}{\sqrt{0.8 + 32/V}}$$

where: C_{ZV} — factor:

for 850 N/mm² ≤ σ_{Hlim} ≤ 1200 N/mm²,

$$C_{ZV} = C_{ZL} + 0.02$$

if σ_{Hlim} <850 N/mm², take C_{ZV} = 0.85;
if σ_{Hlim} >1,200 N/mm², take C_{ZV} = 0.93.

2.12.5 The roughness factor Z_R is to be calculated as follows:

$$Z_R = \left(\frac{3}{R_{Z10}}\right)^{C_{ZR}}$$

where: R_{Z10} — relative mean roughness (curvature radius relative to pitch point ρ_{red} = 10 mm):

$$R_{Z10} = \frac{R_{Z1} + R_{Z2}}{2} \sqrt[3]{\frac{10}{\rho_{red}}}$$

R_{Z1} and R_{Z2} —mean peak-to-valley roughness determined respectively for the pinion and the wheel (refer to ISO 6336-2 standard);

ρ_{red} — relative radius of curvature, to be determined from the following equation:

(1) for cylindrical gears:

$$\rho_{red} = \frac{\rho_1 \rho_2}{\rho_1 + \rho_2}$$

(2) for bevel gears:

$$\rho_{red} = \frac{\rho_{v1} \rho_{v2}}{\rho_{v1} + \rho_{v2}}$$

where: $\rho_{1,2} = 0.5 \times d_{b1,2} \times \tan\alpha_{tw}$;

$\rho_{v1,2} = 0.5 \times d_{vb1,2} \times \tan\alpha_{tw}$.

If the roughness stated is an arithmetic mean roughness, i.e. R_a value (= *CLA* value) (= *AA* value) the following approximate relationship can be applied:

$$R_a = CLA = AA = R_z/6$$

C_{ZR} — factor:

for 850 N/mm² ≤ σ_{Hlim} ≤ 1,200 N/mm², C_{ZR} = 0.32 – 0.0002σ_{Hlim};

if σ_{Hlim} < 850 N/mm², take C_{ZR} =0.15;

if σ_{Hlim} > 1,200 N/mm², take C_{ZR} =0.08.

2.13 Hardness ratio factor Z_W

2.13.1 The hardness ratio factor, Z_W, accounts for the increase of surface durability of a soft steel gear meshing with a significantly harder gear (mean peak-to-valley roughness $R_Z \leq 6$ μm or rough arithmetic mean value $R_a \leq 1$ μm) with a smooth surface in the following cases.

If $HB < 130$, $Z_W = 1.2 \times (\frac{3}{R_{zH}})^{0.15}$;

If $130 \leq HB \leq 470$, $Z_W = (1.2 - \frac{HB - 130}{1700}) \times (\frac{3}{R_{zH}})^{0.15}$;

If $HB > 470$, $Z_W = (\frac{3}{R_{zH}})^{0.15}$.

(1) Surface-hardened pinion with through-hardened wheel

where: HB = Brinell hardness of the tooth flanks of the softer gear of the pair;

R_{zH} — equivalent roughness, μm

$$R_{zH} = \frac{R_{z1} \times (\frac{10}{\rho_{red}})^{0.33} \times (\frac{R_{z1}}{R_{z2}})^{0.66}}{(v \times v_{40}/1500)^{0.33}}$$

ρ_{red}— relative radius of curvature.

(2) Through-hardened pinion and wheel

When the pinion is substantially harder than the wheel, the work hardening effect increases the load capacity of the wheel flanks. Z_W applies to the wheel only, not to the pinion.

If $HB_1/HB_2 < 1.2$, $Z_W = 1$

If $1.2 \leq HB_1/HB_2 \leq 1.7$, $Z_W = 1 + \left(0.00898 \frac{HB_1}{HB_2} - 0.00829\right) \times (u - 1)$

If $HB_1/HB_2 > 1.7$, $Z_W = 1 + 0.00698 \cdot (u - 1)$

If gear ratio $u > 20$ then the value $u = 20$ is to be used.

In any case, if calculated $Z_W < 1$ then the value $Z_W = 1.0$ is to be used.

2.14 Size factor of contact stress, Z_X

2.14.1 The size factor, Z_X, accounts for the influence of tooth dimensions on permissible contact stress and reflects the non-uniformity of material properties.

2.14.2 The factor mainly depends on:

(1) material and heat treatment;

(2) tooth and gear dimensions;
(3) ratio of case depth to tooth size;
(4) ratio of case depth to equivalent radius of curvature.

2.14.3 For through-hardened gears and for surface-hardened gears with adequate case depth relative to tooth size and radius of relative curvature, Z_x =1. When the case depth is relatively shallow, then a smaller value of Z_X is to be chosen.

2.15 Safety factor for contact stress, S_H

2.15.1 The safety factor for contact stress, S_H, can be assumed by taking into account the type of application. The safety factor for contact stress S_H is to satisfy the following guidance values:

Main propulsion gears: $1.20 \le S_H \le 1.40$;

Auxiliary gears: $1.15 \le S_H \le 1.20$.

For gearing of duplicated independent propulsion or auxiliary machinery, a reduced value can be assumed.

3 *Tooth Root Bending Strength*

3.1 Calculation requirements

3.1.1 The criterion for tooth root bending strength is the permissible limit of local tensile strength in the root fillet. The root stress σ_F is to be equal to or less than the permissible root stress σ_{FP}.

3.1.2 The root stress σ_F and the permissible root stress σ_{FP} are to be calculated separately for the pinion and the wheel.

3.1.3 The following formulae and definitions apply to gears having rim thickness greater than 3.5 m_n.

3.1.4 The result of rating calculations made by following this method are acceptable for normal pressure angles up to 25° and reference helix angles up to 30°. For larger pressure angles and large helix angles, the calculated results are to be confirmed by experience as by ISO 6336-3 Method A and the relevant standard.

3.2 Tooth root bending stress for pinion and wheel σ_F

3.2.1 Tooth root bending stress for pinion and wheel σ_F is to be calculated as follows:

(1) For cylindrical gears:

$$\sigma_F = \frac{F_t}{bm_n} Y_F Y_S Y_\beta Y_B Y_{DT} K_A K_\gamma K_v K_{F\alpha} K_{F\beta} \le \sigma_{FP}$$

(2) For bevel gears:

$$\sigma_F = \frac{F_{mt}}{bm_{mn}} Y_{Fa} Y_{Sa} Y_\varepsilon Y_K Y_{LS} K_A K_\gamma K_v K_{F\beta} K_{F\alpha} \le \sigma_{FP}$$

where: Y_F, Y_{Fa} — tooth form factor, see 3.3 of this Appendix;

Y_S, Y_{Sa} — stress correction factor, see 3.4 of this Appendix;

Y_β — helix angle factor, see 3.5 of this Appendix;

$Y\varepsilon$ — contact ratio factor, see 3.6 of this Appendix;

Y_K — bevel gear factor, see 3.7 of this Appendix;

Y_{LS} — load sharing factor, see 3.8 of this Appendix;

Y_B — rim thickness factor, see 3.15 of this Appendix;

Y_{DT} — deep tooth factor, see 3.16 of this Appendix;

for F_t, K_A, K_γ, K_V, K_{Fa} and $K_{F\beta}$, see 1.4 and 1.5 of this Appendix;

for b and m_n, see 1.2 of this Appendix.

3.2.2 Permissible tooth root bending stress for pinion and wheel, σ_{FP}, is to be calculated as follows:

$$\sigma_{FP} = \frac{\sigma_{FE} \times Y_N \times Y_d}{S_F} Y_{\delta relT} \times Y_{RrelT} \times Y_X \quad \text{N/mm}^2$$

where: σ_{FE} — bending endurance limit, see 3.9 of this Appendix;

Y_d — design factor, see 3.10 of this Appendix;

Y_N — life factor, see 3.11 of this Appendix;

$Y_{\delta relT}$ — relative notch sensitivity factor, see 3.12 of this Appendix;

Y_{RrelT} — relative surface factor, see 3.13 of this Appendix;

Y_X — size factor of bending stress, see 3.14 of this Appendix;

S_F — safety factor for tooth root bending stress, see 3.17 of this Appendix.

3.3 Tooth form factors Y_F, Y_{Fa}

3.3.1 The tooth form factors, Y_F and Y_{Fa}, represent the influence on nominal bending stress of the tooth form with load applied at the outer point of single pair tooth contact.

3.3.2 Y_F and Y_{Fa} are to be determined separately for the pinion and the wheel. In the case of helical gears, the form factors for gearing are to be determined in the normal section, i.e. for the virtual spur gear with virtual number of teeth z_n.

3.3.3 Tooth form factor of cylindrical gears, Y_F

For the pinion and the wheel, the tooth form factor is to be calculated as follows:

$$Y_F = \frac{6\frac{h_F}{m_n}\cos\alpha_{Fen}}{(\frac{S_{Fn}}{m_n})^2\cos\alpha_n}$$

where: h_F — bending moment arm for tooth root bending stress for application of load at the outer point of single tooth pair contact, in mm;

S_{Fn} — tooth root normal chord in the critical section, in mm;

α_{Fen} — pressure angle at the outer point of single tooth pair contact in the normal section, in °.

h_F, α_{Fen} and S_{Fn} are shown in Figure 3.3.3.

For the calculation of h_F, α_{Fen} and S_{Fn}, the procedure outlined in the reference standard ISO 6336-3 (Method B) is to be used.

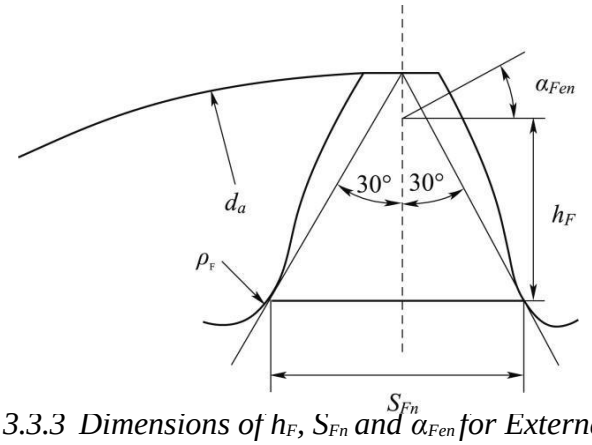

Figure 3.3.3 Dimensions of h_F, S_{Fn} and α_{Fen} for External Gear

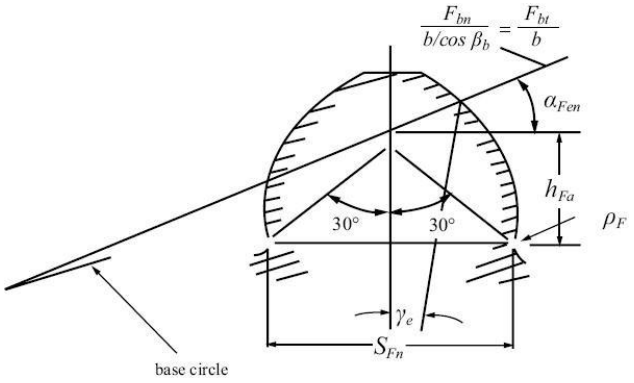
3.3.4 Tooth form factor for bevel gears, Y_{Fa}



3.3.4.1 The tooth form factor Y_{Fa} represents the influence on nominal bending stress of the tooth form with load applied at the tooth tip. In calculation by this method, the section at 30° tangent point of the tooth root transition curve beyond the normal tooth profile of the equivalent cylindrical gear is the critical section.

3.3.4.2 The tooth form factor is to be determined separately for the pinion and the wheel. Depending on different manufacturing methods, specific equations are respectively given in 3.3.4.4 and 3.3.4.5, with relevant parameters being defined in Figure 3.3.4.

3.3.4.3 The tooth form factor of generated gears is also to comply with the following:

(1) the contact point of the 30° tangent lies on the fillet curve generated by cutter tip radius;

(2) the cutter must have a tip fillet radius ($\rho_{a0} \neq 0$).

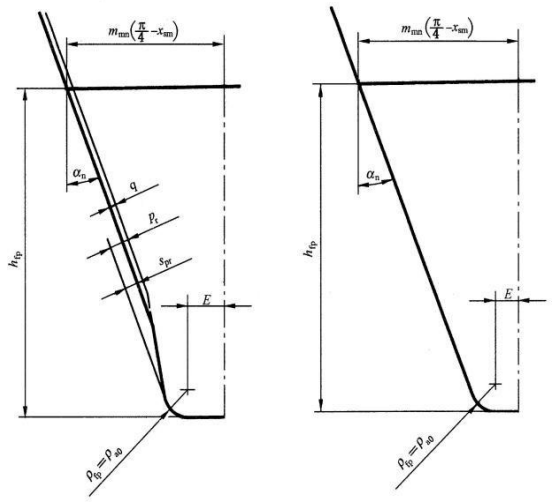


Figure 3.3.4 Factors Influencing Tooth Form of Bevel Gears

3.3.4.4 The tooth form factor of generated gears may be calculated as follows:
(1) Tooth form factor Y_{Fa}:

$$Y_{Fa}=\frac{6(\frac{h_{Fa}}{m_{mn}})\cos\alpha_{Fan}}{(\frac{S_{Fn}}{m_{mn}})^2\cos\alpha_n}$$

(2) For calculation of tooth root chord S_{Fn} in the critical section and bending moment arm h_{Fa}, the auxiliary values E, G, H and θ are first to be determined:

$$E=(\frac{\pi}{4}-x_{sm})m_{mn}-h_{ao}\tan\alpha_n-\frac{\rho_{ao}(1-\sin\alpha_n)-s_{pr}}{\cos\alpha_n}$$

$$G=\frac{\rho_{ao}}{m_{mn}}-\frac{h_{ao}}{m_{mn}}+x_{hm}$$

$$H=\frac{2}{z_{vn}}(\frac{\pi}{2}-\frac{E}{m_{mn}})-\frac{\pi}{3}$$

$$\theta=\frac{2G}{z_{vn}}\tan\theta-H$$

It is recommended to take the initial value $\theta=\pi/6$ to obtain θ by iterative method.

(3) Tooth root chord S_{Fn} in the critical section:

$$\frac{S_{Fn}}{m_{mn}}=Z_{vn}\sin(\frac{\pi}{3}-\theta)+\sqrt{3}(\frac{G}{\cos\theta}-\frac{\rho_{ao}}{m_{mn}})$$

(4) Tooth root fillet radius ρ_F in the critical section:

$$\frac{\rho_F}{m_{mn}}=\frac{\rho_{ao}}{m_{mn}}+\frac{2G^2}{\cos\theta(z_{vn}\cos^2\theta-2G)}$$

(5) Bending moment arm h_{Fa}:

$$\alpha_{an}=\arccos(d_{vbn}/d_{van})$$

$$\gamma_a=\frac{1}{z_{vn}}[\frac{\pi}{2}+2(x_{hm}\tan\alpha_n+x_{sm})]+inv\alpha_n-inv\alpha_{an}$$

$$\alpha_{Fan}=\alpha_{an}-\gamma_a$$

$$\frac{h_{Fa}}{m_{mn}}=\frac{1}{2}\left[(\cos\gamma_a-\sin\gamma_a\tan\alpha_{Fan})\frac{d_{van}}{m_{mn}}-z_{vn}\cos(\frac{\pi}{3}-\theta)-\frac{G}{\cos\theta}+\frac{\rho_{ao}}{m_{mn}}\right]$$

For gears having a basic rack profile of $\alpha_n=20°$, $h_{a0}/m_{mn}=1.25$, $\rho_{a0}/m_{mn}=0$ and $x_{sm}=0$, the tooth form factor may be obtained from Figure 3.3.4.4.

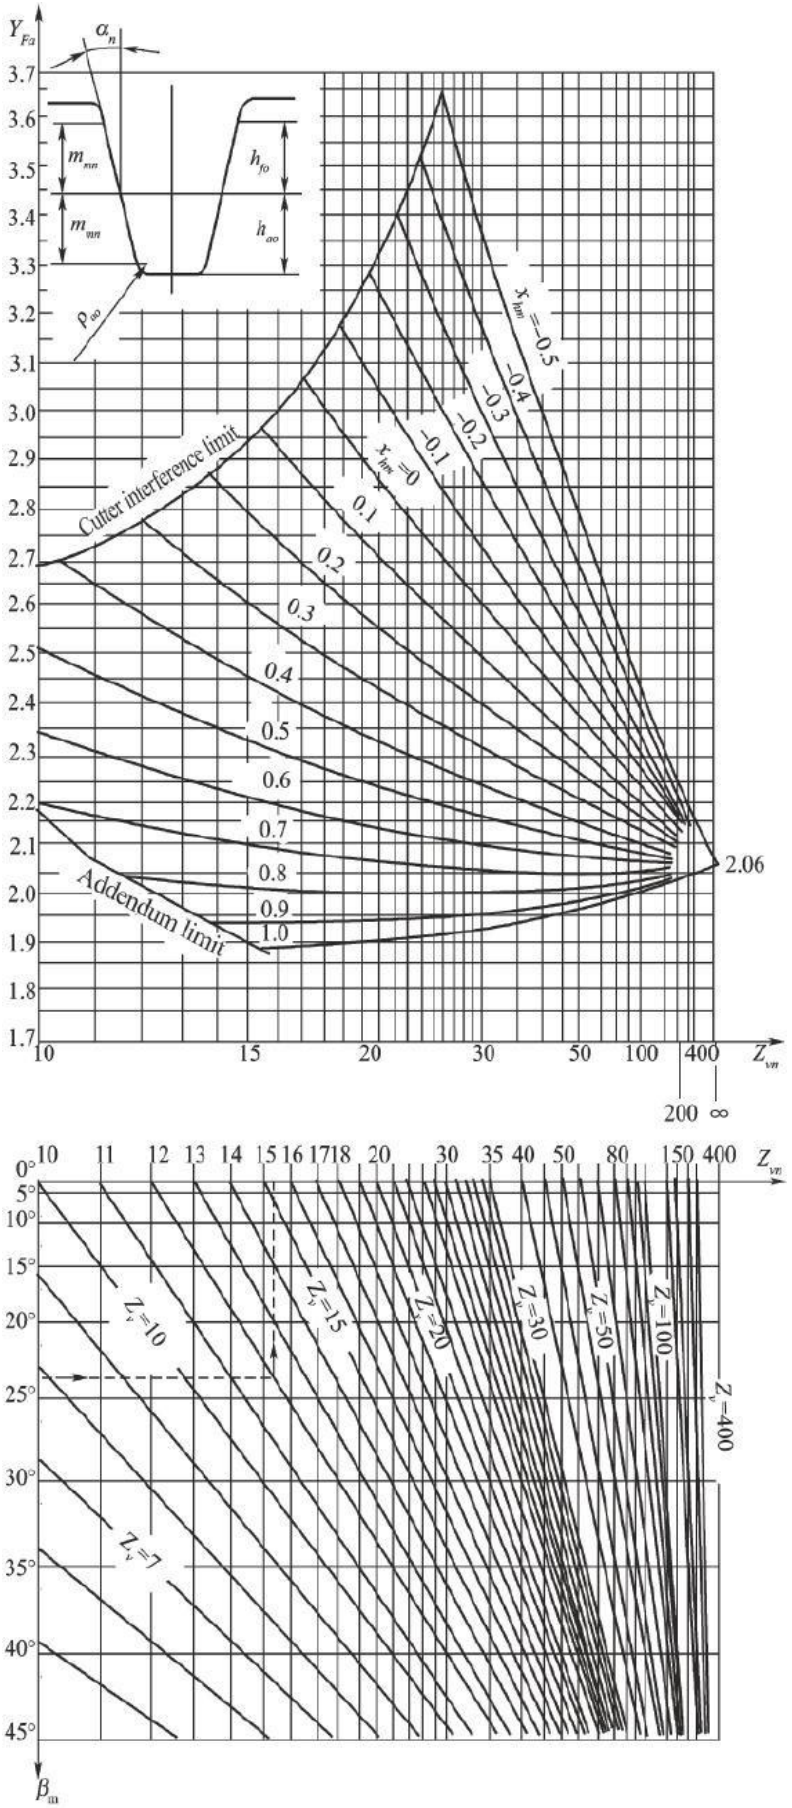

Figure 3.3.4.4 Tooth Form Factor of Generated Gears

3.3.4.5 Tooth form factor Y_{Fa} of form cutting

The tooth form factor of form cutting may be calculated as follows:

(1) Tooth root chord in the critical section

$$s_{Fn2} = \pi m_{mn} - 2E - 2\rho_{a02}\cos 30^{o}$$

where: E is to be calculated according to 3.3.4.4(2).

(2) Fillet radius at contact point of 30° tangent

$$\rho_{F2} = \rho_{a02}$$

(3) Bending moment arm

$$h_{Fa2} = h_{a02} - \frac{\rho_{a02}}{2} + m_{mn} - (\frac{\pi}{4} + x_{sx2} - \tan a_n) m_{mn} \tan a_n$$

(4) The tooth form factor is to be calculated as follows:

$$Y_{Fa} = \frac{6\frac{h_{Fa2}}{m_{mn}}}{(\frac{S_{Fn2}}{m_{mn}})^2}$$

3.4 Stress correction factors Y_S, Y_{Sa}

3.4.1 The stress correction factors are used to convert the nominal bending stress to the local tooth root stress, taking into account the effects of stress concentration at the tooth root transition curve and stresses other than bending stresses on the root stress.

3.4.2 The factors apply to the load application at the outer point of single tooth pair contact and are to be determined separately for the pinion and for the wheel.

3.4.3 Y_S value is to be determined with the following equation (having range of validity: $1 \le q_s < 8$):

(1) Stress correction factor Y_S of cylindrical gears:

$$Y_S = (1.2 + 0.13L) q_s^{(\frac{1}{1.21+2.3/L})}$$

(2) Stress correction factor Y_{Sa} of bevel gears:

$$Y_{Sa} = (1.2 + 0.13L_a) q_s^{(\frac{1}{1.21+2.3/L_a})}$$

where : q_s — notch parameter, $q_s = \frac{S_{Fn}}{2\rho_F}$

$$L = \frac{S_{Fn}}{h_F}$$

$$L_a = \frac{S_{Fn}}{h_{Fa}}$$

ρ_F = root fillet radius in the critical section, mm. For the calculation of ρ_F the procedure outlined in the reference standard ISO 6336-3 is to be used.

For bevel gears having the basic rack profile of the tooth with $\alpha_n = 20^{o}, h_{a0}/m_{mn} = 1.25, \rho_{a0}/m_{mn} = 0$ and x_{sm}= 0, the stress correction factors may be obtained from Figure 3.4.3.

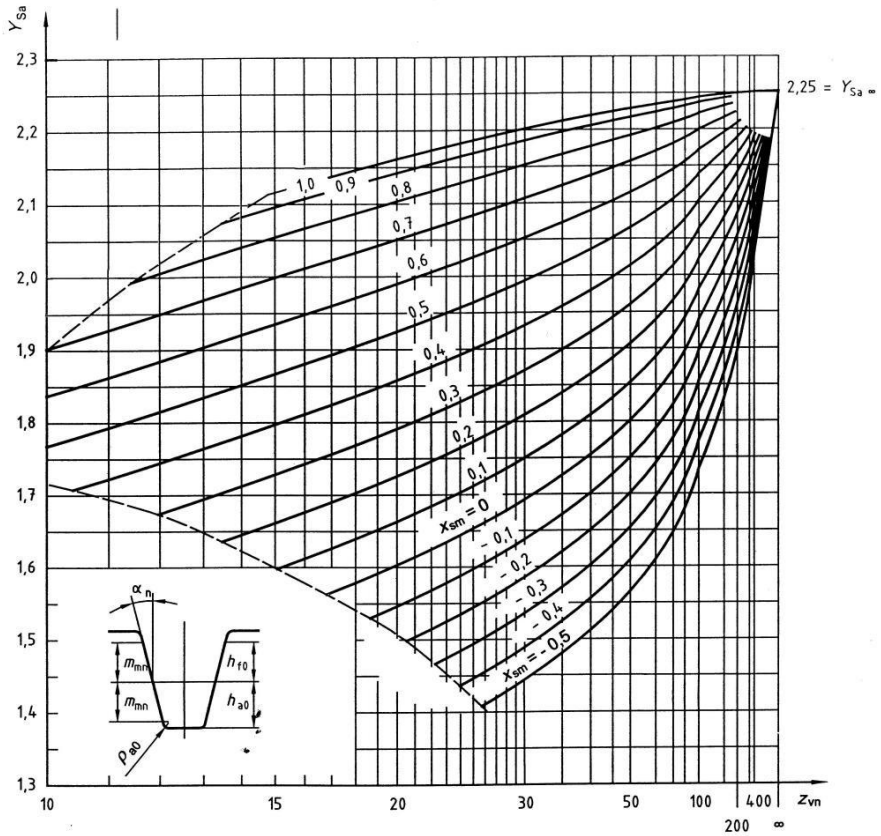

Figure 3.4.3 Stress Correction Factors for Tooth Form Factor of Generated Gear with Load Applied at Tooth Tip

3.5 Helix angle factor Y_β

3.5.1 The helix angle factor, Y_β, covers the effects of an oblique line of contact caused by the helix angle of cylindrical gears on the root stress.

3.5.2 The helix angle factor, Y_β is to be calculated as follows:

$$Y_\beta = 1 - \varepsilon_\beta \frac{\beta}{120}$$

where: β — reference helix angle in degrees, 30° is substituted for β > 30°;
ε_β — overlap ratio, the value 1.0 is substituted for ε_β when ε_β > 1.0.

3.6 Contact ratio factor Y_ε

3.6.1 The contact ratio factor Y_ε covers the effects of an oblique line of contact caused by the helix angle of bevel gears on the root stress.

3.6.2 The contact ratio factor Y_ε may be calculated as follows:

(1) For $\varepsilon_{v\beta} = 0$:

$$Y_\varepsilon = 0.25 + \frac{0.75}{\varepsilon_{va}}$$

(2) For $0 < \varepsilon_{v\beta} \leq 1$:

$$Y_\varepsilon = 0.25 + \frac{0.75}{\varepsilon_{va}} - \varepsilon_{v\beta}\left(\frac{0.75}{\varepsilon_{va}} - 0.375\right)$$

For $\varepsilon_{v\beta} > 1$:

$$Y_\varepsilon = 0.625$$

3.6.3 Where Y_ε calculated according to 3.6.2 is less than 0.625, Y_ε is to be taken as 0.625.

3.7 Bevel gear factor Y_K

3.7.1 The bevel gear factor Y_K accounts for the differences between bevel and cylindrical gears in respect to root stress.

3.7.2 The bevel gear factor Y_K may be calculated as follows:

$$Y_K = (\frac{1}{2} + \frac{l'_{bm}}{2b})^2 \frac{b}{l'_{bm}}$$

$$l'_{bm} = l_{bm} \cos \beta_{vb}$$

where: l'_{bm} — projected length of the middle line of contact;

l_{bm} — length of the middle line of contact:

For $\varepsilon_{v\beta} < 1$: $l_{bm} = \frac{b\varepsilon_{va}}{\cos \beta_{vb}} \frac{\sqrt{\varepsilon_{vr}^2 - [(2 - \varepsilon_{va})(1 - \varepsilon_{v\beta})]^2}}{\varepsilon_{vr}^2}$;

For $\varepsilon_{v\beta} \geq 1$: $l_{bm} = \frac{b\varepsilon_{va}}{\cos \beta_{vb} \varepsilon_{vr}}$.

3.8 Load sharing factor Y_{LS}

3.8.1 The load sharing factor, Y_{LS}, accounts for the distribution of load between two or more pairs of teeth.

3.8.2 The factor Y_{LS} may be calculated as follows:

$$Y_{LS} = Z_{LS}^2$$

where: Z_{LS} — load sharing factor, see 2.7 of this Appendix.

3.8.3 Where Z_{LS} calculated according to 3.8.2 is less than 0.7, Z_{LS} is to be taken as 0.7.

3.9 Bending endurance limit σ_{FE}

3.9.1 For a given material, bending endurance limit σ_{FE} is the local tooth root stress which can be permanently endured. According to the reference standard the number of 3×10^6 cycles is regarded as the beginning of the endurance limit. The σ_{FE} values are to correspond to a failure probability 1% or less.

σ_{FE} is defined as the unidirectional pulsating stress with a minimum stress of zero (disregarding residual stresses due to heat treatment). Other conditions such as alternating stress or prestressing etc., are covered by the design factor Y_d.

3.9.2 The endurance limit σ_{FE} mainly depends on:

(1) material composition, cleanliness and defects;

(2) mechanical properties;

(3) residual stresses;

(4) heat treatment, depth of hardened zone, hardness gradient;

(5) material structure (forged, rolled bar, cast).

3.9.3 The bending endurance limit σ_{FE} is to be determined, in general, making reference to values indicated in ISO 6336-5 standard, for material quality MQ.

3.10 Design factor Y_d

3.10.1 The design factor, Y_d, takes into account the influence of load reversing and shrink fit prestressing on the tooth root strength, relative to the tooth root strength with unidirectional load as defined for σ_{FE}.

3.10.2 The design factor, Y_d, is to be determined as follows:

(1) for gears with unidirectional load: $Y_d = 1.0$;

(2) for gears with occasional part load in reversed direction, such as idler gear and planet wheel: $Y_d = 0.7$;

(3) for gears with performance in reversing: $Y_d = 0.9$;

(4) for gears shrinking on assembled gear rings: $Y_d = 0.8$.

3.11 Life factor Y_N

3.11.1 The life factor Y_N accounts for the higher tooth root bending stress permissible when a limited life (number of cycles) is required.

3.11.2 The factor Y_N mainly depends on:

(1) material and heat treatment;

(2) number of load cycles (service life);

(3) influence factors ($Y_{\delta relT}$, Y_{RrelT}, Y_X).

3.11.3 The life factor Y_N may also be determined according to Method B outlined in the reference standard ISO 6336-3.

3.12 Relative notch sensitivity factor $Y_{\delta relT}$

3.12.1 The relative notch sensitivity factor, $Y_{\delta relT}$, indicates the extent to which the theoretically concentrated stress lies above the fatigue endurance limit.

3.12.2 The factor $Y_{\delta relT}$ mainly depends on:

(1) material;

(2) relative stress gradient.

3.12.3 $Y_{\delta relT}$ is to be determined as follows:

$$Y_{\delta relT}=\frac{1+\sqrt{0.2\rho'(1+2q_s)}}{1+\sqrt{1.2\rho'}}$$

where: q_s = notch parameter, see 3.4 of this Appendix;

ρ' = slip-layer thickness, mm, from Table 3.12.3.

Value of Slip-layer Thickness ρ' *Table 3.12.3*

Material		ρ'(mm)
Case hardened steels, flame or induction hardened steels		0.0030
Through-hardened steels①, yield point R_e	500 N/mm^2	0.0281
	600 N/mm^2	0.0194
	800 N/mm^2	0.0064
	1000 N/mm^2	0.0014
Nitrided steels		0.1005

Note: ① The given values of ρ' can be interpolated for values of R_e not stated above.

3.13 Relative surface factor Y_{RrelT}

3.13.1 The relative surface factor, Y_{RrelT}, takes into account the dependence of the root strength on the surface condition in the tooth root fillet, mainly the dependence on the peak-to-valley surface roughness.

3.13.2 The relative surface factor, Y_{RrelT} is to be determined from Table 3.13.2. The method applied here is only valid when scratches or similar defects deeper than $2R_z$ are not present.

Relative surface factor Y_{RrelT} *Table 3.13.2*

Material and heat treatment	$R_Z < 1$	$1 \le R_Z \le 40$
case hardened steels, through-hardened steels ($R_m \ge 800$ N/mm^2)	1.120	$1.674 - 0.529\ (R_Z + 1)^{0.1}$
normalised steels ($R_m < 800$ N/mm^2)	1.070	$5.306 - 4.203\ (R_Z + 1)^{0.01}$
nitrided steels	1.025	$4.299 - 3.259\ (R_Z + 1)^{0.0058}$

Notes: ① R_z — mean peak-to-valley roughness of tooth root fillets, in μm.

② If the roughness stated is an arithmetic mean roughness, i.e. R_a value (= *CLA* value) (= *AA* value) the following approximate relationship can be applied: $R_a = CLA = AA = R_Z/6$.

3.14 Size factor of bending stress Y_X

3.14.1 The size factor of bending stress, Y_X, takes into account the decrease of the strength with increasing size.

3.14.2 The factor Y_X mainly depends on:

(1) material and heat treatment;

(2) tooth and gear dimensions;

(3) ratio of case depth to tooth size.

3.14.3 The size factor Y_X is to be determined according to Table 3.14.3.

Size Factor of Bending Stress Y_X *Table 3.14.3*

Y_X	m_n	Status
1.00	$m_n \le 5$	Generally
$1.03 - 0.006\ m_n$	$5 < m_n < 30$	Normalized and through-hardened steels
0.85	$m_n \ge 30$	
$1.05 - 0.01\ m_n$	$5 < m_n < 25$	Surface hardened steels
0.80	$m_n \ge 25$	

3.15 Rim thickness factor, Y_B

The rim thickness factor, Y_B, is a simplified factor used to de-rate thin rimmed gears. For critically loaded applications, this method should be replaced by a more comprehensive analysis. Factor Y_B is to be determined as follows:

(1) for external gears: If

$S_R/h \ge 1.2$, $Y_B = 1$,

If $0.5 < \frac{S_R}{h} < 1.2$, $Y_B = 1.6 \cdot \ln(2.242\ \frac{h}{S_R})$

where: S_R — rim thickness of external gears, in mm;
h — tooth height, in mm.
The case $S_R/h \leq 0.5$ is to be avoided.

(2) for internal gears:
If $S_R/m_n \geq 3.5$, Y_B=1;
If $1.75 < S_R/m_n < 3.5$, $Y_B = 1.15 \cdot \ln(8.324 \frac{m_n}{S_R})$
where: S_R— rim thickness of internal gears, in mm.
The case $S_R/h \leq 1.75$ is to be avoided.

3.16 Deep tooth factor, Y_{DT}

The deep tooth factor, Y_{DT}, adjusts the tooth root stress to take into account high precision gears and contact ratios within the range of virtual contact ratio $2.05 \leq \varepsilon_{\alpha n} \leq 2.5$, where:

$$\varepsilon_{\alpha n} = \frac{\varepsilon_\alpha}{\cos^2 \beta_b}$$

Factor Y_{DT} is to be determined as follows:

If ISO accuracy grade ≤ 4 and $\varepsilon_{\alpha n} > 2.5$, $Y_{DT} = 0.7$;
If ISO accuracy grade ≤ 4 and $2.05 < \varepsilon_{\alpha n} \leq 2.5$, $Y_{DT} = 2.366 - 0.666 \cdot \varepsilon_{\alpha n}$; in all other cases, $Y_{DT} = 1.0$.

3.17 Safety factor for tooth root bending stress S_F

3.17.1 The safety factor for tooth root bending stress, S_F, can be assumed by taking into account the type of application. The safety factor for tooth root bending stress S_F is to comply with the following requirements:

main propulsion gears: $1.55 \leqslant S_F \leqslant 2.00$;
auxiliary gears: $1.40 \leqslant S_F \leqslant 1.45$.
For gearing of duplicated independent propulsion or auxiliary machinery, a reduced value can be assumed.

4 *Alignment*

4.1 Summary

At present, most gear box manufacturers require that during shaft alignment, static specific pressure of the gear bearing is not to exceed the specified value and static reaction difference of fore and aft bearings is not to exceed 20% of the total weight upon the two spans. Some manufacturers specify the dynamic limited pressure at the same time. It is proved through experience that under some circumstances, even if the conditions mentioned above are satisfied, the safety of the gearbox will not necessarily be ensured; on the contrary, even if the conditions mentioned above are not satisfied, it will not necessarily result in the failure of the gearbox. This covers design, alignment and installation of gearbox.

For gearbox is a part of the driving shafting, its alignment status is inevitably different with the different arrangement of shafting. Nevertheless, as a product, gearbox cannot be changed with the different arrangement of the shafting. The design of gearbox, such as arrangement of bearing, height of the bearing blocks, opening arrangement of sliding bearing pillow etc., is determined through dynamic resultant of gear force, so its safe operation when fitted onboard ship can be ensured.

4.2 Alignment calculation including gear force

4.2.1 The force of bearing in operation condition

When the gearbox is in static condition, only vertical static counterforce goes with the supporting bearing. Considering the influence of gearbox expansion in thermal state, the vertical static counterforce also goes with the supporting bearing. But when in operation condition, due to the influence of the gear force, not only supporting force changes, but the acting direction changes.

4.2.2 Calculation for dynamic resultants

Take the X-axis as along the gear shaft centerline, and the positive direction is from aft to fore wheel bearings. The Y-axis is perpendicular to the X-axis, with the upward direction as positive direction. The direction of Z-axis is determined by the right-hand rule.

Take the angle between the Y-axis and the line connecting gear engaged point and driven gear center as ψ, with the clockwise direction as positive direction.

θ_f and θ_a are angles between the Z-axis and the dynamic resultants on fore and aft bearings, with the counter-clockwise direction as positive direction.

L_1 is the distance between gear centerline and aft bearing; L_2 is the distance between gear centerline and fore bearing.

Take the upward direction (Y direction) as positive for counterforce on bearings; take the right direction (Z direction) as positive for counterforce on bearings while observed from aft to fore bearings.

Figure 4.2.2(1) shows the various forces that the final pinion with double gear ratio acts on wheel.

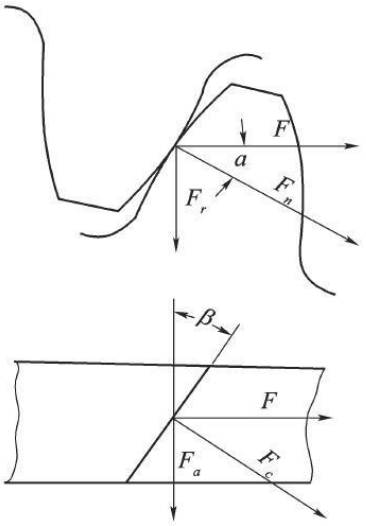

Figure 4.2.2(1) Forces acting on pinion

For spur gear and single helical gear, the dynamic resultants acting on bearings and acting directions are calculated in accordance with the following formulae:

(1) Counterforce which gear tangential force acts on fore and aft bearings

Tangential force F_t acting on wheel is:

$$F_t = 2T_1/d_1 \quad \text{kN} \tag{1}$$

where: T_1 — transmission torque acting on pinion, in N·m:

$$T_1 = 9550P\ u_2/n_e \tag{2}$$

where: P — propelling power transmitted by the reduction gear of the gearbox, in kW;

n_e — rated speed of the main engine, in r/min;

u_2 —gear ratio;

d_1 — working diameter of pinion, in mm.

The component of tangential force F_t acting on wheel in the Z direction, F_{tz}, is:

$$F_{tz} = F_t \cos\psi = 2T_1 \cos\psi/d_1 \quad \text{kN} \tag{3}$$

The component of tangential force F_t acting on wheel in the Y direction, F_{ty}, is:

$$F_{ty} = F_t \sin\psi = 2T_1 \sin\psi/d_1 \quad \text{kN} \tag{4}$$

The counterforce which gear tangential force acts on fore bearing in the Z direction, F_{tzf}, is:

$$F_{tzf} = \pm 2T_1\ L_1\cos\psi/((L_1+L_2)\ d_1) \quad \text{kN} \tag{5}$$

The counterforce which gear tangential force acts on aft bearing in the Z direction, F_{tza}, is:

$$F_{tza} = \pm 2T_1\ L_2\cos\psi/((L_1+L_2)\ d_1) \quad \text{kN} \tag{6}$$

The counterforce which gear tangential force acts on fore bearing in the Y direction, F_{tyf}, is:

$$F_{tyf} = \pm 2T_1\ L_1\sin\psi/((L_1+L_2)\ d_1) \quad \text{kN} \tag{7}$$

The counterforce which gear tangential force acts on aft bearing in the Y direction, F_{tya}, is:

$$F_{tya} = \pm 2T_1\ L_2\sin\psi/((L_1+L_2)\ d_1) \quad \text{kN} \tag{8}$$

Observed from aft to fore bearings, when the driven wheel rotates counter-clockwise, formulae (5) and (6) take positive, formulae (7) and (8) take negative; when it rotates clockwise, formulae (5) and (6) take negative, formulae (7) and (8) take positive.

(2) Counterforce which gear radial force F_r acts on fore and aft bearings

Radial force F_r is:

$$F_r = F_t \tan\alpha_n / \cos\beta \quad \text{kN} \tag{9}$$

where: α_n — normal engaged angle, in °.

β — helix angle at spur helical gear, in °.

The component of radial force F_r in the Z direction, F_{rz}, is:

$$F_{rz} = F_r \sin\psi = F_t \tan\alpha_n \sin\psi / \cos\beta \quad \text{kN} \tag{10}$$

The component of radial force F_r in the Y direction, F_{ry}, is:

$$F_{ry} = F_r \cos\psi = F_t \tan\alpha_n \cos\psi / \cos\beta \quad \text{kN} \tag{11}$$

The counterforce which gear radial force acts on fore bearing in the Z direction, F_{rzf}, is:

$$F_{rzf} = F_t L_1 \tan\alpha_n \sin\psi/((L_1 + L_2)\cos\beta) \quad \text{kN} \tag{12}$$

The counterforce which gear radial force acts on aft bearing in the Z direction, F_{rza}, is:

$$F_{rza} = F_t L_2 \tan\alpha_n \sin\psi/((L_1 + L_2)\cos\beta) \quad \text{kN} \tag{13}$$

The counterforce which gear radial force acts on fore bearing in the Y direction, F_{ryf}, is:

$$F_{ryf} = F_t L_1 \tan\alpha_n \cos\psi/((L_1 + L_2)\cos\beta) \quad \text{kN} \tag{14}$$

The counterforce which gear radial force acts on aft bearing in the Y direction, F_{rya}, is:

$$F_{rya} = F_t L_2 \tan\alpha_n \cos\psi/((L_1 + L_2)\cos\beta) \quad \text{kN} \tag{15}$$

(3) Counterforce which gear axial force F_a acts on fore and aft bearings

Axial force F_a is:

$$F_a = F_t \tan\beta \quad \text{kN} \tag{16}$$

The counterforce which gear axial force acts on fore bearing in the Z direction, F_{azf}, is:

$$F_{azf} = \pm F_t d_1 \tan\beta \sin\psi /(2(L_1 + L_2)) \quad \text{kN} \tag{17}$$

The counterforce which gear axial force acts on fore bearing in the Y direction, F_{ayf}, is:

$$F_{ayf} = \pm F_t d_1 \tan\beta \cos\psi /(2(L_1 + L_2)) \quad \text{kN} \tag{18}$$

For formulae (17) and (18), if, observed from aft to fore bearings, the wheel rotates counter-clockwise and is right-hand teeth, F_{azf} and F_{ayf} are positive; if the wheel rotates counter-clockwise and is left-hand teeth, F_{azf} and F_{ayf} are negative; if the wheel rotates clockwise and is right-hand teeth, F_{azf} and F_{ayf} are negative; if the wheel rotates clockwise and is left-hand teeth, F_{azf} and F_{ayf} are positive.

F_{aza}, the counterforce which gear axial force acts on aft bearing in the Z direction, and F_{azf} are equal in magnitude and opposite in direction; F_{aya}, the counterforce which gear axial force acts on aft bearing in the Y direction, and F_{ayf} are equal in magnitude and opposite in direction.

(4) Counterforce which gear weight acts on fore and aft bearings

The counterforce which gear weight acts on fore bearing, R_{f1}, is:

$$R_{f1} = 0.0098\ G_1 L_1 /(L_1 + L_2) \quad \text{kN} \tag{19}$$

The counterforce which gear weight acts on aft bearing, R_{a1}, is:

$$R_{a1} = 0.0098\ G_1 L_2 /(L_1 + L_2) \quad \text{kN} \tag{20}$$

where: G_1— gear weight, in kg.

(5) Counterforce which flange output shaft acts on fore and aft bearings

Case 1: if the center of gravity of flange output shaft is between the fore and aft bearings, then: the counterforce which flange output shaft acts on fore bearing, R_{f2}, is:

$$R_{f2} = 0.0098\ G_2 L_3 /(L_3 + L_4) \quad \text{kN} \tag{21}$$

the counterforce which flange output shaft acts on aft bearing, R_{a2}, is:

$$R_{a2}=0.0098\ G_2L_4/(L_3+L_4) \qquad \text{kN} \qquad (22)$$

where, for formulae (21) and (22),

G_2—weight of flange output shaft, in kg;

L_3 —distance between the gravity center of flange output shaft and the aft bearing, in mm;

L_4—distance between the gravity center of flange output shaft and the fore bearing, in mm.

Case 2: if the center of gravity of flange output shaft is on the left of (behind) the aft bearing, then: the counterforce which flange output shaft acts on fore bearing, R_{f2}, is:

$$R_{f2}=-0.0098G_2L_3/(L_4-L_3) \qquad \text{kN} \qquad (23)$$

the counterforce which flange output shaft acts on aft bearing, R_{a2}, is:

$$R_{a2}=0.0098G_2L_4/(L_4-L_3) \qquad \text{kN} \qquad (24)$$

Dynamic resultants F_f, F_a acting on fore and aft bearings and acting direction θ_f, θ_a is:

$$F_f=\left[(F_{tzf}+F_{rzf}+F_{azf})^2+(F_{tyf}+F_{ryf}+F_{ayf}+R_{f1}+R_{f2})^2\right]^{1/2} \qquad \text{kN} \qquad (25)$$

$$\theta_f=tg^{-1}\left[(F_{tyf}+F_{ryf}+F_{ayf}+R_{f1}+R_{f2})/(F_{tzf}+F_{rzf}+F_{azf})\right] \qquad (°) \qquad (26)$$

$$F_a=\left[(F_{tza}+F_{rya}+F_{aza})^2+(F_{tya}+F_{rya}+F_{aya}+R_{a1}+R_{a2})^2\right]^{1/2} \qquad \text{kN} \qquad (27)$$

$$\theta_a=tg^{-1}\left[(F_{tya}+F_{rya}+F_{aya}+R_{a1}+R_{a2})/(F_{tza}+F_{rya}+F_{aza})\right] \qquad (°) \qquad (28)$$

where:

F_{tzf}, F_{tza}— counterforce which gear tangential force acts on fore and aft bearings in the Z direction, in kN, see formulae (5) and (6);

F_{tyf}, F_{tya} — counterforce which gear tangential force acts on fore and aft bearings in the Y direction, in kN, see formulae (7) and (8);

F_{rzf}, F_{rza} — counterforce which gear radial force acts on fore and aft bearings in the Z direction, in kN, see formulae (12) and (13);

F_{ryf}, F_{rya}— counterforce which gear radial force acts on fore and aft bearings in the Y direction, in kN, see formulae (14) and (15);

F_{azf}, F_{aza}— counterforce which gear axial force acts on fore and aft bearings in the Z direction, in kN, see formula (17);

F_{ayf}, F_{aya}— counterforce which gear axial force acts on fore and aft bearings in the Y direction, in kN, see formula (18);

R_{f1}, R_{a1}— counterforce which gear weight acts on fore and aft bearings, in kN, see formulae (19) and (20);

R_{f2}, R_{a2}— counterforce which flange output shaft acts on fore and aft bearings, in kN, see formulae (21), (22), (23) and (24);

F_f,F_a — dynamic resultants on fore and aft bearings, in kN;

θ_f, θ_a — acting angle of dynamic resultants on fore and aft bearings (°)

Obviously, due to the influence of gear force, under operation condition, dynamic resultants of fore and aft bearings of wheels and its acting direction are different from force of alignment calculation for shafting thermal state and its direction.

Dynamic resultants F_f, F_a acting on fore and aft bearings and acting direction θ_f, θ_a is:

$$F_f = \left[(F_{tzf})^2 + (F_{ryf} + F_{ayf} + R_{f1} + R_{f2})^2\right]^{1/2} \quad \text{kN} \quad (29)$$

$$\theta_f = \tan^{-1}\left[(F_{ryf} + F_{ayf} + R_{f1} + R_{f2})/F_{tzf}\right] \quad (°) \quad (30)$$

$$F_a = \left[(F_{tza})^2 + (F_{rya} + F_{aya} + R_{a1} + R_{a2})^2\right]^{1/2} \quad \text{kN} \quad (31)$$

$$\theta_a = \tan^{-1}\left[(F_{rya} + F_{aya} + R_{a1} + R_{a2})/F_{tza}\right] \quad (°) \quad (32)$$

where:

$$F_{tzf} = \pm 2T_1 L_1/((L_1+L_2)\, d_1) \quad \text{kN} \quad (33)$$

$$F_{tza} = \pm 2T_1 L_2/((L_1+L_2)\, d_1) \quad \text{kN} \quad (34)$$

$$F_{ryf} = F_t L_1 \tan\alpha_n/((L_1 + L_2)\cos\beta) \quad \text{kN} \quad (35)$$

$$F_{rya} = F_t L_2 \tan\alpha_n/((L_1 + L_2)\cos\beta) \quad \text{kN} \quad (36)$$

$$F_{ayf} = -F_{aya} = \pm F_t d_1 \tan\beta\cos\psi/(2(L_1 + L_2)) \quad \text{kN} \quad (37)$$

If the pinion is right above the wheel, then:

Figure 4.2.2(2) shows the counterforce on fore and aft wheel bearings when the pinion is right above the wheel.

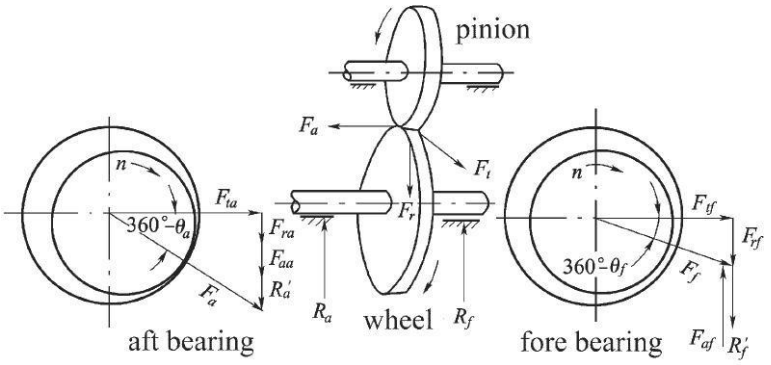

Figure 4.2.2(2) Counterforce on the wheel bearings

4.3 Influence of dynamic resultant

4.3.1 The interface of gear pillow is to be arranged in accordance with dynamic resultant direction.

(1) Bearing arrangement of straight tooth gear shaft

It may be seen from 4.2.2 that if it is straight tooth gear, there is no axial force, i.e., $F_a = 0$, then under the condition that bearing span is same or close, dynamic resultant and its direction is determined by the counterforce of shafting alignment and its direction. Where the counterforce of fore and aft bearings of delivery gear through alignment of shafting is positive value and is less than 20%, dynamic resultant of the two bearings and its direction is basically the same, and gear shaft will not be distorted. But due to the act of tangential force of gear, the direction of dynamic resultant is not on the vertical position, but within the IV quadrant (when the shaft rotates clockwise), as shown in Figure 4.3.1(1). Therefore, in order to ensure the establishment of lubricant film of bearing, and to avoid scorification of pillow, consideration is to be taken for the correct position of pillow entering oil groove, i.e., the interface of pillow is to be turned counter-clockwise to about 70° to 100° in accordance with the position of dynamic resultants.

(2) Bearing arrangement of helical gear shaft

For helical gear, $F_a \neq 0$, the strength and direction of dynamic resultant of fore and aft bearings are different, especially, the change of acting direction is great as shown in Figure 4.3.1(2). In this case, gear shaft will be distorted. Simultaneously, in order to ensure the normal establishment of lubricant film of bearing, and to avoid scorification of pillow, the position of dynamic resultants is to be calculated separately, and the interface of pillow is to be turned counter-clockwise to about 70° to 100°.

(3) Gear shafts other than delivery gear shaft

Where sliding bearings are adopted for other bearings in driving gears, the counter force of each bearing and gear force is to be calculated, and then dynamic resultant and direction of each bearing is to be calculated. The interface of pillow is also to be turned counter-clockwise to about 70° to 100° in accordance with the position of dynamic resultants.

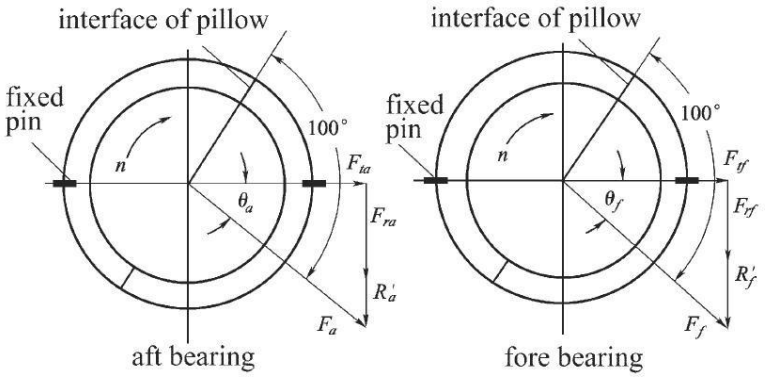

Figure 4.3.1(1) Stress of fore and aft bearings of spur gear

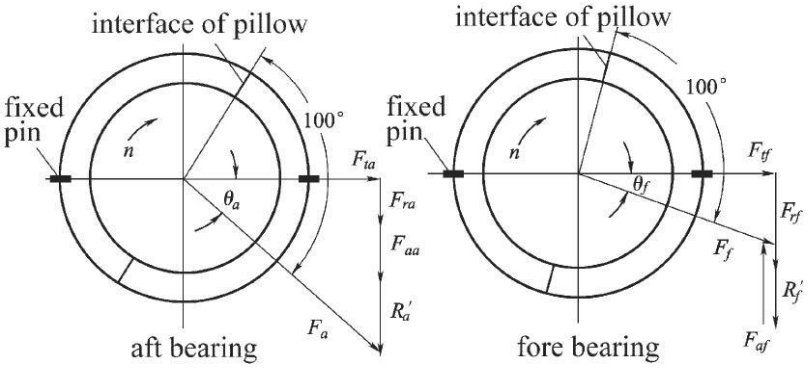

Figure 4.3.1(2) Stress of fore and aft bearings of helical gear

4.3.2 After the interface of pillows is determined according to the dynamic resultant, the counter force difference of alignment of two bearings may not be limited by 20% of the total weight.

When the driving shafting of gear is being aligned, the required load difference of fore and aft bearing of delivery gear is to be as little as possible. The maximum is not to exceed 20% of the total weight of the gear and shaft. Actually, if the interface of the gear pillow is determined in accordance with the dynamic resultant direction, the strength and direction of the dynamic resultant are mainly determined by the gear force under the condition that the alignment counterforce of two bearings is positive value (i.e., non-straight-line alignment). Therefore, during actual installation of shafting, it is safe even if the counter force difference of two bearings exceeds 20%. If the alignment counterforce of the fore bearing of delivery gear shaft on a ship is 28.95 kN, and the counterforce of the aft bearing is 10.61 kN, the difference is 2.7 times which greatly exceeds the defined 20%. However, the dynamic resultant of the fore bearing turns from 235 kN to 237 kN, and its acting angle turns from 348.2° to 346.4°; while the dynamic resultant of aft bearing turns from 283 kN to 277 kN, and its acting angle turns from 324.3° to 326.2°. Obviously, though the alignment counterforce difference of fore and aft bearing exceeds greatly the defined 20%, the influence of dynamic resultant and acting angle is little, i.e., the influence to dynamic specific pressure of the bearings and establishment of oil film is little, which is still safe.

4.3.3 Reducing the included angle of the dynamic resultants of fore and aft bearings can strengthen the engaging capability of gears and reduce noise.

The greater the included angle between dynamic resultant of fore and aft bearings, the greater the distorted angle of gear shaft; then the gear is distorted, which results in uneven contact along the facewidth, reducing the bearing capacity and increasing the contact stress of the gear. It will cause single side wearing of the gear, and even cause the gear broken event. Therefore, to ensure the parallel of the gear shaft, strengthen the engaging capability of gears and reduce noise, the included angle of the dynamic resultants of fore and aft bearings is to be reduced as far as possible. For driving shafting of the helical gear when it is being designed, the greater static counterforce value of the fore bearing is to be taken, so as to offset the influence of counterforce F_{af} of the axial force F_a acting upon the fore bearing.

In order to reduce the included angle of the dynamic resultants of fore and after bearing, when the gear is being designed, the F_a value is to be reduced as far as possible or $F_a = 0$, which may be achieved by the arrangement of herringbone gears, planetary gears or the symmetric arrangement of gears.

4.4 Alignment requirements to shafting

4.4.1 Parameters needed for alignment calculation of shafting

In order to facilitate alignment calculation of shafting, gearbox manufacturer is to provide following parameters:

Manufacturer:
Type:
Rated power: in kW
Rated speed: in r/min
Gear ratio:
Working diameter of pinion: in mm
Working diameter of wheel: in mm
Helix angle β of spur helical pinion, wheel: (°)
Normal engaged angle α_n: (°)
Structural size of pinion, wheel: in mm

Type of bearing:
Length of sliding bearing pillow: in mm
Open corner of sliding bearing pillow: (°)
Angle between the Y-axis and the line connecting gear engaged point and driven gear center ψ
Distance between gear centerline and fore bearing L_1
Distance between gear centerline and aft bearing L_2

4.4.2 The requirements to be satisfied for shafting alignment

(1) Rolling bearings

For rolling bearings, there is no need for establishment of lubricant film and the influence of gear force is considered during design, shafting alignment after the ship is loaded is to satisfy the following requirements:

① static load or dynamic load of bearing is not to exceed the permissible value;

② static counterforce difference or dynamic counterforce difference of fore and aft bearings is not to exceed the permissible value.

(2) Sliding bearings

For sliding bearings, due to establishment of lubricant film, if the gear force is included in design according to the requirements of this Chapter, shafting alignment after the ship is loaded is to satisfy the following requirements:

① not to exceed the dynamic specific pressure value of the bearing allowed for gearbox;

② changing of dynamic resultants not to affect the establishment of the lubricant film of gear bearing.

CHAPTER 11 SHAFTING AND PROPELLERS

Section 1 GENERAL PROVISIONS

11.1.1 *Application*

11.1.1.1 This Chapter is applicable to the shafting of ships propelled by diesel engines, steam turbines, gas turbines or electric propelling motors.

11.1.2 *General requirements*

11.1.2.1 Where the couplings are separate from the thrust shafts, intermediate shafts, tube shafts (i.e. the shaft which passes through the stern tube, but does not carry the propeller) and screwshafts, provision is to be made for the couplings to resist the astern pull so that no axial displacements of the couplings relative to the shafts may occur. Excessive stress concentration on the shafts is to be avoided.

11.1.2.2 Materials for shafting and propellers are to comply with the relevant requirements of ISC Rules for Materials and Welding.

The specified tensile strength of forgings for shafts is to be selected within the following general limits:

(1) for carbon and manganese steel, 400 to 760 N/mm^2. Where shafts may experience vibration stresses exceeding 90% permissible stresses for transient operation, the materials are to have a specified minimum ultimate tensile strength of 500 N/mm^2;

(2) for alloy steel, not exceeding 800 N/mm^2.

If the specified tensile strength exceeds the limitation value in 11.1.2.2(1) and (2) of this Chapter, calculation of shaft diameter is to comply with the provisions in 11.2.2.1 of this Chapter and calculation of permissible vibration stress is to comply with the provisions in 12.2.3.3, Chapter 12 of this PART.

For shaft couplings, nodular graphite cast iron may also be accepted.

11.1.2.3 The main propulsion shafting together with its transmission gears are to be capable of withstanding sufficient astern power.

For the main propulsion shafting with reduction gears, controllable pitch propellers or electric propelling motors, running astern are not to lead to the overload of main engines.

11.1.2.4 The sliding bearing temperature in the main propulsion shafting and transmission gearing is not to exceed 70℃, and not to exceed 80℃ if roller bearing is fitted.

11.1.2.5 The certificate requirements and product survey of shaft, bearing, coupling, propeller, transverse propulsion arrangement, Z propulsion arrangement and shafting connecting bolt are to comply with relevant requirements in Chapter 3, PART ONE of the Rules.

11.1.2.6 Alternative calculation methods may be considered by ISC. Any alternative calculation method is to include all relevant loads on the complete dynamic shafting system under all permissible operating conditions. Consideration is to be given to the dimensions and arrangements of all shaft connections. Moreover, an alternative calculation method is to take into account design criteria for continuous and transient operating loads (dimensioning for fatigue strength) and for peak operating loads (dimensioning for yield strength). The fatigue strength analysis may be carried out separately for different load assumptions, for example as given in Section 2 of Chapter 11 and Section 2 of Chapter 12.

11.1.3 *Vibration and Alignment of Shafting*

11.1.3.1 The shafting is also to comply with the requirements for shafting vibration and alignment in Chapter 12 of this PART.

11.1.4 *Plans and documents*

11.1.4.1 The following plans and documents of shafting and propellers are to be submitted for approval:

(1) Arrangement of Shafting;

(2) Thrust shaft, intermediate shaft, tube shaft (where applicable), and screwshaft;

(3) General arrangement of stern tube, including oil sealing gland and tube shaft bearings;

(4) Strength calculations for shafting, including calculations for the connection of couplings and strength calculations of bolts;

(5) Strength calculations for propellers;

(6) Propeller (including the clearances between the propeller and hull etc.);

(7) Oil shrink fitting of key or keyless propeller together with calculations (where applicable).

11.1.4.2 Detailed sizes and necessary parameters for verifying the calculations are to be indicated in plans.

Section 2 SHAFTING

11.2.1 *General requirements*

11.2.1.1 The minimum diameter of shafts determined by the formulae in this Section is to be checked for the allowable torsional vibration stress as specified in Chapter 12 of this PART.

11.2.2 *Diameter of shafts*

11.2.2.1 Low cycle fatigue criterion (typically < 10^4), i.e. the primary cycles represented by zero to full load and back to zero, including reversing torque if applicable.

The shaft diameter d is not to be less than the value determined by the following formula:

$$d = FC \sqrt[3]{\frac{N_e}{n_e}\left(\frac{560}{R_m + 160}\right)} \quad \text{mm}$$

where: F — factor for the type of propulsion installation:

F= 95 for intermediate shafts in turbine installations, diesel installations with hydraulic (slip type) couplings, electric propulsion installation;

F= 100 for all other diesel installations and all propeller shafts;

C — factor for the particular shaft design features (see Table 11.2.2.1) or calculated in accordance with the following formula;

$$C = \left[\frac{scf}{1.45}\right]^x$$

x — low cycle notch sensitivity. The chosen values are mainly representative for soft steels (R_m < 600), while the influence of steep stress gradients in combination with high strength steels may be underestimated;

scf — the stress concentration factors relative to the stress concentration for a flange with fillet radius of 0.08d (geometric stress concentration of approximately 1.45);

N_e — rated power transmitted through the shaft, in kW;

n_e — speed in revolution per minute of shaft at rated power, in r/min;

R_m — specified tensile strength of shaft material, in N/mm^2. For intermediate shaft, when carbon and manganese steel is used, it is to be taken as 760 N/mm^2 for R_m> 760 N/mm^2; when alloy steel is used, it is to be taken as 800 N/mm^2 for R_m> 800 N/mm^2. For special approval of alloy steel used for intermediate shaft material, the tensile strength of shaft material may be greater than 800 N/mm^2, but less than 950 N/mm^2, where such approval of the material comply with the relevant requirements for torsional fatigue test①, cleanliness②and inspection. The requirements of 5.1.1.1, 5.3.2.1, 5.3.2.3 and 5.3.4.5 for the cleanliness of material, and the requirements of 5.1.6 for the inspection in Chapter 5, PART ONE of ISC Rules for Materials and Welding are to be complied with. For screwshaft and tube shaft, it is to be taken as 600 N/mm ^{2} for R_m> 600 N/mm^2.

Factor C for different design features *Table 11.2.2.1*

Intermediate shafts with					Thrust shafts external to engines		Propeller shafts		
Integral coupling flange	Keyless couplings fitted by oil shrink method	keyway	Radial hole	Longitudinal slot	The portion of thrust shafts outside the thrust collar at a length equal to the thrust shaft diameter, the remainder may be tapered down to the diameter required for the intermediate shaft	In way of axial bearings where roller bearing is used as thrust bearing	Flange mounted or keyless taper fitted propeller shafts	Key fitted propeller shafts	The portion of the screwshaft and tube shaft forward of the length of screwshaft required by 11.2.2.3 till it reaches the aft peak bulkhead
1.0①	1.0⑦	1.10②⑤⑧	1.10③⑤	1.20④⑤	1.10	1.10	1.22	1.26	1.15

① Torsional fatigue test is to meet the requirements of 7.4.6 of Guidelines for Inspection of Forged Steel.

② Cleanliness is to meet the requirements of 7.4.6 of Guidelines for Inspection of Forged Steel.

Notes:

① The fillet radius at the base of the flange is not to be less than 0.08*d*.

② For over a length of at least 0.2*d* of the shaft from the ends of keyway and, the diameter of the shaft is to be increased by taking C = 1.10. The diameter of the shaft is to be decreased by taking C = 1.0 for the range beyond. The fillet radius in the transverse section at the bottom of the keyway are not to be less than 0.0125*d*.

③ For over a length of at least 0.2*d* of the shaft from the ends of hole and, the diameter of the shaft is to be increased by taking C = 1.10. The diameter of the shaft is to be decreased by taking C = 1.0 for the range beyond. The diameter of the hole is not to be greater than 0.3*d*. The intersection between a radial and an eccentric axial bore is not applicable, as shown in the figure below.

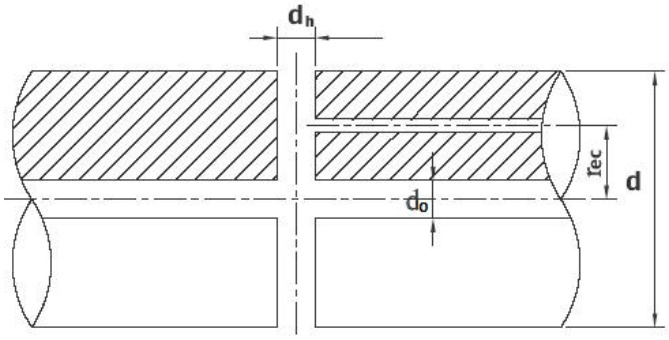

Figure 11.2.2.1 Intersection Between a Radial and an Eccentric Axial Bore

④ For over a length of at least 0.3*d* of the shaft from the longitudinal slot and its ends, the diameter of the shaft is to be increased by taking C = 1.20. The diameter of the shaft is to be decreased by taking C = 1.0 for the range beyond. In general, slot length is to be less than 0.8*d*, width is to be more than 0.15*d* and inner diameter is to be less than 0.7*d*. The end rounding of the slot is not to be less than half of the slot width and the quantity of slot is not to be more than 3. Slots at respectively 180º apart for 2 slots, and slots at respectively 120º apart for 3 slots. An edge rounding is preferably to be avoided as this increases the stress concentration slightly.

⑤ For shaft having several design features, the factor is to be the product of several factors.

⑥ Where, *d* is calculated with C = 1.0.

⑦ Where shafts may experience vibratory stresses exceeding 90% the permissible stresses for continuous operation, an increase in diameter to the shrink fit diameter is to be provided, e.g. a diameter increase of 1 to 2%.

⑧ Keyways are in general not to be used in installations with a barred speed range.

11.2.2.2 Screwshafts or tube shafts forward of the aft peak bulkhead may be gradually reduced to the diameter of the intermediate shaft.

11.2.2.3 The diameter of the screwshaft determined in accordance with the formula in 11.2.2.1 is to extend over a length not less than that to the forward edge of the bearing immediately forward of the propeller or 2.5 times the diameter of the screwshaft, whichever is the greater.

11.2.2.4 Transitions of diameters are to be designed with either a smooth taper or a blending radius. For guidance, a blending radius equal to the change in diameter is recommended.

11.2.3 *Hollow shafts*

11.2.3.1 For shafts where the bore d_0 is greater than 0.4*d*, the actual external diameter d_a of the shaft is not to be less than that determined by the following formula:

$$d_a = d\sqrt[3]{\frac{1}{1-\left(\frac{d_0}{d_a}\right)^4}} \quad \text{mm}$$

where: *d* — shaft diameter determined by 11.2.2.1 of this Section, in mm;

d_0— actual bore of the shaft, in mm.

11.2.3.2 The edges of slots and holes in the shafts are to be smooth and without any traces of machining.

11.2.3.3 For ships engaged only in harbor service, the minimum diameter of the shafts may be reduced by 3%.

11.2.4 *Shaft liners*

11.2.4.1 The thickness *t* of bronze shaft liners shrunk on tube shafts or screwshafts, in way of the bushes, is not to be less than:

$$t = 0.03d + 7.5 \quad \text{mm}$$

where: *d* — diameter of tube shaft or screwshaft in way of the bushes, in mm.

The thickness of stainless steel liners, where fitted, is to be one-half that obtained above, but not less than 6

mm.

11.2.4.2 The thickness of a continuous liner between the bushes may be somewhat reduced, but is not to be less than 0.75*t*.

11.2.4.3 Continuous liners are to be generally cast in one piece. Where necessary, they may consist of two or more pieces, but these are to be butt-welded by reliable methods to prevent water ingress.

11.2.4.4 Where the portion of the shaft between any two lengths of the liner is protected with glass-reinforced plastics or other industrial plastics, the protection at the junction of the liner ends is to be of such a construction as to prevent the shaft from water ingress. In general, semicircular groove may be at the junction of the liner ends which is protected with several layers of glass-reinforced plastics or other industrial plastics and secured with copper wire or stainless steel wire. The connection portions are not to be located within the bearing range.

11.2.4.5 Shaft liners which are cast in one piece or consist of two or more lengths, are to be subject to hydraulic test to a pressure of 0.2 MPa after rough machining, and there is to be no crack or leakage.

11.2.4.6 Liners are to be carefully shrunk on, or forced on, to the shafts by hydraulic pressure. Pins are not to be used to secure the liners.

11.2.4.7 Effective means are to be provided for preventing water from reaching the shaft at the part between the after end of the liner and the propeller boss.

11.2.5 *Stern tubes and bearings*

11.2.5.1 The length of the bearing in the stern bush next to and supporting the propellers is to be as follows:

(1) For water lubricated bearings, the length of the bearing is not to be less than 4 times the rule calculated diameter for the screwshaft in way of the bearing. For water lubricated synthetic materials, if the design and materials of bearings comply with ISC provisions as demonstrated by tests, the length of the bearings may be appropriately reduced, but not less than 2 times the rule diameter of the shaft in way of the bearing. Synthetic materials of water lubricated stern tube bearings are to be type approved.

(2) For bearings which are white-metal lined and oil lubricated, the length of the bearing is not to be less than twice the rule calculated diameter for the screwshaft in way of the bearing. If the normal bearing pressure is less than 0.8 MPa as determined by static bearing reaction calculation taking into account shaft and propeller weight, the length of the bearings may be appropriately reduced. However, the minimum length is to be not less than 1.5 times the actual diameter.

(3) For bearings of synthetic rubber, reinforced resin or plastics materials which are approved for use as oil lubricated stern bush bearings, the length of the bearing is to be not less than twice the rule diameter of the shaft in way of the bearing. If the normal bearing pressure is less than 0.6 MPa as determined by static bearing reaction calculation taking into account shaft and propeller weight, the length of the bearings may be appropriately reduced. However, the minimum length is to be not less than 1.5 times the actual diameter. Synthetic materials for application as oil lubricated stern tube bearings are to be Type Approved.

Where the material has proven satisfactory testing and operating experience, consideration may be given to an increased bearing pressure.

(4) The length of a grease lubricated bearing is to be not less than 4.0 times the rule diameter of the shaft in way of the bearing.

(5) For bearings which are lined with other materials or lubricated by other methods, background for adopting its bearing length is to be provided, e.g. test results such as expansion characteristics and bearing capability of bearing material or service experience.

11.2.5.2 Forced water lubrication is to be provided for all bearings lined with rubber or plastics and for those lined with lignum vitae where the shaft diameter is 400 mm or over. A shut-off valve or cock controlling the supply of water is to be fitted direct to the after peak bulkhead or to the stern tube where the water supply enters the stern tube forward of the bulkhead.

11.2.5.3 Bearings which are oil lubricated are to be fitted with an approved oil sealing gland.

11.2.5.4 Where a gravity tank supplying lubricating oil to the stern bush is fitted, it is to be located above the load waterline and is to be provided with a low level alarm device in the engine room.

11.2.5.5 Where stern bush bearings are oil lubricated, provision is to be made for cooling the oil by maintaining water in the after peak tank above the level of the stern tube or by other suitable means.

11.2.5.6 Stern tubes are to be subject to hydraulic test to a pressure of 0.2 MPa before being fitted on board ship.

Section 3 SHAFT TRANSMISSION UNITS

11.3.1 *Application*

11.3.1.1 The requirements of this Section apply to couplings, hydraulic transmission arrangements, clutches, Z propulsion arrangement, transverse propulsion arrangement (if applying for additional notation) as well as controllable pitch propeller blade actuators. For transmission gearing, see Chapter 10 of this PART.

11.3.2 *Couplings*

11.3.2.1 Flange couplings are to comply with the following requirements:

(1) The thickness of coupling flanges is not to be less than 20% of the intermediate shaft diameter required in 11.2.2.1 of this Chapter, nor is it to be less than the diameter of the fitting coupling bolts whose minimum tensile strength is equivalent to that of the shafts. The fillet radius at the base of the coupling flange is not to be less than 8% of the actual diameter of the shaft at the coupling. Special consideration will be given for flanges having non-parallel faces, but in no case is the thickness of the flange to be less than the coupling bolt diameter.

(2) Where the propeller is attached to the screwshaft by means of a coupling flange, the thickness of the flange is not to be less than 25% of the actual diameter of the adjacent part of the screwshaft. The fillet radius at the base of coupling flange is not to be less than 12.5% of the actual diameter of the shaft at the coupling.

(3) Fillets are to have a smooth finish and not to be recessed in way of nuts and bolt heads. The fillet may be formed of multiradii in such a way that the stress concentration factor is not to be greater than that for a circular fillet with radius 0.08 times the actual shaft diameter.

11.3.2.2 Where the coupling is fitted to the shaft with a key and the torque is transmitted through the key, the effective sectional area of the key in shear is not to be less than that determined by the following formula, and the tensile strength of the key material is to be equal to or greater than that of the shaft material:

$$BL \geq \frac{d^3}{2.6 d_m} \qquad \text{mm}^2$$

where: B — breadth of key, in mm;

L — effective length of key, in mm;

d — diameter of intermediate shaft determined in 11.2.2.1 of this Chapter, in mm;

d_m — diameter of shaft at mid-length of the key, in mm.

11.3.2.3 Keyless couplings fitted by oil shrink method are to meet the following requirements:

(1) Muff couplings are to have a capacity of transmitting a torque which is 2.8 times the mean torque and their equivalent stress of the maximum shrinkage allowance is not to be more than 70% of the yield stress of the muff material.

(2) For general couplings which are not covered in (1) above, the pull-up S or shrinkage allowance $\delta$is to meet the following requirements:

$$S_1 \leq S \leq S_2 \qquad \text{mm}$$

$$\delta_1 \leq \delta \leq \delta_2 \qquad \text{mm}$$

$$S_1 = \frac{\delta_1}{K} = \frac{1}{K}\left[\frac{1672 N_e}{A n_e}(c_1 + c_2) + 0.03\right] \qquad \text{mm}$$

$$S_2 = \frac{\delta_2}{K} = \frac{0.034 \times 10^{-4}}{K} \mathrm{R}_{eH} d_1 (c_1 + c_2) \frac{K_2^2 - 1}{\sqrt{3K_2^4 + 1}} \qquad \text{mm}$$

where: S_1 — minimum axial pull-up, in mm;

S_2 — maximum axial pull-up, in mm;

δ_1 — minimum shrinkage allowance, in mm;

δ_2 — maximum shrinkage allowance, in mm;

K — taper of the shaft for shrink-fit;

N_e — rated power transmitted by the shaft, in kW;

n_e — speed of the shaft at N_e, in r/min;

A — theoretical contact area of the shrinkage surface, in mm^2;

$c_1 = \frac{1 + K_1^2}{1 - K_1^2} - \mu_1$;

$$c_2 = \frac{K_2^2 + 1}{K_2^2 - 1} + \mu_2;$$

$$K_1 = \frac{d_0}{d_1};$$

$$K_2 = \frac{d_2}{d_1};$$

d_0 — bore diameter of the shaft, in mm;
d_1 — mean diameter of the shaft within the contact length, in mm;
d_2 — mean outside diameter of the coupling within the contact length, in mm;
$\mu_1 = \mu_2 = 0.3$;
R_{eH} — specified yield stress of the coupling material, in N/mm^2.

11.3.2.4 Clamp couplings are to meet the following requirements:
(1) Clamp couplings are to have a strength at least equal to the required strength of the intermediate shaft.
(2) The clamp coupling is to be provided with a key. For couplings transmitting thrust, a satisfactory axial locking device is to be provided.
(3) Torque is to be transmitted by the frictional moment resulting from clamping and the key. The frictional moment is not to be less than the rated torque to prevent track slip and the sizes of the key are not to be less than 2/3 of those determined by the formula in 11.3.2.2.
(4) The clamping length of the coupling is normally to be at least 2.4 times shaft diameter.
11.3.2.5 Where other types of couplings or connections are used for torque transmission, background of test results or service experience are to be provided for the purpose of examining their reliability.

11.3.3 *Coupling bolts*

11.3.3.1 For intermediate, thrust and propeller shaft couplings having all fitted coupling bolts, the coupling bolt diameter d_f is not to be less than that given by the following formula:

$$d_f = 0.65\sqrt{\frac{d^3(R_m + 160)}{DZR_{mb}}} \quad \text{mm}$$

where: d — Rule diameter of the solid intermediate shaft, in mm, in accordance with the requirements of Chapter 14 of this PART, taking into account ice strengthening requirements where applicable;
Z — number of bolts;
D — pitch circle diameter, in mm;
R_m — tensile strength of the intermediate shaft material for calculation, in N/mm^2;
R_{mb} — tensile strength of the fitted coupling bolts material taken for calculation, in N/mm^2, where: $R_m \le R_{mb} \le 1.7\ R_m$, but not higher than 1,000 N/mm^2.

11.3.3.2 Where it is proposed to use non-fitting bolts for connections, the diameter d_n at the root of thread of the bolts is not to be less than that determined by the following formula:

$$d_n = 25\sqrt{\frac{N_e \times 10^6}{n_e DZR_{mb}}} \quad \text{mm}$$

where: N_e — rated output transmitted by the shaft, in kW;
n_e — speed of the shaft at N_e, in r/min;
other symbols are as defined in 11.3.3.1 of this Section.
The prestressing force and workmanship of ordinary bolts are to be provided for information.

11.3.3.3 Bolts connecting propellers and screwshafts are to be fitting bolts, the diameter of which is to be increased by 5% of that determined in 11.3.3.1 of this Section.
11.3.3.4 For ships engaged only in harbour service, the diameter of the connecting bolts may be reduced by 4%.
11.3.3.5 The diameter of the fitting bolts at the joining faces of the couplings within the crankshaft and thrust shaft/crankshaft is to be increased by 5% of that determined by 11.3.3.1 of this Section.

11.3.4 *Clutches and control devices*

11.3.4.1 The friction elements of clutches for reversible gearing are not to give any slip in normal running. While the clutch is disengaged, the propulsion shafting is not to be dragged along by the driving shaft.
11.3.4.2 The maximum torque transmitted by the clutch is, in general, not to be less than 1.5 times the

rated torque of the main engine.

11.3.4.3 The flexible clutches controlled by air pressure are to be provided with air charging pressure gauges, signal devices for indicating clutching and declutching of the clutches and alarm devices for giving warning of high and low air pressures.

11.3.4.4 An emergency device for air charging is to be fitted to the system which supplies air to the pneumatic flexible clutch.

11.3.4.5 For reversible clutches, the time required for reversal is not to be more than 15 s.

11.3.4.6 In single screw ships having clutches, emergency mechanical means are to be provided to ensure that the ship can run at a reasonable speed in the event of failure of the clutches.

11.3.5 *Hydraulic transmissions*

11.3.5.1 In single screw ships having emergency mechanical means are to be provided to ensure that the ship can run at a reasonable speed in the event of failure of the hydraulic transmission systems.

11.3.5.2 The lubricating oil system of hydraulic transmission arrangements is to be separate from other systems. The system is to consist of filters, coolers, drain tanks, etc. In the case of hydraulic gear transmission, in addition, magnetic filters are to be provided in the system.

11.3.5.3 Hydraulic transmission arrangements are to be provided with separate stand-by pumps. For propulsion systems with twin-engine and twin-screw, one stand-by pump may be accepted.

11.3.5.4 In addition to thermometers and pressure gauges, the lubricating oil system of hydraulic transmission arrangements is to be fitted with alarm devices for giving warnings of an excessive temperature and appreciable reduction in pressure of the oil supply.

11.3.5.5 The runners and impellers of hydraulic couplings are to be statically balanced. Furthermore, it is recommended that the runners and impellers be dynamically balanced.

11.3.5.6 Signal devices for indicating oil charging and discharging are to be fitted at the control positions of hydraulic transmission arrangement.

11.3.5.7 The hydraulic transmission arrangements may be controlled at the engine side and in the centralized control station or in the bridge. Where two or more control devices are fitted, they are to be interlocked one another.

11.3.5.8 In the case of multiple engines operating on one screwshaft, an interlocking device is to be provided in the control gear of the hydraulic transmission arrangement to prevent them from being filled with oil when the engines are in opposite directions.

11.3.5.9 At the centralized control station of hydraulic transmission, a tachometer showing the speed of the screwshaft and an indicator showing the direction of its rotation are to be fitted.

11.3.6 *Transmission devices for controllable pitch propeller*

11.3.6.1 The hydraulic transmission system of controllable pitch propeller blade actuators is to be provided with a separate stand-by pump having a capacity of not less than that required for power hydraulic oil pump during normal operation of one hydraulic transmission system of controllable pitch propeller. One independent stand-by pump may be common to hydraulic transmission system of controllable pitch propeller of duplicated propulsion shafting system. Where each hydraulic transmission system of controllable pitch propeller is provided with independent hydraulic pump, a complete spare pump may be accepted, provided that it is readily accessible and can easily be installed.

For propulsion plants up to 200 kW, one power-driven pump set is sufficient provided that, in addition, a hand-operated pump is fitted for controlling the blade pitch and that this enables the blades to be moved from the ahead to the astern position in a short enough time.

11.3.6.2 Pitch angle indicators are to be fitted both at the engine room control station and in the bridge. The deviation from the actual pitch angle is not to exceed ±1°.

11.3.6.3 The control system in the engine room is to be interlocked with that in the bridge. For control systems other than those actuated by mechanical devices, a stand-by manual control is to be fitted at the engine side.

11.3.6.4 The control system of hydraulic controllable pitch propeller blade actuators is to be such that the blade pitch can be altered efficiently and accurately.

11.3.6.5 Under any working conditions, the blade position of controllable pitch propellers is to be stable. Its fluctuation at 0° pitch angle is not to exceed ±0.5°.

11.3.6.6 At the rated speed of the propeller, the time required for the change of pitch angle from 1/3 positive maximum (or 1/3 negative maximum) to 1/3 negative maximum (or 1/3 positive maximum) is not to exceed 15 s.

11.3.6.7 The pitch adjusting range of controllable pitch propeller is to ensure that the main engine will provide rated power under rated speed and specified astern power.

11.3.6.8 Thread core diameter d_k of blade fastening bolts is not to be less than the value obtained from following formula:

$$d_k = 2.6\sqrt{\frac{W_{0.35R}R_{P0.2}\alpha_A}{dZR_{eH}}} \quad \text{mm}$$

where: $W_{0.35R}$ — section modulus of cylindrical section at radius 0.35R, in mm^3;

$$W_{0.35R} = 0.11\,(Bt^2)_{0.35R}$$

where: B — breadth of blade on section at radius 0.35R, in mm;

t — maximum thickness of blade on section at radius 0.35R, in mm.

$R_{P0.2}$ — 0.2% proof stress of propeller material, in N/mm^2;

α_A — tightening factor for retaining bolts, = 1.2 to 1.6, depending on the method of tightening used;

d — diameter of pitch circle of bolt hole of fastening bolts, in mm;

Z — number of bolts;

R_{eH} — yield strength of fastening bolts, in N/mm^2.

11.3.6.9 Under following conditions, the controllable pitch propeller is to have alarm function:

(1) pressure of hydraulic system is too low;

(2) oil level of main hydraulic oil tank is too low;

(3) oil filter is blocked;

(4) pressure of boss lubricating oil is too low (except for grease lubricating method);

(5) temperature of hydraulic oil is too high;

(6) pitch adjusting function fails;

(7) power supply of control system fails.

11.3.6.10 Suitable devices are to be fitted to ensure that an alteration of the blade setting cannot overload the propulsion plant or cause it to stall.

11.3.6.11 Steps are to be taken to ensure that, in the event of failure of the control system, the setting of the blades does not change or assumes a final position slowly enough to allow the emergency control system to be put into operation.

11.3.6.12 Controllable pitch propeller systems are to be equipped with means of emergency control enabling the controllable pitch propeller to remain in operation should the remote control system fail. It is recommended that a device be fitted which locks the propeller blades in the “ahead” setting.

In case of emergent fixed propeller condition, effective measures are to be provided to prevent pitch adjustment.

11.3.6.13 Before being installed on board, the pipe lines and pressure elements of hydraulic transmission system and control system for controllable pitch propellers are to be subject to hydraulic tests to a pressure of 1.5 times the design pressure. On completion of installation, the system is to be tested to 1.25 times the working pressure for tightness, but need not exceed the design pressure plus 7 MPa.

11.3.6.14 Controllable pitch propeller and its main parts are to be subject to material test and non-destructive test according to the relevant requirements of ISC Rules for Materials and Welding.

11.3.6.15 A sealing is to be inserted between the propeller blade and the propeller boss to prevent the ingress of sea water and sand as well as the leakage of lubricating grease.

11.3.6.16 The inside of the propeller bosses is to be filled up with lubricating grease.

11.3.7 *Z propulsion arrangement*

11.3.7.1 Z propulsion arrangement is to be provided with means to control its propulsion direction from bridge, machinery control station (if any) and on the spot. Indicators of direction of thrust are to be provided in these control locations.

11.3.7.2 When the output shaft of main engine and input shaft of Z propulsion arrangement are not in the same level, universal couplings are to be provided in pair with same angle which is in general not to be more than 10°.

11.3.7.3 If Z propulsion arrangement has electric or electro-hydraulic power equipment of steering turning device , spare power equipment or other emergency control measures are to be provided.

If there are two or more Z propulsion arrangement on the ship, spare power equipment is not necessary.

11.3.7.4 The diameters of input shaft, vertical shaft and propeller shaft of Z propulsion arrangement are not to be less than the value obtained from calculation according to the formula in 11.2.2.1 of this Chapter.

11.3.7.5 Shafting vibration calculation of Z propulsion arrangement is to comply with the requirements in Chapter 12 of this PART.

11.3.7.6 Strength and installation of propeller of Z propulsion arrangement are to comply with the requirements in Section 4, Chapter 11 of this PART.

11.3.7.7 All alarms related to system failure are to be shown on maneuvering console. Z propulsion arrangement is to have alarm function under following conditions:
(1) low pressure of lubricating oil;
(2) high temperature of lubricating oil;
(3) low level of hydraulic oil;
(4) low pressure of hydraulic oil;
(5) high temperature of hydraulic oil (if fitted with oil cooler);
(6) too high pressure difference of hydraulic oil filter (if fitted with oil filter);
(7) low pressure of clutch.
11.3.7.8 On completion of manufacture of parts of Z propulsion arrangement such as upper and lower gearbox, rotating rudder gearbox and rudder post, 0.2 MPa hydraulic test is to be carried out and tightness test is to be carried out after assembly. Tightness test may be carried out using liquid with 0.1 MPa pressure, and 0.03 MPa compressed air may be used for test examination by means of applying soap liquid. No leakage is permitted.
11.3.7.9 Hydraulic pipes are to be subject to hydraulic tests to a pressure of 1.5 times the design pressure. On completion of installation, they are to be tested together with fittings to 1.25 times the design pressure for tightness.
11.3.7.10 Z propulsion arrangement together with its main parts and accessories are to be subject to material test and non-destructive test according to ISC Rules for Materials and Welding.
11.3.7.11 Steering gear of Z propulsion arrangement is to comply with the requirements of Section 1, Chapter 13 of this PART.

11.3.8 *Transverse propulsion arrangement*

11.3.8.1 Transverse propulsion arrangement is to have sufficient transverse thrust to satisfy the working requirements of navigation at low speed and docking and leaving wharf.
11.3.8.2 Material and test of transverse propulsion arrangement and its components are to comply with the relevant requirements of ISC Rules for Materials and Welding.
11.3.8.3 Diesel engines driving transverse propulsion arrangement are to comply with the relevant requirements in Chapter 9 of this PART.
11.3.8.4 Motor and distribution system of driving transverse propulsion arrangement are to comply with the relevant requirements in PART FOUR of the Rules.
11.3.8.5 The design of shafting together with its parts and propeller is to comply with the relevant requirements of this Chapter.
11.3.8.6 The thickness of tunnel of transverse propulsion arrangement is not to be less than the adjacent part of the hull.
11.3.8.7 The shaft sealing box is to be installed to prevent water so as to protect steel shafts from sea water.
11.3.8.8 Alarm is to be in the bridge with individual or groupwise indicator for the following faults:
(1) overload of prime mover and servo unit;
(2) power failure of remote control system;
(3) power failure of alarm system;
(4) low level in lubrication oil tank (if fitted);
(5) low lubrication oil pressure (if forced lubrication oil system);
(6) low level in hydraulic supply tank;
(7) low pressure in hydraulic system.
11.3.8.9 Individual indication in the bridge is required for:
(1) running and stop of prime mover;
(2) propeller pitch for controllable pitch propeller plants;
(3) direction of rotation and r.p.m. for fixed propeller plants.
11.3.8.10 It is to be possible to stop the transverse propulsion arrangement from the bridge by means of a system independent of the remote control system.
11.3.8.11 Instrumentation and automation are also to comply with the relevant requirements of PART SEVEN of the Rules.

Section 4 PROPELLERS

11.4.1 *General requirements*

11.4.1.1 Propellers are to be subject to surface inspection and size verification as well as to static

balancing test. For built-up propellers and controllable pitch propellers, the static balancing test is to be carried out respectively after machining and assembling.

11.4.1.2 Blade fastening studs of built-up propellers are to be made of forged steel having a tensile strength not less than 400 N/mm^2.

11.4.1.3 Fasteners (studs, nuts, etc.) for propellers and for their accessories are to be fitted with reliable devices to prevent loosening and corrosion.

11.4.2 *Clearances between propeller and hull*

11.4.2.1 For the purpose of modifying the effect of propeller excitation on hull, the necessary minimum clearances between the propeller and the hull are to be provided as specified in 2.14.4 of PART TWO of the Rules.

11.4.3 *Thickness of propeller blades*

11.4.3.1 The thickness of propeller blades t (at 0.25 *R* and 0.6 *R* for solid propellers, and at 0.35 *R* and 0.6 *R* for controllable pitch propellers) is not to be less than that calculated by the following formula:

$$t = \sqrt{\frac{Y}{K - X}} \qquad \text{mm}$$

where: Y — power coefficient, to be obtained from 11.4.3.2 of this Section;

K — material coefficient given in Table 11.4.3.1;

X — speed coefficient, to be obtained from 11.4.3.3 of this Section.

Propeller material coefficient K *Table 11.4.3.1*

Material	tensile strength R_m (N/mm^2)	Material density G (g/cm^3)	Material coefficient K
Carbon steel and alloy steel	400	7.9	0.57
Ferritic and martensitic stainless steel	500	7.7	1.04
Austenitic stainless steel	450	7.9	1.04
Cu1 manganese bronze	440	8.3	1
Cu2 nickel-manganese bronze	440	8.3	1
Cu3 nickel-aluminum bronze	590	7.6	1.38
Cu4 manganese-aluminum bronze	630	7.5	1.17

Note: For materials other than specified in the above Table, the value K may be determined by making reference to those given in the Table.

11.4.3.2 Power coefficient Y is to be calculated by the following formula:

$$Y = \frac{1.36 A_1 N_e}{Z b n_e}$$

where: $A_1 = \frac{D}{P}(K_1 - K_2 \frac{D}{P_{0.7}}) + K_3 \frac{D}{P_{0.7}} - K_4$;

D — propeller diameter, in m;

P — pitch at the section under consideration, in m;

$P_{0.7}$— pitch at 0.7 R, in m;

R — propeller radius, in m;

K_1, K_2, K_3, K_4— coefficients given in Table 11.4.3.2;

N_e— rated power of the main engine, in kW;

Z — number of blades;

b — blade width at the section under consideration, in m;

n_e— speed of the propeller at rated power of main engine, in r/min.

For aerofoil sections with trailing edge washback, the value of A_1 obtained from above formula is to be increased by 30%. The trailing edge washback is the offset of the trailing edge of the tangent plane of the propeller blade in respect to the pitch baseline (external chord) of the blade face, as shown in Figure 11.4.3.2, e.g. 0.6R without washback and 0.25R with washback.

Coefficient K values in way of different diameters of propeller *Table 11.4.3.2*

K / r	K_1	K_2	K_3	K_4	K_5	K_6	K_7	K_8
0.25R	634	250	1410	4	82	34	41	380
0.35R	520	285	1320	16	64	28	57	420
0.60R	207	151	635	34	23	12	65	330

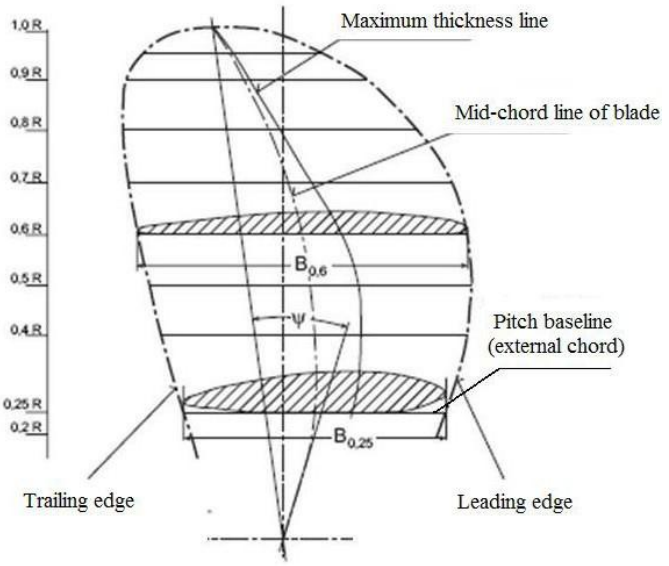

Figure 11.4.3.2

11.4.3.3 Speed coefficient X is to be calculated by the following formula:

$$X = \frac{A_2 G A_d n_e^2 D^3}{10^{10} Zb}$$

where: $A_2 = \frac{D}{P}(K_5 + K_6\varepsilon) + K_7\varepsilon + K_8$

D, P, n_e, Z and b as defined in 11.4.3.2 of this Section;

ε — rake angle of propeller blade, in degrees. The value of the rake angle is positive for backward rake and negative for forward rake. The rake angle is, as shown in the side view of propeller, is an angle taken in one of the following three conditions:

— ε_1 and ε_2 are backward rake angles: the more backward one is to be taken ($\varepsilon = \varepsilon_1$, as shown in Figure 11.4.3.3.3(1));

— ε_1 and ε_2 are forward rake angles: the less forward one is to be taken ($\varepsilon = \varepsilon_2$, as shown in Figure 11.4.3.3.3(2));

— ε_1 and ε_2 are rake angles on both sides of the centreline: the backward one is to be taken ($\varepsilon = \varepsilon_1$, as shown in Figure 11.4.3.3.3(3)).

ε_1 is the angle measured from the line perpendicular to shaft centerline to the tangent to the backward thickness line at the radius 0.6R of the side projection of propeller blade;

ε_2 is the angle obtained by the following formula:

$$\varepsilon_2 = \tan^{-1}\frac{e}{R}$$

where: e — rake (radial inclination of blade section forward or backward from the reference line, taken as the distance between the blade tip projected on the propeller shaft and the intersection of the reference line and the propeller axis), in m;

R — the same as in 11.4.3.2.

K_5, K_6, K_7, K_8 — coefficients given in Table 11.4.3.2;

G — density of the propeller material, in g/cm^3;

A_d — expanded area ratio.

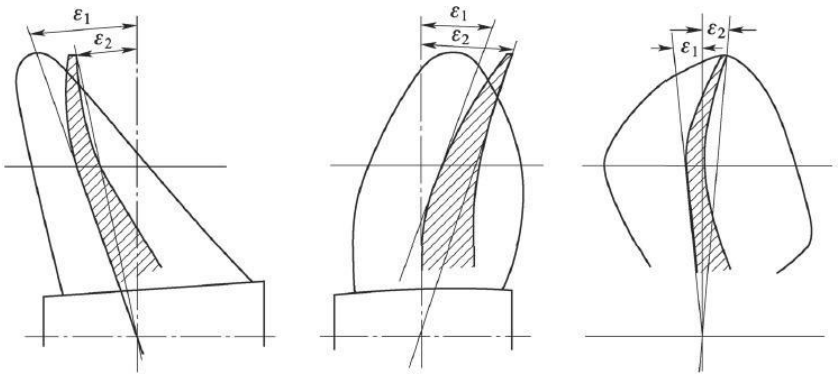

Figure 11.4.3.3 Rake Angle of Propeller Blade

11.4.3.4 The thickness of propeller blades is permitted to be calculated by some other appropriate methods, but background of test results or service experience is to be provided.

11.4.3.5 Depending on the condition of application of the propeller, detailed data of wake field in periphery of the propeller or blade thickness increase may be required.

11.4.4 *Fitting of propellers to screwshafts*

11.4.4.1 Where it is proposed to fit the propeller to the screwshaft with a flange, the diameter of flange bolts is to comply with the requirements of 11.3.3.1 and 11.3.3.3 of this Chapter, and the thickness of flanges is to comply with the provisions of 11.3.2.1(2) of this Chapter.

11.4.4.2 Where it is proposed to fit the propeller to the screwshaft with a key, the propeller boss is to be a good fit on the screwshaft cone. The length of the forward fitting surface is to be about the diameter of the screwshaft.

The taper of the coned end of screwshaft is not to exceed 1/10, and for keyless propellers fitted by oil injection method, such taper is not to exceed 1/15.

The intersection of cylindrical and conical portions of screwshafts is not to be shouldered or rounded. The forward end of the keyway in the screwshaft is to be smoothed and sled-runner shaped. In general, the shape and size may be in accordance with Figure 11.4.4.2, where $r_1 < r_2 < r_3 < r_4$, $AB = BC = CD = DF = x$ (x being depth of keyway). For r_1, r_2, r_3 and r_4, refer to the following:

$r_1 = x/8$, $r_2 = 3x/8$, $r_3 = 3x/4$, $r_4 = x$.

The values of r_5 are given in Table 11.4.4.2.

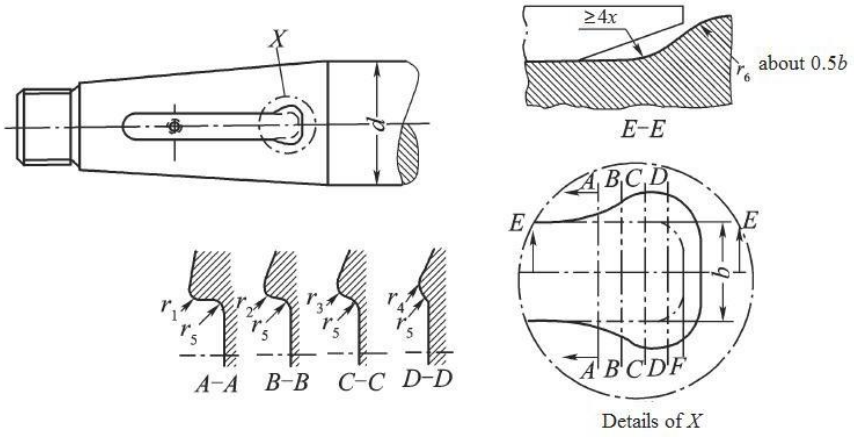

Figure 11.4.4.2

Values of r_5 **Table 11.4.4.2**

d (mm)	r_5 (mm)	d (mm)	r_5 (mm)
$d \leq 150$	3	$250 < d \leq 400$	5
$150 < d \leq 250$	4	> 400	6

The distance from the forward end of the keyway to the big end of conical portion of the shaft is not to be less than 0.2 times the diameter of the big end.

There is to be a clearance between the top of the key and the boss. The lateral sides of the key are to be in close contact with those of the keyways in the screwshaft and the propeller boss. The bottom of the keyways are to be provided with a smooth fillet, and the fillet radius is not to be less than 1.25% of the diameter of the big end of the cone.

Keys are to be secured to the shafts by screws. The forward screw is to be placed at least 1/3 of the length of the key from the end. The depth of the screw holes is not to exceed the diameter of screw holes, and the edges of the holes are to be beveled.

The outside diameter of the threaded end for the propeller retaining nut is not to be less than 60% of the calculated diameter of the propeller shaft.

11.4.4.3 Where the torques are transmitted completely by the keys, the effective sectional area of the key in shear is not to be less than the value determined by the following formula, and the tensile strength of the material is to be equal to or greater than that of the shaft material:

$$BL \geq \frac{d^3}{2.35 d_m} \qquad \text{mm}^2$$

where: B — breadth of the key, in mm;

L — effective length of the key, in mm;

d — diameter required for the intermediate shaft, in mm, to be taken as 800 N/mm^2 when the tensile strength of intermediate shaft material is greater than 800 N/mm^2 during calculation;

d_m — diameter of shaft at mid-length of the key, in mm.

11.4.4.4 The fitting of a keyed propeller is preferable to meet the following requirements, and the size of keys may be suitably reduced:

(1) the safety factor of friction force against sliding is not to be less than 1.0 at sea water temperature of 35°C;

(2) the inner surface pressure of propeller boss is not to be less than 20 MPa at sea water temperature of 15°C;

(3) the equivalent uniaxial stress at the inner surface of propeller boss is not to be more than 35% of the specified minimum yield stress of the material concerned at sea water temperature of 0°C.

11.4.5 *Fitting of keyless propeller by oil shrink method*

11.4.5.1 Where keyless fitting propellers with oil pressure, the axial pull-up length from propeller boss to shaft is to be in compliance with the requirements of 11.4.5.2.

11.4.5.2 The maximum equivalent uniaxial stress in the boss at 0°C based on the Mises-Hencky criterion is not to exceed 70% of the yield point or 0.2% proof-stress (0.2% offset yield strength) for the propeller material based on the test piece value. For cast iron, the value is not to exceed 30% of the nominal tensile strength.

Where keyless fitting propellers with oil pressure, the axial pull-up length S from propeller boss to shaft may also meet the formulae given below:

Minimum required surface pressure at 35°C:

$$P_{35} = \frac{S_F T}{AB}\left(-\frac{S_F K}{2} + \sqrt{\mu^2 + B\left(\frac{F_v}{T}\right)^2}\right) \qquad \text{N/mm}^2$$

Minimum pull-up length at 35℃:

$$S_{35} = P_{35}\frac{d_1}{K}\left(\frac{1}{E_2}\left(\frac{K_2^{\,2}+1}{K_2^{\,2}-1} + \mu_2\right) + \frac{1}{E_1}(1-\mu_1)\right) \qquad \text{mm}$$

Minimum pull-up length at temperature t ($t < 35$℃):

$$S_t = S_{35} + \frac{d_1}{K}(a_2 - a_1)(35 - t) \qquad \text{mm}$$

Corresponding minimum surface pressure at temperature t:

$$P_t = P_{35}\frac{S_t}{S_{35}} \qquad \text{N/mm}^2$$

Minimum push-up load at temperature t:

$$W_t = AP_t\left(\mu + \frac{K}{2}\right) \qquad \text{N}$$

Maximum permissible surface pressure at 0℃:

$$P_{max} = \frac{0.7R_{eH}(K_2^2-1)}{\sqrt{3K_2^4+1}} \quad \text{N/mm}^2$$

Maximum pull-up length at 0℃:

$$S_{max} = \frac{P_{max}}{P_{35}} S_{35} \quad \text{mm}$$

Maximum pull-up length at 35℃:

$$S_{max} = \frac{P_{max}}{P_{35}} S_{35} - \frac{35(\alpha_2-\alpha_1)d_1}{K} \quad \text{mm}$$

where: $B = \mu^2 - \frac{S_F^2 K^2}{4}$

$$F_v = \frac{2000CM_e}{d_1} \quad \text{N}$$

$$T = 1762\frac{N_e}{V} \quad \text{N}$$

S_F — factor of safety against friction slip at 35°C, not to be less than 2.8 under the action of rated torque (based on rated power r.p.m.) plus torque due to torsionals;

T — rated thrust, in N;

V — ship speed at rated horsepower, in kn;

μ — coefficient of friction between mating surfaces. For the oil injection method, the coefficient of friction is to be 0.13 for bosses made in copper-based alloy and steel;

F_v — shear force at interface, in N;

M_e — rated torque corresponding to N_e and n_e, in Nm;

C — constant:

C = 1 for turbines, geared diesel drives, electric drives and for direct diesel drives with a hydraulic or an electromagnetic or high elasticity coupling;

C = 1.2 for a direct diesel drive.

The c constant is increased if the shrinkage has to absorb an extreme high pulsating torque.

Maximum pull-up length at 35°C:

$$S_{max} = \frac{P_{max}}{P_{35}} S_{35} - 35(\alpha_2-\alpha_1)d_1/K \quad \text{mm}$$

where: K — taper of the propeller shaft cone, $K \leq 1/15$;

N_e — rated output transmitted to the propeller shaft, in kW;

n_e —propeller speed at rated output Ne, in r/min;

A —100% theoretical contact area of propeller boss and propeller shaft, in mm^2, as read from drawings and disregarding oil grooves;

$K_2 = \frac{d_2}{d_1}$

d_1 —diameter of propeller shaft at the midpoint of the taper in the axial direction, in mm;

d_2 — mean outer diameter of the propeller boss at the axial position corresponding to d_1, in mm;

μ_1 — Poisson's ratio for shaft material, see Table 11.4.5.2;

μ_2 — Poisson's ratio for propeller material l, see Table 11.4.5.2;

E_1 — modulus of elasticity of propeller shaft material, see Table 11.4.5.2;

E_2 — modulus of elasticity of propeller material, see Table 11.4.5.2;

t — temperature at time of fitting propeller on shaft, in°C;

α_1 — coefficient of linear expansion of propeller shaft material, see Table 11.4.5.2;

α_2 — coefficient of linear expansion of propeller material, see Table 11.4.5.2;

R_{eH} — yield point or 0.2% proof stress of propeller material, in N/mm^2.

Material factor Table 11.4.5.2

Material	Modulus of elasticity	Poisson's ratio	coefficient of linear expansion (1/℃)
Cast and forged steel	20.6×10^4	0.29	12×10^{-6}

Material	Modulus of elasticity	Poisson's ratio	coefficient of linear expansion (1/℃)
Cast iron	9.8×10^4	0.26	12×10^{-6}
Copper-based alloy Cu1 and Cu2	10.8×10^4	0.33	17.5×10^{-6}
Copper-based alloy Cu3 and Cu4	11.8×10^4	0.33	17.5×10^{-6}

11.4.5.3 Where keyless propellers are fitted by the oil shrink method at a temperature below 0℃, the ambient temperature for fitting the propeller to the shaft is not to be less than the value calculated by the following formula:

$$t_{\min} = \frac{KP_{\max}S_{35} - P_{35}KS_{35} - 35P_{35}d_1(\alpha_2 - \alpha_1)}{P_{35}d_1(\alpha_1 - \alpha_2)} \quad ℃$$

11.4.5.4 Prior to final pull-up, the contact area between the mating surfaces is to be checked and is not to be less than 70% of the theoretical contact area (100%). Non-contact bands extending circumferentially around the boss or over the full length of the boss are not acceptable. After final pull-up, the propeller is to be secured by a nut on the propeller shaft. The nut is to be secured to the shaft.

11.4.5.5 Prior to final pull-up, the propeller and shaft are to be at the same temperature and the mating surfaces are to be clean and free from oil or grease. The bedding of the propeller with the shaft is to be demonstrated in the workshop to the satisfaction of the Surveyor.

11.4.5.6 A copy of the fitting curve relative to temperature, and data of corresponding loads are to be kept on board. Special tools for fitting and dismantling purposes are also to be provided on board.

11.4.5.7 The formulae given in 11.4.5.2, for the ahead condition, will also give sufficient safety in the astern condition. The formulae are applicable for solid shafts only and are not applicable for propellers where a sleeve is introduced between shaft and boss.

CHAPTER 12 SHAFT VIBRATION AND ALIGNMENT

Section 1 GENERAL PROVISIONS

12.1.1 *General requirements*

12.1.1.1 The arrangement of shafting and the scantlings of shafts are, in addition to the provisions of Chapter 11 of this PART, to comply with the requirements of this Chapter. The whole shafting could only be finally approved after the previous approval of the torsional, axial and lateral vibrations as well as the alignment of the said shafting.

12.1.1.2 Calculations for vibration and alignment of shafting are to be submitted for approval. Reports on measurements as deemed necessary are to be submitted for approval or information.

12.1.1.3 Novel and sophisticated shafting may be approved provided that measurement reports for similar installations are available and proved to be in compliance with the provisions of this Chapter.

12.1.1.4 Where changes are subsequently made to a shafting which has been approved, e.g. by fitting a highly flexible coupling, changing the size of shaft bearings and the engine type, or fitting a gearbox or a propeller of a different design, or changing the number of bearings etc. revised calculations of shaft vibration and alignment are to be made as appropriate and submitted for approval.

12.1.1.5 Calculations of shaft vibration and alignment are to include the detailed specifications and documents necessary for approval and checking.

12.1.1.6 In addition to shafting alignment requirements in Section 5 of this Chapter, ships complying with the provisions of Appendix 1 of this Chapter may be assigned the notation ESA upon request.

12.1.2 *Restricted speed ranges*

12.1.2.1 Restricted speed ranges will be imposed in the regions of resonant speeds n_c, where amplitudes or stresses or torques resulting from shaft vibration exceed the limiting values for continuous running as specified in this Chapter. The engine is not to be run continuously in such restricted speed ranges.

12.1.2.2 The following speed range is to be avoided:

$$\frac{16n_c}{18-r} \sim \frac{(18-r)n_c}{16}$$

where: $r = n_c / n_e$, n_e being the rated speed (r/min).

12.1.2.3 The restricted speed range for continuous operation may be suitably extended where amplitudes or stresses or torques resulting from vibration approach the limiting values for transient running as specified in this Chapter, and may be adequately reduced where they marginally exceed the limiting value for continuous running.

12.1.2.4 Restricted speed ranges may also be ascertained by measurements, i.e. the range of speed to be avoided for continuous running may be taken as that over which the measured values of amplitudes, or stresses, or torques resulting from shaft vibration are in excess of those allowed for continuous running, having regard to the tachometer accuracy.

12.1.2.5 Where the torsional vibration causes hammering of transmission gears or where the pulsatory torque of the elastic elements exceeds the allowable value for continuous running, restricted speed ranges are also to be imposed.

12.1.2.6 Where restricted speed ranges are imposed, the tachometer accuracy is to be within ±2% in way of the restricted speed range.

12.1.2.7 Restricted speed ranges are to be marked red on the tachometer, and notice boards are to be fitted in front of the control stations.

12.1.3 *Measurements*

12.1.3.1 Manufacturers are required to carry out torsional and axial (if required) vibration measurements on benches to their products of a new design or having undergone a major alteration, and to have all the equivalent parameters checked.

12.1.3.2 ISC may decide whether measurements are required for verification, depending upon the conditions of the method of calculation, the magnitudes of amplitudes or stresses or torques contained in the calculations submitted. The vibration measurements may be dispensed with provided that measurement reports for similar installations are submitted and proved to be in compliance with the provisions of this Chapter.

12.1.3.3 The instrumentation, measured points and a series of revolution step of vibration measurements

are to be such that they can correctly demonstrate the characteristics of vibration mode to be measured.

Alternating torsional stresses are amplitudes of the maximum and minimum torsional stresses, which can be measured in relevant conditions of repetitive cycle process.

12.1.3.4 Where the difference between the measured and calculated values of natural vibration frequency is less than ±5%, the amplitudes or stresses (torque) at any cross-section of the system may be generally estimated by the measured amplitudes or stresses (torque) in accordance with the vibration mode under consideration.

12.1.3.5 The measurement reports of torsional vibration are to include order, angular amplitude or stress, natural frequency, torsional vibration of each shaft, vibratory torque of the gear and elastic couplings (where applicable) at each measuring point under test speed, and to make stress/torque and speed curves with the allowable value.

12.1.3.6 During measurement, the main engine is to start from the minimum steady speed to the rated speed, and the measurement is to be carried out under the condition of different speed and steady speed. Near the resonance speed, the speed separation is to be reduced appropriately.

12.1.3.7 In general, torsional vibration is to be measured in the following cases:

(1) the calculated torsional vibration stress has reached 70% of that permitted for continuous operation or over within the speed range of $r = 0.8$ to 1.0;

(2) the calculated torsional vibration stress is less than, but has reached 90% of that permitted for transient operation within the speed range of $r < 0.8$;

(3) certain novel shafting systems contain unconventional parts.

12.1.4 *Miscellaneous*

12.1.4.1 Where the bed-plates of machinery are installed on resilient mountings, the shafting is to be elastically connected.

12.1.4.2 The method of calculation and the particulars to be submitted in relation to the requirements of this Chapter may refer to ISC Guidelines for Vibration Control on Board Ships.

12.1.4.3 The pressure gauge and lower pressure alarm or amplitude monitoring device for oil supply are to be fitted for torsional or axial vibration dampers, for which the oil is supplied from the lubricating oil circulating system for main engine, unless effective measures are to be taken to identify the normal work of the vibration dampers.

12.1.4.4 The allowable stress of torsional vibration and allowable amplitude values of axial vibration may also be ascertained in accordance with Appendix 3, Chapter 9 of this PART.

Section 2 TORSIONAL VIBRATION

12.2.1 *Application*

12.2.1.1 The requirements of this Section are applicable to the following systems:

(1) main diesel engine propulsion systems, except in the case of ships classed for port service when fitted with engines having powers less than 110 kW.

(2) auxiliary diesel engine systems used for essential services, where the power developed by the auxiliary engines is 110 kW or over.

(3) propulsion systems formed by turbines;

(4) propulsion systems formed by electric motors.

12.2.2 *Torsional vibration calculations*

12.2.2.1 Torsional vibration calculation is to include: engine type, rated power, rated speed, shafting arrangement, tensile strength of shaft, equivalent parameters of torsional vibration for the dynamic system with necessary specification, Holzer tables for each vibration node under consideration and the associated vectorial sums of relative amplitudes, vibratory response calculation of main harmonics and the corresponding permissible values.

12.2.2.2 Where installations have different application conditions, e.g. combined with clutches, P.T.O. systems or having more than one engine, the torsional vibration calculations are to be carried out for each case.

12.2.2.3 Where there is considerable difference between the sizes of the spare propeller and the working propeller, torsional vibration is also to be calculated for the condition when the spare propeller is used.

12.2.2.4 The special speed requirements for prolonged periods in service are also to be indicated, e.g. the range of the service speed of a controllable pitch propeller and the range of the service speed of a P.T.O. system, etc.

12.2.2.5 Where controllable pitch propellers are fitted, torsional vibration calculations for zero and full

pitches are to be carried out.

12.2.2.6 Torsional vibration calculation is to be carried out with one cylinder misfiring in addition to that under normal working condition.

12.2.2.7 In general, the calculation is to cover the resonant conditions arising from all harmonic torque excitation up to order 12, in a speed range of 0.8 n_{min} to 1.2 n_e (n_{min} being the minimum steady speed, in r/min). For diesel engine propulsion system, if energy method is adopted to calculate torsional vibration, the calculation of non-resonant condition over 1.2 n_e, resulting from the main harmonic of one node vibration, is also to be carried out.

12.2.3 *Allowable stresses*

12.2.3.1 The allowable torsional vibration stresses for shafting are to be calculated based on the basic diameters of the shafts, i.e. the crankpin diameter for crankshafts, the minimum diameter for intermediate shafts and the minimum diameter between the aft bearing and the bulkhead gland for screwshafts, and the effect of the stress concentration on the plain sections of the shafting may be neglected.

12.2.3.2 The allowable torsional vibration stresses for main engine crankshafts are not to exceed the values given by the following formulae:

Continuous running ($0 < r \leq 1.0$):

$$[\tau_c] = \pm [(52-0.031d)-(33.8-0.02d)\, r^2] \quad N/mm^2$$

($1.0 < r \leq 1.05$):

$$[\tau_c] = \pm [(18.1-0.0113d)+(87.3-0.052d)\sqrt{r-1}\,] \quad N/mm^2$$

Transient running ($0 < r < 0.8$):

$$[\tau_t] = \pm 2.0\, [\tau_c] \quad N/mm^2$$

The symbols used in 12.2.3.2 to 12.2.3.4 are defined as follows:

$[\tau_c]$ — allowable torsional vibration stress for continuous running, in N/mm^2; $[\tau_t]$ — allowable torsional vibration stress for transient running, in N/mm^2;

d — basic diameter of shafts, in mm;

$r = n_c/n_e$;

n_c — critical speed, in r/min;

n_e — rated speed, in r/min.

12.2.3.3 High cycle fatigue criterion (typically >> 10^7), i.e. torsional vibration stresses permitted for continuous operation as well as reverse bending stresses. The influence of reverse bending stresses is addressed by the safety margins, see the provisions of 11.2.2, Chapter 11 of this PART.

The allowable torsional vibration stresses for thrust, intermediate, tube shafts and screwshaft are not to exceed the values given by the following formulae:

Continuous running ($0 < r < 0.9$):

$$[\tau_c] = \pm C_W C_K C_D (3-2\, r^2) \quad N/mm^2;$$

($0.9 \leq r \leq 1.05$):

$$[\tau_c] = \pm 1.38\, C_W C_K C_D \quad N/mm^2;$$

Transient running ($0 < r \leq 0.8$):

$$[\tau_t] = 1.7\, [\tau_c] / \sqrt{C_K} \quad N/mm^2$$

where: C_W — material factor; $C_W = (R_m + 160)/18$;

R_m — specified tensile strength of shaft material, in N/mm^2. For intermediate shaft, when carbon and manganese steel is used, it is to be taken as 600 N/mm^2 for R_m> 600 N/mm^2; when alloy steel is used, it is to be taken as 800 N/mm^2 for R_m> 800 N/mm^2. For special approval of alloy steel used for intermediate shaft material, the tensile strength of shaft material may be greater than 800 N/mm^2, but less than 950 N/mm^2, where such approval of the material comply with the relevant requirements for torsional fatigue test①, cleanliness ② and inspection. The requirements of 5.1.1.1, 5.3.2.1, 5.3.2.3 and 5.3.4.5 for the cleanliness of material, and the requirements of 5.1.6 for the inspection in Chapter 5, PART ONE of ISC Rules for Materials and Welding are to be complied with. For screwshaft and tube shaft, it is to be taken as 600 N/mm^2 for R_m> 600 N/mm^2;

C_K — shape coefficient, see Table 12.2.3.3;

C_D — size factor: $C_D = 0.35+0.93\, d^{-0.2}$. The size factor being a function of diameter only does not

① Torsional fatigue test is to meet the requirements of 7.4.6 of Guidelines for Inspection of Forged Steel.

② Cleanliness is to meet the requirements of 7.4.6 of Guidelines for Inspection of Forged Steel.

purely represent a statistical size influence, but rather a combination of this statistical influence and the notch sensitivity.

Shape coefficient C_K *Table 12.2.3.3*

Intermediate shafts						Thrust shafts		Propeller shafts and tube shafts		
Integral coupling flange	Shrink fit coupling	Keyway, tapered connection	Keyway, cylindrical connection	Radial hole	Longitudinal slot	On both sides of thrust collar	In way of axial bearings where roller bearing is used as thrust bearing	Flange mounted or keyless taper fitted propeller shafts	Key fitted propeller shafts	The portion of the screwshaft and tube shaft forward of the length of screwshaft required by 11.2.2.3 till it reaches the aft peak bulkhead
1.0①	1.0①	0.6	0.45	0.50	0.30②	0.85	0.85	0.55	0.55	0.8

Notes: ① For multiple-arc transition intermediate shaft, if C_K is greater than 1, the testing basis or service experience is to be provided and approved by ISC.

② C_K = 0.3 is a safe approximation within the limitations in note 4 of Table 11.2.2.1. More accurate estimate of the shape coefficient C_K may be determined by direct application of FE calculation or the following formula. In which case:

$$C_K = \frac{1.45}{scf}$$

where: *scf* — stress concentration factor, which is defined as the ratio between the maximum local principal stress and $\sqrt{3}$ times the nominal torsional stress (determined for the bored shaft without slots), to be calculated according to following formula:

$$scf = 2.3 + 0.8 \times \frac{(l-e)/d}{\sqrt{(1-d_0/d)\times e/d}}$$

l — length of slot, in mm;
e — width of slot, in mm;
d — basic diameter of shaft, in mm;
d_0 — actual bore of shaft, in mm.
This formula applies to:
- slots at 120 or 180 or 360 degrees apart.
- slots with semicircular ends. A multi-radii slot end can reduce the local stresses, but this is not included in this empirical formula.
- slots with no edge rounding (except chamfering), as any edge rounding increases the scf slightly.

$$\alpha_{t(hole)} = 2.3 - 3\times\frac{e}{d} + 15\times\left(\frac{e}{d}\right)^2 + 10\times\left(\frac{e}{d}\right)^2\times\left(\frac{d_i}{d}\right)^2$$

$\alpha_{t(hole)}$ represents the stress concentration of radial holes or simplified to 2.3.

12.2.3.4 The allowable torsional vibration stresses for the crankshafts and transmission shafts of diesel engines for generators and of auxiliary diesel engines for essential services and for the crankshafts of propulsion diesel engines running with constant speed are not to exceed the values given by the following formulae:

Continuous running $(0.9 \le r \le 1.10)$:

$$[\tau_c] = \pm (21.59 - 0.0132d) \quad N/mm^2;$$

Transient running $(0 < r < 0.95)$:

$$[\tau_t] = \pm 5.5\,[\tau_c] \quad N/mm^2.$$

12.2.3.5 For propulsion shafting running at constant speed, higher vibratory stress limits may be considered if background of service experience is provided.

12.2.3.6 Except the shafting material is of nodular graphite cast iron, the tensile strength of intermediate shaft material specified in 12.2.3.2 and 12.2.3.4 is greater than 430N/mm^2, the allowable stress τ' may be calculated by the following formula:

$$\tau' = \frac{R_m + 184}{614}\tau \quad N/mm^2$$

where: R_m — tensile strength of shaft material, in N/mm^2, to be taken as 600 N/mm^2 for R_m > 600 N/mm^2;

τ — allowable torsional vibration stress determined by 12.2.3.2 and 12.2.3.4 of this Section, in N/mm^2.

12.2.4 *Additional requirements for generators*

12.2.4.1 In the case of alternating current generators, the resultant vibration amplitudes at the rotor are not

to exceed 3.5 ° electrical degrees under rated load working conditions. Where the inverter provided with rectification can ensure the output of stable power supply to the grid for normal use, the electrical degree is not limited to 3.5° .

12.2.4.2 The vibratory inertia torques imposed on the generator rotors are to be limited to ± 2 M_e over the speed range of r = 0.95 to 1.10 (M_e being the torque at the rated speed), and to ± 6 M_e over the range of r < 0.95. Where a main engine drives two or more generators, the rated torque of each generator is to be taken into consideration separately.

12.2.5 *Allowable vibratory torques for gearing and flexible coupling*

12.2.5.1 The vibratory torque at gear engagement of the transmission gearing arrangements is not, in general, to exceed 1/3 of the rated full load mean torque in the range of r = 0.9 to 1.05. In cases where tooth surface contact stress and root bending stress of gears are less than the allowable values specified in Appendix 1, Chapter 10 of this PART, special consideration will be given to the acceptance of higher vibratory torque on the gears, but gear knock does not happen.

12.2.5.2 Flexible couplings are to be of such design that vibratory torque of the elastic elements is not to exceed the allowable pulsatory torque for continuous running and not to exceed the allowable pulsatory torque for transient running in the respective running conditions.

12.2.5.3 On the power output branch without load, the vibratory torque at gear engagement is not, in general, to exceed 20% of the rated full load mean torque.

12.2.6 *Miscellaneous*

12.2.6.1 No critical speed is to occur in the range of speed for normal service or in any special speed ranges required for service.

12.2.6.2 Restricted speed ranges in normal operating conditions (r = 0.8 to 1.0) are not acceptable. Restricted speed ranges in one-cylinder misfiring conditions of single propulsion engine ships are to enable safe navigation.

12.2.6.3 The torsional vibration stresses caused by the upper flank at r = 0.8 are not to exceed the allowable stress [τ_c].

12.2.6.4 Resulted stresses arising from resonance and major non-resonance are not to exceed 1.5 times the allowable torsional vibration stresses limited by this Section in the range of r = 0.8 to 1.05.

12.2.6.5 Where data from experience or detailed calculations are furnished by manufacturers, allowable torsional vibration stresses (or torques) as supplied by the manufacturers may be adopted.

12.2.6.6 The allowable torsional vibration stresses for crankshafts may also be obtained in accordance with the Unified Requirements of IACS. However the calculations are to be submitted in accordance with the requirements of Appraisal of Crankshaft Strength of Diesel Engines in Appendix 3, Chapter 9 of this PART.

Section 3 AXIAL VIBRATION

12.3.1 *General requirements*

12.3.1.1 For all main propulsion shafting systems, the ship-builders and designers are to ensure, so far as practicable, that excessive axial vibration amplitudes throughout the speed range are not to occur. Otherwise, restricted speed ranges are to be imposed or suitable means for reducing the amplitudes are to be provided as appropriate.

12.3.1.2 Documents of axial vibration characteristics of the slow-speed two-stroke diesel engine direct propulsion shafting systems and of the turbine propulsion shafting systems are to be submitted for approval.

12.3.2 *Axial vibration calculations*

12.3.2.1 Axial vibration calculations are to include: engine type, rated power, rated speed, shafting arrangement, equivalent parameters of systems and the necessary specification, the Holzer tables of 0-node and 1-node vibration and the associated vectorial sums of relative amplitudes difference, the vibratory response of major harmonics and the associated limits.

12.3.3 *Allowable amplitudes*

12.3.3.1 For diesel engine propulsion shafting systems, axial vibration amplitudes for continuous running arising from axial vibration in the range of r=0 to 1.0 are not to exceed the values calculated by following formula:

$$[A_{a1}] = \frac{R[\Delta a_0]}{2(\Delta a_k)_{max}(R + \frac{d_j}{2})} \quad \text{mm}$$

where: $[A_{a1}]$ — allowable axial vibration amplitude for continuous running at the free-end of the crankshaft, in mm;

$(\Delta_{ak})_{max}$ — the maximum relative amplitude difference in the crankshaft of the axial vibration mode under consideration, in mm;

d_j — the main journal diameter of the crankshaft, in mm;

$[\Delta_{a0}]$ — the maximum allowable difference between crank webs, in mm;

R — radius of the crank, in mm.

12.3.3.2 Allowable axial vibration amplitudes for transient running are in general, to be 1.5 times those for continuous running.

12.3.3.3 Where allowable values for continuous running are exceeded, restricted speed ranges are to be imposed. Generally, axial vibration amplitudes caused by resonance or the upper flank at r = 0.85 are not to exceed the allowable values for continuous running, and those caused by resonance or the lower flank at r = 1.0 are not to exceed the allowable values for continuous running.

12.3.3.4 Where data from experience or detailed calculations are furnished by manufacturers, allowable axial vibration amplitudes as supplied by the manufacturers may be adopted.

Section 4 WHIRLING VIBRATION

12.4.1 *General requirements*

12.4.1.1 For main propulsion shafting systems, the ship-builders and designers are to ensure, so far as practicable, that excessive amplitudes due to whirling vibration throughout the speed range are not to occur. Otherwise, restricted speed ranges are to be imposed or suitable means for frequency modulation are to be provided as appropriate.

12.4.1.2 For the propulsion shafting systems with brackets and cardan shafts, details of the whirling vibration characteristics are to be submitted for approval.

12.4.2 *Whirling vibration calculations*

12.4.2.1 Whirling vibration calculations are to include: engine type, rated power, rated speed, speed ratio (where applicable), shafting arrangement, lengths and positions of bearings, bearing materials, propeller mass and inertia, the resonant speed of 1 order and blade orders forward and backward whirling vibrations.

12.4.2.2 During whirling vibration calculation, bearing stiffness are to be taken into account, and the load distribution on bearings is also to be considered.

12.4.3 *Speed ranges to be avoided*

12.4.3.1 For the shafting systems with brackets and cardan shafts, the blade order forward whirling resonant speeds are not to appear in the range of r = 0.85 to 1.0, and 1 order forward whirling resonant speeds are to be 20% more than the rated speed.

Section 5 SHAFTING ALIGNMENT

12.5.1 *General requirements*

12.5.1.1 The alignment of main propulsion shafting systems is to comply with the requirements of this Section. For shafting systems using environmentally acceptable lubricants, the alignment of shafting systems is to additionally comply with the requirements of Chapter 4 of the Guidelines for Surveys on Implementation of the Requirements of U.S. Environmental Protection Agency on Environmentally Acceptable Lubricants.

12.5.1.2 The alignment of main propulsion shafting systems and the arrangement of bearings are to be such as to give reasonable bending moments and bearing reactions and minimize the effects of hull deformation or bearing weardown on shafting alignment.

12.5.1.3 For the shafting alignment of large ships, the effects of hull deformation when the ship is ballasted or fully loaded are to be taken into consideration.

12.5.1.4 Shafting alignment calculations together with shafting instructions for the following main propulsion shafting systems are to be submitted for approval:
(1) shafting systems where the propeller shaft has a diameter (hereinafter referred to as propeller shaft diameter) of 250 mm or greater in way of the aftermost sterntube bearing;
(2) shafting systems fitted with no sterntube forward bearing where the propeller shaft diameter is 200 mm or greater;
(3) shafting systems with speed reduction gear, of which the wheel is driven by two or more than two pinions;
(4) shafting systems for which the sterntube bearings are to be slope-bored or inclined;
(5) shaft generator or electrical motor as an integral part of the low speed shaft in diesel engine propulsion.
12.5.1.5 Shafting alignment instructions are to correctly reflect the calculation results for the alignment in cold condition, containing at least the contents of 12.5.4 and 12.5.5 of this Section.
12.5.1.6 In respect to shafting systems where the propeller shaft diameter is less than 250 mm, shafting alignment calculations are in general to be submitted for reference.

Where shafting alignment calculations are not submitted, the span of bearings etc. are to be included in the shafting strength calculations required by subparagraph 11.1.4.1(4), Chapter 11 of this PART, referring to the relevant requirements for shafting alignment in Chapter 9 of ISC Guidelines for Shipboard Vibration Control. In addition, the technological documents submitted by the shipyard regarding shafting alignment are to contain alignment instructions.

12.5.2 *Shafting alignment calculations*

12.5.2.1 Shafting alignment calculation results are to comply with the requirements of 12.5.3.
12.5.2.2 For a propulsion shafting system directly driven by a diesel engine, shafting alignment calculations are generally to be performed up to the 1st main bearing at the free end of the engine. For a gear-driven shafting system, shafting alignment calculations are to be performed up to the fore end of the gear wheel.
12.5.2.3 In shafting alignment calculations, the influence of thermal expansion of heated bearings (e.g. 55℃) during operation of the engine or gearbox and so far as possible, the influence of expansion of heated tanks (e.g. 45℃) in double bottom that are located below intermediate shaft bearings, are to be taken into account.
12.5.2.4 In shafting alignment calculations, the influence of different ambient temperatures (taken as 0℃, 10℃ or 20℃) on the installation of shafting systems is to be taken into account so far as practicable.
12.5.2.5 Shafting alignment calculations are to include engine type, rated power, rated speed, shafting arrangement, all point loads and their acting positions, positions and lengths of bearings, allowable bending moments and shearing forces at the output flange of diesel engines, allowable loads of individual bearings, bearing clearances, relative slope between the propeller shaft and the aftermost sterntube bearing, gearbox information and allowable load difference between fore and aft bearings of the gear wheel.
12.5.2.6 The shaft deflection, the bending moments or stresses, shear forces, and angles at different shaft sections, the loads and reaction force influence numbers of bearings obtained during reasonable shafting alignment in both cold and hot conditions are to be submitted. For shafting systems where the propeller shaft has a diameter of 500 mm or greater, or the design of multi-slope aftermost sterntube bearing is used, the shaft deflection, relative angle and bearing loads at the zero rudder angle as a minimum under rated speed are to be provided, taking into account hydrodynamics of propellers. The calculation results are to comply with the requirements of 12.5.3.2 and 12.5.3.7.
12.5.2.7 A bearing load measurement procedure is to be submitted, covering actual measurements, jacking positions and jack correction factors.
12.5.2.8 The sag and gap values of each couple of flanges for the installation of shafting systems (shaft flanges being not connected) are to be provided.
12.5.2.9 For slope-bored sterntube bearings or bearing inclinations, a detailed description of slope bores or bearing inclinations is to be provided.

12.5.3 *Shafting alignment requirements*

12.5.3.1 In the static condition, all bearing loads are to be positive, i.e. there is to be no voidable bearing load. The bearing load is generally not to be less than 20% of the sum of all weights between two adjacent spans.
12.5.3.2 Bearing loads are in general not to exceed the values specified below or by the manufacturer:
aftermost sterntube bearings: as specified in 11.2.5.1, Chapter 11 of this PART;
sterntube forward bearings: 0.8 N/mm^2;
nonmetallic sterntube bearings: 0.3 N/mm^2;

intermediate shaft bearings: 0.8 N/mm^2;
gear shaft bearings: 1 N/mm^2;
main bearings of diesel engines: as specified by the engine manufacturer.

12.5.3.3 Additional bending stresses of shafts are generally not to exceed the following values:
propeller shafts and sterntube shafts: 20 N/mm^2;
intermediate shafts: 20 N/mm^2;
thrust shafts: 15 N/mm^2;
gear wheel shafts: 10 N/mm^2 or as specified by the gearbox manufacturer.

12.5.3.4 The bending moments and shearing forces applied to the output flange of diesel engines are not to exceed those as specified by the engine manufacturer (if required). The minimum load of main bearings of main engines is in general not to be less than 10% of the allowable load on main bearings. Alternatively, the minimum value specified by the engine manufacturer may be accepted, but this is to be reflected in shafting alignment calculations.

12.5.3.5 The load difference between fore and aft bearings of the gear wheel of the gearbox is to meet the relevant requirements of the manufacturer, generally not exceeding 20% of the sum of the weight of the shaft portion between the two bearings and that of the gear wheel.

Where the alignment calculation results in running condition are provided and the bearing structure is confirmed to be determined according to the acting angle of the resultant force in the running condition, the load difference between fore and aft bearings may not be limited to 20% as specified above provided that the relevant requirements of Appendix 1, Chapter 10 of this PART are complied with.

12.5.3.6 The relative angle between the propeller shaft and the aftermost sterntube bearing at the supporting point of the bearing is not to exceed 3.0×10^{-4} rad in the static condition.

12.5.3.7 For shafting systems where the propeller shaft has a diameter of 500 mm or greater, or the design of multi-slope aftermost sterntube bearing is used, the relative angle between the propeller shaft and the aftermost sterntube bearing at the supporting point of the bearing is not to exceed 3.0×10^{-4} rad in the static condition and in the running condition considering hydrodynamics of propellers. Alternative recognized model technology may be accepted, e.g. multi-point support bearing model or fluid structure three dimensional FE model of interaction between bearing oil film and rotating shaft. Appropriate assumption and recognized modelling methods are to be indicated in the submitted report. The calculated oil film thickness in each analytical condition is not to be less than the minimum thickness value established for the oil film. Such criteria may replace aftermost bearing relative angle criteria.

12.5.4 *Conditions for shafting alignment*

12.5.4.1 The ship's superstructures, main engines, boilers, generators and other pieces of essential equipment are to have been hoisted to their respective places. There is to be no movement of essential equipment or change of ballasting during the alignment, installation and inspection on board.

12.5.4.2 The processing and welding of hull portions within shafting areas are to have been completed.

12.5.4.3 The temperatures of hull structures are to be stable and so far as practicable, uniform.

12.5.4.4 The installation of sterntube arrangements has been completed.

12.5.4.5 Where the ship is afloat, consideration is to be given to measures for preventing movement or rotation of the propeller shaft.

12.5.4.6 Where the ship is in a normal floating condition, the immersion of the propeller is to be so close as practicable to that indicated in calculations.

12.5.5 *Shafting alignment procedure*

12.5.5.1 Where the conditions specified in 12.5.4 are met, shafting alignment may be performed according to the approved alignment calculations or alignment technology (as specified in 12.5.1.4 or 12.5.1.6).

12.5.5.2 Where any noncompliance with calculation conditions (e.g. the ambient temperature, propeller immersion, ship's condition, load adjustment of main bearings of engines) may affect the alignment results during the installation of shafting systems, the alignment calculations together with alignment instructions are to be resubmitted for approval, unless such effects have been included in the calculations.

12.5.5.3 The shipyard is to give full consideration to the influence of deflection of boring equipment on the machining precision of stern tubes. After finishing machining of stern tubes, sizes of bores on stern tubes are to be measured to confirm the deviation of center lines of the stern tube body. Such deviation is to be taken into consideration during cylindrical grinding of stern bearing and compensation during machining is to be made for deviation from stern tube center line as appropriate.

12.5.5.4 After stern bearing is pressed and fitted, slope at stern bearing is to be measured. After the integrated stern tubes are poured and installed, slope at stern bearing is to be measured.

12.5.5.5 Where the load of the sterntube forward bearing is not positive for unconnected shafting flanges, the force applied downward from the propeller shaft forward flange is to comply with the calculations.

12.5.5.6 The axial distance of temporary supports, if fitted, is to comply with the calculations.

12.5.5.7 For shafting alignment, the propeller shaft forward flange is to be used as the reference for positioning bearings or temporary supports and the engine (or gearbox) from aft to fore by adjusting the sag and gap of unconnected flange pairs, in compliance with the relevant requirements.

12.5.5.8 The sag and gap tolerances of flange pairs for straight alignment shafting are to comply with the requirements of 12.5.6.1 and to be recorded.

12.5.5.9 The sag and gap values of flange pairs for the reasonable alignment shafting are to comply with the shafting alignment calculations and tolerances are to comply with the requirements of 12.5.6.1. After connection of flanges, at least a load verification is to be carried out on stern tube forward bearing (if any), intermediate bearing, last three bearings of the main engine (direct transmission propulsion system), wheel shaft bearing (if any) with the ship afloat, and tolerances are to comply with the requirements of 12.5.6.2 and appropriate records are to be made.

12.5.5.10 At the time of completing the shafting alignment, the gear engagement is to be examined or the difference between crank webs of engine measured, and the results are to comply with the requirements of 12.5.6.3 or 12.5.6.4 and appropriate records are to be made.

12.5.5.11 After completion of shafting alignment, coupling bolts are to be provided to flanges, chocks provided or epoxy resin cast to diesel engines (or gearboxes) and engine foundation bolts provided, followed by connection and fixing.

12.5.6 *Shaft alignment survey*

12.5.6.1 The sag and gap of flange pairs are to be examined, with tolerances generally not exceeding ±0.08 mm.

12.5.6.2 Where shafting alignment calculations are applied, actual bearing loads in cold condition may generally be measured by jacking up the loads. The jacking positions are to be the same as specified in calculations. Any deviation of measured loads from calculated ones is not to exceed 20% of the latter. For excessive tolerances, shafting alignment calculations may be carried out according to the measurement results which may be accepted where other requirements of 12.5.3 are still complied with. However, at least the loads of main bearings of the main engine are to be positive.

12.5.6.3 The gear engagement of gear-driven shafting systems is to be examined and the relevant requirements of the gearbox manufacturer are to be complied with.

12.5.6.4 For shafting systems directly driven by the diesel engine, the difference between crank webs of engine are to be examined and the relevant requirements of the engine manufacturer are to be complied with.

Appendix 1 ENHANCED SHAFT ALIGNMENT

1 *General Provisions*

1.1 Application

1.1.1 This Appendix applies to bearings which are white-metal lined and oil lubricated, and ships applying for enhanced shaft alignment (ESA) notation.

2 *Calculation Conditions*

2.1 When carrying out assessment of reasonable shafting alignment, the following calculation conditions are at least to be considered:

(1) ballast condition in both cold and hot conditions (empty tank and full tank are to be considered for aftpeak tank used as ballast tank); 3-5 (2) full load condition in both cold and hot conditions;

(3) ballast condition taking into account hydrodynamic propeller loads (zero rudder angle and full rudder angle under rated speed);

(4) full load condition taking into account hydrodynamic propeller loads (zero rudder angle and full rudder angle under rated speed).

3 *Hull Deflections*

3.1 Hull deflections are to be obtained by means of FE calculation or measurement data of similar ships (same type, similar ship size, similar double bottom height in engine room, similar sterntube and stern arrangement), and other recognized calculation methods.

3.2 Hull deflections in way of bearing position in the following conditions are to be provided:

(1) floating condition;

(2) ballast condition (empty tank and full tank are to be considered for aftpeak tank used as ballast tank);

(3) full load condition.

4 *Hydrodynamic Propeller Loads*

4.1 Hydrodynamic propeller loads may be obtained by means of calculation or empirical data.

4.2 In case the data of 4.1 is unavailable, hydrodynamic propeller loads may be selected in accordance with Table 4.2.

Hydrodynamic Propeller Loads *Table 4.2*

	Zero rudder angle	Full rudder angle
Single screw propulsion	-5% of Q +30% of Q	-30% of Q
Twin screw propulsion	+/-20% of Q	-40% of Q

Note: Q is rated torque;

Positive sign (+) implies upward bending moment;

Negative sign (-) implies downward bending moment.

5 *Aftermost Sterntube Bearing Contact Analysis*

5.1 The relative angle between the propeller shaft and the aftermost sterntube bearing at the supporting point of the bearing is not to exceed 3.0×10^{-4} rad in the static condition and in the running condition considering hydrodynamics of propellers. Alternative recognized model technology may be accepted, e.g. multi-point support bearing model or fluid structure three dimensional FE model of interaction between bearing oil film and rotating shaft. Appropriate assumption and recognized modelling methods are to be indicated in the submitted report. The calculated oil film thickness in each analytical condition is not to be less than the minimum thickness value established for the oil film. Such criteria may replace aftermost bearing relative 3-6 angle criteria.

6 *Criteria*

6.1 The calculation results of calculation conditions (1) and (2) in paragraph 2 of this Appendix are to satisfy applicable requirements of 12.5.3.1 to 12.5.3.6 of this Chapter.

6.2 The bearing load calculation results of calculation conditions (3) and (4) in paragraph 2 of this Appendix are to satisfy applicable requirements of 12.5.3.2 of this Chapter, and there is to be no voidable bearing load. The aftermost bearing relative angle is to satisfy applicable requirements of paragraph 5 of this Appendix.

7 *Survey*

7.1 The bearing actual load in cold or hot ballast conditions (empty tank and full tank are to be considered for aftpeak tank used as ballast tank) corresponding to the calculations may be generally measured by means of jack-up tests. The jack-up position is to be the same as the calculations. The actual load is to comply with provisions for bearing loads in 12.5.3.2.

CHAPTER 13 STEERING GEAR AND WINDLASSES

Section 1 STEERING GEAR

13.1.1 *General requirements*

13.1.1.1 The requirements of this Section apply to steering gear of vessel.

13.1.1.2 The certificate requirements and product survey of steering gear are to comply with relevant requirements in Chapter 3, PART ONE of the Rules.

13.1.2 *Definitions*

13.1.2.1 For the purpose of this Section:

(1) **Main steering gear** is the machinery, rudder actuators, the steering gear power units, if any, and ancillary equipment and the means of applying torque to the rudder stock (e.g. tiller or quadrant) necessary for effecting movement of the rudder for the purpose of steering the ship under normal service conditions.

(2) **Auxiliary steering gear** is the equipment other than any part of the main steering gear necessary to steer the ship in the event of failure of the main steering gear but not including the tiller, quadrant or components serving the same purpose.

(3) *Steering gear power unit is:*

① **in the case of electric steering gear**, an electric motor and its associated electrical equipment;

② **in the case of electro-hydraulic steering gear**, an electric motor and its associated electrical equipment and connected pump;

③ **in the case of other hydraulic steering gear**, a driving engine and connected pump.

(4) **Power actuating system** is the hydraulic equipment provided for supplying power to turn the rudder stock, comprising a steering gear power unit or units, together with the associated pipes and fittings, and a rudder actuator. The power actuating systems may share common mechanical components, i.e. tiller, quadrant and rudder stock, or components serving the same purpose.

(5) **Rudder actuator** is the component which converts directly hydraulic pressure into mechanical action to move the rudder.

(6) **Steering gear control system** is equipment by which orders are transmitted from the navigating bridge to the steering gear power units. Steering gear control systems comprise transmitters, receivers, hydraulic control pumps and their associated motors, motor controllers, piping and cables. Steering gear control system also covers the equipment required to control the steering gear power actuating system.

(7) **Maximum ahead service speed** is the greatest speed which the ship is designed to maintain in service at sea at her deepest seagoing draught at maximum propeller RPM and corresponding engine MCR.

(8) **Maximum astern speed** is the speed which it is estimated the ship can attain at the designed maximum astern power at the deepest sea-going draught.

(9) **Maximum working pressure** is the maximum expected pressure in the system when steering gear is operated to comply with 13.1.5.2(1) of this Section.

(10) **Declared steering angle limits** are the operational limits in terms of maximum steering angle of propulsion and steering systems other than traditional arrangements for a ship's directional control (e.g. azimuth propulsion arrangements or water jet propulsion systems, but not limited to them), or equivalent, according to the manufacturer's guidelines for safe operation, also taking into account the ship's speed or propeller torque/speed or other limitation; the declared steering angle limits are to be declared by the directional control system manufacturer for each ship specific non-traditional steering means.

(11) **Hydraulic locking** are all situations where two hydraulic systems (usually identical) oppose each other in such a way that it may lead to loss of steering. It can either be caused by pressure in the two hydraulic systems working against each other or by hydraulic "bypass" meaning that the systems puncture each other and cause pressure drop on both sides or make it impossible to build up pressure.

13.1.3 *Plans and documents*

13.1.3.1 The following plans and documents are to be submitted for approval:

(1) details of steering gear construction, including documents of strength calculations for principal component parts and materials selected etc.;

(2) steering gear hydrostatic power system, including documents of relief valve's setting and delivery capacity etc.;

(3) power supply system;

(4) control, monitoring alarm system.

13.1.4 *Materials*

13.1.4.1 All the steering gear components such as hydraulic cylinders, pressure housings of rotary vane type actuators, hydraulic power piping valves, flanges and fittings, and all components transmitting mechanical forces to the rudder stock (such as tillers, quadrants, or similar components) are to be of steel or other ductile material, duly tested in accordance with the requirements of ISC Rules for Materials and Welding. In general, such material is not to have an elongation of less than 12% nor a tensile strength in excess of 650 N/mm^2.

If reliable basis for use and relevant background information can be provided, grey cast iron may be accepted for redundant parts with low stress levels, excluding cylinders.

13.1.4.2 Where flexibility is required, approved hose assemblies are to be installed between two points where torsional deflection (twisting) is not subjected to under normal operating conditions. In general, the hose is to be limited to the length necessary to provide for flexibility and for proper operation of machinery.

13.1.4.3 Hose assemblies are to be high pressure hydraulic hose fabricated according to the requirements of Chapter 2 of this PART and suitable for fluids, pressures, temperatures and relevant ambient conditions for which they intend.

13.1.4.4 Burst pressure of hoses is not to be less than four times the design pressure.

13.1.5 *Basic performance*

13.1.5.1 Unless the main steering gear is in compliance with 13.1.5.6 or 13.1.10.1, every ship is to be provided with a main steering gear and an auxiliary steering gear. The main steering gear and the auxiliary steering gear are to be so arranged that the failure of one of them will not render the other one inoperative.

13.1.5.2 The main steering gear and rudder stock is to be:

(1) of adequate strength and capable of putting the rudder over from 35° on one side to 35° the other side with the ship at its deepest seagoing draught and running ahead at maximum ahead service speed and under the same conditions, from 35° either side to 30° the other side in not more than 28 s. For the propulsion and steering systems other than traditional arrangements for a ship's directional control, the main steering arrangements (equivalent to the main steering gear) are to be capable of changing direction of the ship's directional control system from one side to the other at declared steering angle limits at an average rotational speed of not less than 2.3°/s with the ship running ahead at the maximum ahead service speed;

(2) operated by power where manual operation cannot meet the requirements above or in any case when, excluding strengthening for navigation in ice, a rudder stock is over 120 mm diameter in way of the tiller. For the propulsion and steering systems other than traditional arrangements for a ship's directional control, the main steering arrangements are to be operated by power;

(3) so designed that they will not be damaged at maximum astern speed; however, this design requirement need not be proved by trials at maximum astern speed and maximum rudder angle.

13.1.5.3 The auxiliary steering gear is to be:

(1) of adequate strength and capable of steering the ship at navigable speed and of being brought speedily into action in an emergency;

(2) capable of putting the rudder over from 15° one side to 15° the other side in not more than 60 s with the ship at its deepest seagoing draught and running ahead at one half of the maximum ahead service speed or 7 knots, whichever is the greater. For the propulsion and steering systems other than traditional arrangements for a ship's directional control, the auxiliary steering arrangements (equivalent to the auxiliary steering gear) are to be capable of changing direction of the ship's directional control system from one side to the other at declared steering angle limits at an average rotational speed of not less than 0.5°/s; with the ship running ahead at one half of the maximum ahead service speed or 7 knots, whichever is the greater;

(3) operated by power where manual operation cannot meet the requirements above or in any case when, excluding strengthening for navigation in ice, a rudder stock is over 230 mm diameter in way of the tiller. For the propulsion and steering systems other than traditional arrangements for a ship's directional control, where the propulsion power exceeds 2,500 kW per thruster unit, the auxiliary steering arrangements are to be operated by power.

13.1.5.4 Manually operated gears are only acceptable when the operation does not require an effort exceeding 160 N and their constructions are to ensure that the hand wheels of the gears will not be damaged by counter-forces.

13.1.5.5 Main and auxiliary steering gear power units are to be:

(1) arranged to re-start automatically when power is restored after a power failure;

(2) capable of being brought into operation from a position in the navigation bridge;

(3) in the event of a power failure to any one of the steering gear power units, an audible and visual alarm is to be given in the navigation bridge.

13.1.5.6 Where the main steering gear comprises two or more identical power units, an auxiliary steering gear need not be fitted, provided that:
(1) in a passenger ship, the main steering gear is capable of operating the rudder as required in 13.1.5.2(1) of this Section while any one of the power units is out of operation;
(2) in a cargo ship, the main steering gear is capable of operating the rudder as required in 13.1.5.2(1) of this Section while operating with all power units;
(3) the main steering gear is so arranged that after a single failure in its piping system or in one of the power units the defect can be isolated so that steering capability can be maintained or speedily regained.
13.1.5.7 Steering gears, other than that of the hydraulic type, are to achieve the equivalent standards.
13.1.5.8 Steering gears are to be provided with positive rudder angle limiters. Power-operated steering gears are to be fitted with limit switches or similar devices, for stopping the gear before the rudder stops are reached. These arrangements are to be synchronized with the gear itself and not with the steering gear control.
13.1.5.9 Effective means are to be fitted to the steering gear to keep the rudder steady.

13.1.6 *Construction and design*

13.1.6.1 Pressure cylinders of rudder actuators are to be designed in accordance with the relevant requirements of Chapter 6 of this PART for Class I pressure vessels, in addition to provisions of 13.1.10.3 and 13.1.10.4 of this Section. Accumulators, if fitted, are to comply with the relevant requirements of Chapter 6 of this PART.

13.1.6.2 Where the components subject to pressure are designed in accordance with the requirements of 13.1.6.1 of this Section, the permissible primary general membrane stress is not to exceed the lower of the following values:

$$\frac{R_m}{A} \text{ or } \frac{R_{eH}}{B}$$

whichever is less.

where: R_m — specified tensile strength of material at ambient temperature, in N/mm^2;
R_{eH} — specified yield stress or proof stress of the material at ambient temperature, in N/mm^2;
A and B — safety coefficient given by Table 13.1.6.2.

Safety coefficient A or B *Table 13.1.6.2*

Safety coefficient	Steel (except cast steel)	Cast steel	Nodular graphite cast iron
A	3.5	4	5
B	1.7	2	3

13.1.6.3 All welded joints within the pressure boundary of a rudder actuator or connecting parts transmitting mechanical loads are to be full penetration type or of equivalent strength. The welding details and welding procedures are to be subject to approval of ISC.
13.1.6.4 The construction of steering gear components is to be such as to minimize local concentrations of stress.
13.1.6.5 When determining the scantlings of piping and other steering gear components subjected to internal hydraulic pressure, the design pressure is to be at least equal to the greater of the following:
(1) 1.25 times the maximum working pressure;
(2) the relief valve setting.
13.1.6.6 All the steering gear components and the rudder stock are to be of sound and reliable construction. Any essential component which is not duplicated, where appropriate, is to use anti-friction bearings such as ball bearings, roller bearings or sleeve bearings which are to be permanently lubricated or provided with lubrication fittings.
13.1.6.7 All steering gear components transmitting mechanical forces to the rudder stock, which are not protected against overload by structural rudder stops or mechanical buffers, are to have a strength at least equivalent to that of the rudder stock in way of the tiller.
13.1.6.8 Oil seals between non-moving parts forming part of the external pressure boundary are to be of the metal upon metal type or of an equivalent type.
Oil seals between moving parts forming part of the external pressure boundary are to be duplicated, so that the failure of one seal does not render the actuator inoperative. Alternative arrangements providing equivalent protection against leakage may be accepted.
13.1.6.9 Pipes, joints, valves, flanges and other fittings are to comply with the requirements for Class I piping in Chapter 2 of this PART. The design pressure is to be in accordance with 13.1.6.5.

13.1.6.10 For relevant requirements to rudder, rudder stock, tiller and quadrant, refer to Chapter 3, PART TWO of the Rules.

13.1.7 *Hydraulic system*

13.1.7.1 Pipes, joints, valves, flanges and other fittings in hydraulic piping of hydraulic power steering gear are to comply with the requirements for Class I piping in Chapter 2 of this PART. The design pressure is to be in accordance with 13.1.6.5.

13.1.7.2 Relief valves

(1) Relief valves are to be fitted to any part of the hydraulic system which can be isolated and in which pressure can be generated from the power source or from external forces. The setting of the relief valves is not to exceed the design pressure. The valves are to be of adequate nominal diameter and so arranged as to avoid an undue rise in pressure above the design pressure.

(2) Relief valves fitted as required in 13.1.7.2(1) are to comply with the following:

① the setting pressure is not to be less than 1.25 times the maximum working pressure;

② the minimum discharge capacity of the relief valve(s) is not to be less than 110% of the total capacity of the pumps which can deliver through it (them).

Under such conditions the rise in pressure is not to exceed 10% of the setting pressure. In this regard, due consideration is to be given to extreme foreseen ambient conditions in respect of oil viscosity.

13.1.7.3 Isolating valves

For rudder actuators with non-duplicated units, isolating valves are to be fitted at the connection of pipes to the hydraulic cylinders, and are to be directly fitted on the hydraulic cylinders.

13.1.7.4 Filters

Arrangements to maintain the cleanliness of the hydraulic fluid are to be provided taking into consideration the type and design of the hydraulic system.

13.1.7.5 Level alarm

A low level alarm is to be provided for the circulating oil tank of each hydraulic system to give the earliest practicable indication of hydraulic fluid leakage. Audible and visual alarms are to be given in the navigation bridge and in the machinery space where they can be readily observed.

13.1.7.6 Arrangements for bleeding air

Arrangements for bleeding air from the hydraulic system are to be provided, where necessary.

13.1.7.7 Hydraulic locking

Where the steering gear is so arranged that more than one system (either power or control) can be simultaneously operated, the risk of hydraulic locking caused by single failure is to be considered.

13.1.7.8 Storage tank

A fixed storage tank having sufficient capacity to recharge at least one power actuating system including the circulating oil tank is to be provided, where the main steering gear is required to be power operated. The storage tank is to be permanently connected by piping in such a manner that the hydraulic systems can be readily recharged from a position within the steering gear compartment and provided with a content gauge.

13.1.7.9 Arrangement

The power piping for hydraulic steering gears is to be so arranged that transfer between units can be readily effected.

13.1.8 *Power supply and control systems*

13.1.8.1 Steering gear control is to be provided:

(1) for the main steering gear, both in the navigation bridge and in the steering gear compartment;

(2) where the main steering gear is arranged according to 13.1.5.6 of this Section, by two independent control systems, both operable from the navigating bridge. This does not require duplication of the steering wheel or steering lever. Where the control system consists of a hydraulic telemotor, a second independent system need not to be fitted, except in a tanker of 10,000 gross tonnage and upwards, a chemical carrier or a liquefied gas carrier;

(3) for the auxiliary steering gear, in the steering gear compartment and, if power operated, it is also to be operable from the navigating bridge and is to be independent of the control system for the main steering gear.

13.1.8.2 Main and auxiliary steering gear control systems operable from the navigating bridge are to comply with the following:

(1) Means are to be provided in the steering gear compartment for disconnecting any control system operable from the navigating bridge from the steering gear it serves.

(2) The system is to be capable of being brought into operation from a position in the navigation bridge.

13.1.8.3 The angular position of the rudder is to be:

(1) if the main steering gear is power operated, indicated in the navigation bridge. The rudder angle indication is to be independent of the steering gear control system;

(2) recognizable in the steering gear compartment.

13.1.8.4 Where applicable, following standard signboard is to be fitted at a suitable place on steering control position in the bridge or incorporated into operating instruction mentioned in 13.1.11.3 of this Section.

"Caution:

In Some Circumstances When Two Power Units Are Running Simultaneously the Rudder May Not Respond to Helm. If This Happens Stop Each Pump in Turn Until Control Is Regained."

The above signboard is related to steering gears provided with two identical power units intended for simultaneous operation, and normally provided with either their own control systems or two separate (partly or mutually) control systems which are/may be operated simultaneously.

13.1.8.5 Source of electrical power and cable installation

(1) Means for indicating that motors of electric and electrohydraulic steering gear are running is to be installed in the navigation bridge and at a suitable main machinery control position.

(2) Each electrical or electrohydraulic steering gear comprising one or more power units is to be served by at least two exclusive circuits fed directly from the main switchboard, however, one of the circuits may be supplied through the emergency switchboard. Each power unit of electrical or electrohydraulic main steering gear complying with the requirements of 13.1.5.6 of this Section is to be served by one exclusive circuit fed directly from the main switchboard, and one of the afore-mentioned circuits may be fed from the emergency switchboard. An auxiliary electric or electrohydraulic steering gear associated with a main electrical or electrohydraulic steering gear may be connected to one of the circuits supplying this main steering gear. The circuits supplying an electrical or electrohydraulic steering gear are to have adequate rating for supplying all motors which can be simultaneously connected to them and may be required to operate simultaneously.

(3) When in a ship of less than 1,600 gross tonnage an auxiliary steering gear which is required in 13.1.5.3(3) of this Section to be operated by power is not electrically powered or is powered by an electrical motor primarily intended for other services, the main steering gear may be fed by one circuit from the main switchboard.

(4) Each main and auxiliary steering gear control system, if electrical and operable from the navigating bridge, is to be served by its own separate circuit supplied from a steering gear power circuit from a point within the steering gear compartment. Or alternatively, this control system may be supplied by a separate circuit directly from the same section of main or emergency switchboard bus-bars at a point on the switchboard adjacent to that supplying the said steering gear power circuit. For above-mentioned main and auxiliary steering gear, short circuit protection is only to be provided for power circuits of control system.

(5) The electrical power circuits and the steering gear control systems with their associated components, cables and pipes required in this Section are to be separated as far as practicable throughout their length.

13.1.8.6 Where the rudder stock is required to be over 230 mm diameter in way of the tiller (excluding strengthening for navigation in ice), or where the propulsion power exceeds 2,500 kW per thruster unit (applying to propulsion and steering systems other than traditional arrangements for a ship's directional control), an alternative power supply, sufficient at least to supply the steering gear power unit or the steering arrangements which complies with the requirements of 13.1.5.3(2) of this Section and also its associated control system and the rudder angle indicator, is to be provided automatically, within 45 s, either from the emergency source of electrical power or from an independent source of power located in the steering gear compartment. This independent source of power is to be used only for this purpose. In every ship of 10,000 gross tonnage and upwards, the alternative power supply is to have a capacity for at least 30 min of continuous operation and in any other ship for at least 10 min.

13.1.8.7 Where the alternative power source for steering gear is an independent engine driven hydraulic pump located in the steering gear compartment, automatic starting arrangements for the engine are to comply with the relevant requirements relating to the automatic starting arrangements of emergency generators.

13.1.9 *Monitoring and alarms*

13.1.9.1 The alarm and monitoring requirements for the steering gear are to be in accordance with Table 13.1.9.1 and comply with the relevant requirements of Section 4, Chapter 2, PART SEVEN of the Rules. The failures likely to cause uncontrolled movements of rudder as indicated in the Table below are to be clearly identified. In the event of detection of such failure, the rudder is to stop in the current position without manual intervention or is to return to the midship/neutral poistion. For mechanical failures such as

sticking valves and failure of static components (pipes, cylinders), the system response without manual intervention is not mandatory, and the operator can follow instructions on the signboard in case of such failures, in accordance with the relevant requirements of 13.1.8.4 of this Section.

Alarm and Monitoring Requirements *Table 13.1.9.1*

No.	Item	Alarm and monitoring	Location	Note
1	Steering gear power unit	Power supply failure	Navigation bridge	–
2	Steering gear circuit and motor	Broken connections and overload	Navigation bridge and main control position in engine room	–
3	Steering gear motor	Indication of running		
4	Steering gear control system	Power supply failure	Navigation bridge	–
5		Earth fault on AC and DC circuits		If applicable (e.g. the control system is connected to main power supply through transformer)
6		Loop failures in closed loop systems (short circuit, broken connections and earth faults)		–
7		Data communication errors		If programmable electronic system is used
8		Computer hardware and software failures		
9		Deviation alarm		Deviation alarm is to be initiated if the rudder's actual position does not reach the set point within acceptable time limits for the closed loop control systems (e.g. follow-up control and autopilot). Deviation alarm may be caused by mechanical, hydraulic or electrical failures
10	Hydraulic oil tank of steering gear	Low level	Navigation bridge and machinery space	Each oil tank is to be monitored
11	Angular position of rudder	Rudder angle indication	Navigation bridge and steering gear compartment	See 13.1.8.3
12	Automatic rudder arrangement	Failure	Navigation bridge	—
13		Indication of operation		
14	Hydraulic oil	High temperature	Navigation bridge	If fitted with oil cooler
15	Hydraulic oil filter	High pressure difference	Navigation bridge	If oil filter is fitted
16	Steering gear (power or control) hydraulic system	Hydraulic locking	Navigation bridge	See 13.1.9.5

13.1.9.2 Short circuit protection and an overload alarm are to be provided for the circuits and motors referred to in 13.1.8.5(2) of this Section. Protection against excess current, including starting current, if provided, is to be for not less than twice the full load current of the motor or circuit so protected, and is to be arranged to permit the passage of the appropriate starting currents. Steering gear motor circuits obtaining their power supply via an electronic converter, e.g. for speed control, and which are limited to full load current are exempt from the requirement to provide protection against excess current. The required overload alarm is to be set to a value not greater than the normal load of the electronic converter. Normal load is the load in normal mode of operation that approximates as close as possible to the most severe conditions of normal use in accordance with the manufacturer's operating instructions. Where a three-phase supply is used, an alarm is to be provided that will indicate failure of any one of the supply phases. The alarms required in this Article are to be both audible and visual and are to be situated in a conspicuous position in the main machinery space or control room from which the main machinery is normally controlled. Audible and visual alarms are also required to be provided in the navigation bridge.

13.1.9.3 For any main and auxiliary steering gear control system operable from the navigation bridge an audible and visual alarm is to be given in the navigation bridge in the event of failure of electrical power supply to the control system, or in the event of a power failure to any one of the steering gear power units.

13.1.9.4 When in a ship of less than 1,600 gross tonnage an auxiliary steering gear which is required in 13.1.5.3(3) of this Section is powered by an electrical motor primarily intended for other services, the requirements of 13.1.9.2 of this Section may be waived by ISC if satisfied with protection arrangement together with the requirements of 13.1.5.5

and 13.1.8.1(3) of this Section applicable to auxiliary steering gear.

13.1.9.5 Where hydraulic locking, caused by a single failure, may lead to loss of steering, an audible and visual alarm, which identifies the failed system, is to be provided in the navigation bridge.

The alarm is to be activated whenever:

(1) position of the variable displacement pump control system does not correspond with given order; or

(2) incorrect position of 3-way full flow valve in constant delivery pump system is detected.

13.1.10 *Additional requirements*

13.1.10.1 For every oil tanker, chemical carrier and liquefied gas carrier of 10,000 gross tonnage and upwards, every other ship of 70,000 gross tonnage and upwards the main steering gear is to comprise two or more identical power units complying with the provisions of 13.1.5.6 of this Section.

13.1.10.2 For every oil tanker, chemical carrier and liquefied gas carrier of 10,000 gross tonnage and upwards, subject to the requirements specified in 13.1.10.3, the steering gear is to comply with the following requirements:

(1) The main steering gear is to be so arranged that in the event of loss of steering capability due to a single failure in any part of one of the power actuating systems of the main steering gear, excluding the tiller, quadrant or components serving the same purpose, or seizure of the rudder actuators, steering capability is to be regained within 45 s after the loss of one power actuating system.

(2) The main steering gear is to comprise either:

① two independent and separate power actuating systems, each capable of meeting the requirements of 13.1.5.2(1) of this Section; or

② at least two identical power actuating systems which, acting simultaneously in normal operation, are capable of meeting the requirements of 13.1.5.2(1) of this Section. Where necessary to comply with these requirements, inter-connection of hydraulic power actuating systems is to be provided. Loss of hydraulic fluid from one system is to be capable of being detected and the defective system automatically isolated so that the other actuating system or systems remain fully operational.

(3) Steering gears other than that of the hydraulic type are to achieve equivalent standards.

13.1.10.3 For every oil tanker, chemical carrier and liquefied gas carrier of 10,000 gross tonnage and upwards but of less than 100,000 tons deadweight, solutions other than those set out in 13.1.10.2 of this Section which need not apply the single failure criterion to the rudder actuator or actuators, may be permitted provided that an equivalent safety standard is achieved and that:

(1) following loss of steering capability due to a single failure of any part of the piping system or in one of the power units, steering capability is regained within 45 s;

(2) where the steering gear includes only a single power actuator, stress analysis for the design including fatigue analysis and fracture mechanics analysis, as appropriate, the material used, the installation of sealing arrangements and the testing and inspection and provision of effective maintenance are to be submitted. See Appendix 1 to this Chapter for details.

13.1.10.4 Manufacturers of steering gear who intend their product to comply with the requirements of Appendix 1 of this Chapter are to submit corresponding information for approval by ISC.

13.1.11 *Arrangement*

13.1.11.1 In general, the steering gear is to be reliably secured to the seating with sufficient rigidity by fitting bolts or bolts and thrust plates.

13.1.11.2 The steering gear compartment is to be:

(1) readily accessible and, as far as practicable, separated from machinery spaces;

(2) provided with suitable arrangements to ensure working access to steering gear machinery and controls. These arrangements are to include handrails and gratings or other non-slip surfaces to ensure suitable working conditions in the event of hydraulic fluid leakage.

13.1.11.3 Suitable operating instructions with a block diagram showing the change-over procedures for actuating systems and control systems of steering gear are to be permanently displayed in the navigation bridge and in the steering gear compartments.

13.1.11.4 A means of communication is to be provided between the navigation bridge and the steering gear compartment.

13.1.12 *Testing*

13.1.12.1 Testing at works

(1) The pipes, valves and other parts in hydraulic piping system of hydraulic power steering gear are to comply with the related requirements for class I piping in Chapter 2 of this PART.

(2) The pressure parts designed in accordance with 13.1.6.1 of this Section are to be tested in accordance

with the related requirements for class I pressure vessels in Chapter 6 of this PART.

(3) A hydraulic power unit pump is to be subject to a type test. The type test is to be carried out at workshop for a duration of not less than 100 h according to the following:

① the test arrangements are to be such that the pump may run in idling conditions, and at maximum delivery capacity at maximum working pressure;

② during the test, idling periods are to be alternated with periods at maximum delivery capacity at maximum working pressure. The passage from one condition to another is to occur at least as quickly as on board;

③ during the whole test, no abnormal heating, excessive vibration or other irregularities are permitted;

④ after the test, the pump is to be disassembled and inspected.

Type test may be waived for a power unit which has been proven to be reliable in marine service.

(4) For a diesel engine of a hydraulic power unit, see Chapter 9 of this PART.

(5) For an electric motor of a hydraulic power unit, see Chapter 3, PART FOUR of the Rules.

(6) After testing of each part and completion of general installation, the steering gear is to be subject to the final inspection and operation test.

13.1.12.2 Testing on board

After installation on board the vessel, the hydraulic steering gear is to be subject to a hydraulic tightness test under 1.25 times the design pressure and any kind of steering gear is to be subject to and a running test in mooring condition.

13.1.12.3 Sea trials

The steering gear is to be tried out on sea trial in order to demonstrate satisfaction that the requirements of this Section have been met. The trial is to include the operation of the following:

(1) the steering gear, including demonstration of the performances required in 13.1.5.2(1) and 13.1.5.3(2). If the vessel cannot be tested at the deepest seagoing draught, steering gear trials are to be conducted at a displacement as close as reasonably possible to full-load displacement on either of the following conditions:

① where the rudder is fully submerged (zero speed waterline) and the vessel is in an acceptable trim condition; or

② where the rudder load and torque at the specified trial loading condition have been predicted and extrapolated to the full load condition.

In any case for the main steering gear trial, the speed of ship corresponding to the number of maximum continuous revolution of main engine could apply; for controllable pitch propellers, the propeller pitch is to be at the maximum design pitch approved for the maximum continuous ahead R.P.M. at the main steering gear trial;

(2) the steering gear power units, including transfer between steering gear power units;

(3) the isolation of one power actuating system, checking the time for regaining steering capability;

(4) the hydraulic fluid recharging system;

(5) the emergency power supply required in 13.1.8.6 of this Section;

(6) the steering gear controls, including transfer of control and local control;

(7) the means of communication between the wheelhouse, engine room and the steering gear compartment;

(8) the alarms and indicators required in this Chapter;

(9) where steering gear is designed to avoid hydraulic locking this feature is to be demonstrated.

The trials in (2), (3), (4), (7), (8) and (9) above may be carried out during mooring trial.

Section 2 WINDLASSES

13.2.1 *General requirements*

13.2.1.1 The requirements of this Section apply to windlasses of vessel.

13.2.1.2 The certification requirements and product survey of windlasses are to comply with the relevant requirements in Chapter 3, PART ONE of the Rules.

13.2.1.3 The design, construction and testing of windlasses are to conform to a standard or code of practice accepted by ISC. To be considered acceptable, the standard or code of practice is to specify criteria for stresses, performance and testing. The following are examples of standards recognized:

SNAME T & R Bulletin 3-15: 2018	Guide to the Design and Testing of Anchor Windlasses for Merchant Ships
ISO 7825: 2017	Deck machinery general requirements
ISO 4568: 2021	Shipbuilding - Sea-going vessels - Windlasses and anchor capstans

13.2.2 *Definitions*

13.2.2.1 For the purpose of this Section:

(1) **Working load** means the tension measured at wildcats, and is to be calculated in accordance with 13.2.5.2(1) of this Section.

(2) **Overload pull** means the capability of the windlass necessary to withstand an overload pull for a short time.

(3) **Mean speed** means the speed for raising two lengths of cable chains when three lengths of cable chains are in the water with the anchor hanged free.

(4) **Withstand load** means the maximum static load applied to chain cables which the windlass brake can withstand.

13.2.3 *Plans and documents*

13.2.3.1 The following plans showing the design specifications, the standard of compliance, engineering analyses and details of construction, as applicable, are to be submitted for approval:

(1) windlass arrangement plan showing all of the components of the anchoring/mooring system such as the prime mover, shafting, cable lifter, anchors and chain cables; mooring winches, wires and fairleads, if they form part of the windlass machinery; brakes; controls; etc.;

(2) dimensions, materials, welding details, as applicable, of all torque-transmitting (shafts, gears, clutches, couplings, coupling bolts, etc.) and all load bearing (shaft bearings, cable lifter, sheaves, drums, bed-frames, etc.) components of the windlass and of the winch, where applicable, including brakes, chain stopper (if fitted) and foundation;

(3) hydraulic system, to include: piping diagram along with system design pressure; safety valves arrangement and settings; material specifications for pipes and equipment; typical pipe joints, as applicable; and technical data and details for hydraulic motors;

(4) electric one line diagram along with cable specification and size; motor controller; protective device rating or setting; as applicable;

(5) control, monitoring and instrumentation arrangements;

(6) engineering analyses for torque-transmitting and load-bearing components demonstrating their compliance with recognized standards or codes of practice. Analyses for gears are to be in accordance with a recognized standard;

(7) plans and data for windlass electric motors including associated gears rated 50 kW and over;

(8) calculations demonstrating that the windlass prime mover is capable of attaining the hoisting speed, the required continuous duty pull, and the overload capacity are to be submitted if the “load testing” including “overload” capacity of the entire windlass unit is not carried out at the shop (see 13.2.6.1).

13.2.3.2 The following plans and documents are to be submitted for information:

(1) windlass design specifications; anchor and chain cable particulars; anchorage depth; performance criteria; standard of compliance;

(2) operation and maintenance procedures for the anchor windlass are to be incorporated in the vessel operations manual.

13.2.4 *Material and welding*

13.2.4.1 The materials for parts which are stressed by the pull of the chain when the cable lifer is disengaged (e.g. main shaft, driving gear, cable lifter, chain pulley, brake spindle, etc.) are generally to be made of steel. If chain cable passes through stopper, stopper is to be made of ductile material. Testing of material is to comply with the requirements of ISC Rules for Materials and Welding.

13.2.4.2 Materials used in the construction of torque-transmitting and load-bearing parts of windlasses and the testing of the materials are to comply with the requirements of ISC Rules for Materials and Welding. The proposed materials are to be indicated in the construction plans and are to be approved in connection with the design. All such materials are to be certified by the material manufacturers.

13.2.4.3 Weld joint designs are to be shown in the construction plans and are to be approved in association with the approval of the windlass design. Welding procedures and welders are to be qualified in accordance with the requirements of ISC Rules for Materials and Welding. Welding consumables are to be approved by ISC in the case they fall within the scope of ISC Rules for Materials and Welding; when they fall outside the scope of ISC Rules for Materials and Welding, they are to comply with national or international standards. The degree of non-destructive examination of welds and post-weld heat treatment, if any, are to be specified and submitted to ISC for consideration.

13.2.5 *Design and requirements*

13.2.5.1 Driving type

Windlasses are to be driven by prime movers or motors independent from other deck machinery. For hydraulic windlasses, the hydraulic pipes may be connected with the pipes for other deck machinery, provided that there is no interference to the operation of windlasses.

Where applicable, hand-operated windlasses may be accepted for ships having anchors of not more than 250 kg, and provision is to be made for prevention of injuring persons by handles.

13.2.5.2 Driving power

Windlasses are to be of sufficient power and are to be capable of working continuously, the working load and overload pull of which are to meet the following requirements:

(1) Windlasses are to be capable of working continuously for a period of 30 min at the mean speed as required in 13.2.6.3 of this Section. In general, stresses in each torque-transmitting component are not to exceed 40% of yield strength (or 0.2% proof stress) of the material under these loading conditions:

① where the design anchorage depth is less than or equal to 82.5 m:

$37.5\ d^2$, N for Class 1 stud link chains;

$42.5\ d^2$, N for Class 2 stud link chains;

$47.5\ d^2$, N for Class 3 stud link chains;

② where the design anchorage depth is greater than 82.5 m:

$37.5\ d^2 + (D - 82.5) \times 0.27\ d^2$, N for Class 1 stud link chains;

$42.5\ d^2 + (D - 82.5) \times 0.27\ d^2$, N for Class 2 stud link chains;

$47.5\ d^2 + (D - 82.5) \times 0.27\ d^2$, N for Class 3 stud link chains;

where: d — chain diameter, in mm;

D — design anchorage depth, in m.

The above working loads are based on the hoisting of one anchor at a time (for anchor weight, refer to the provisions of Section 2, Chapter 3, PART TWO of the Rules), and that the effects of buoyancy and the hawse pipes efficiency (assumed to be 70%) have been accounted for.

(2) Windlasses are to be capable of working continuously for a period of at least 2 min under an overload pull (without any requirements for hoisting speed) for breaking out the anchor. The overload pull is not less than 1.5 times the working load.

13.2.5.3 Other design loads

(1) Holding loads

Calculations are to be made to show that, in the holding condition (single anchor, cable lifter brake fully applied and chain cable lifter declutched), and under a load equal to 80% of the specified minimum breaking strength of the chain cable, the maximum stress in each load bearing component will not exceed yield strength (or 0.2% proof stress) of the material. For installations fitted with a chain cable stopper, 45% of the specified minimum breaking strength of the chain cable may instead be used for the calculation.

(2) Inertia loads

The design of the drive train, including prime mover, reduction gears, bearings, clutches, shafts, cable lifter and bolting is to consider the dynamic effects of sudden stopping and starting of the prime mover or chain cable so as to limit inertial load.

(3) Driving loads

Each transmission component is to be able to withstand the maximum output torque of the prime mover.

13.2.5.4 Reversing equipment

Power-operated windlasses are to be reversible.

13.2.5.5 Clutch

Windlasses are to be provided with a clutch located between the wildcat and driving shaft, and the clutches are to be provided with efficient locking devices. Hydraulically or electrically operated clutches are to be capable of being disengaged manually.

13.2.5.6 Brake

(1) Cable lifter brake

The wildcats or reels of windlasses are to be provided with efficient brakes to stop the anchor and chain cable when paying out the chain cable. The force-bearing parts of the brakes, when fully applied, are to withstand the following loads without permanent deformation and without brake slip.

① For windlasses fitted with a chain stopper, the brake is to be able to withstand a static pull equal to 45% of the breaking load of the cable or wire or the maximum static load of the cable or wire;

② For windlasses not fitted with a chain stopper, the brake is to be able to withstand a static pull equal to 80% of the breaking load of the cable or wire.

(2) Control brake

① Electric windlasses are to be provided with a fail-safe brake mechanism such that the brakes are automatically engaged when the operating device is in the stop or braking position, or when there is no power to the electric motors. The brake is to be able to function automatically and hold a load on the chain cable of 1.5 times the working load of the windlass.

② For other types of drives, a suitable fail-safe brake mechanism is to be used. The brake is to be able to hold a load on the chain cable of 1.3 times the working load of the windlass.

13.2.5.7 Chain cable stopper

Chain cable stopper, if fitted, along with its attachments is to be designed to withstand, without any permanent deformation, 80% of the specified minimum breaking strength of the chain cable.

13.2.5.8 Overload protection

Prime movers and transmission gears are to be provided with means for prevention of excessive moment and impact.

13.2.5.9 Protection of mechanical components

To protect mechanical parts including component housings, a suitable protection system is to be fitted to limit the speed and torque at the prime mover. Consideration is to be given to a means to contain debris consequent to a severe damage of the prime mover due to overspeed in the event of uncontrolled rendering of the cable, particularly when an axial piston type hydraulic motor forms the prime mover.

13.2.5.10 Hydraulic system

Hydraulic system of windlasses is also to comply with the relevant requirements of Section 7 of Chapter 2 and Section 7 of Chapter 4 of this PART.

13.2.5.11 Marking

Windlass is to be permanently marked with the following information:

(1) nominal size of the windlass (e.g. 100/3/45 is the size designation of a windlass for 100 mm diameter chain cable of Grade 3, with a holding load of 45 % of the breaking load of the chain cable);

(2) maximum anchorage depth, in metres.

13.2.5.12 For the strength requirements for anchors, chain cables and securing of windlasses, see the relevant requirements in Section 2, Chapter 3 of PART TWO of the Rules.

13.2.5.13 Electrical systems

(1) Electric motors are to meet the requirements in Section 2, Chapter 3 of PART FOUR of the Rules, and those rated 50 kW and over are to be certified. Motors exposed to weather are to have enclosures suitable for their location as provided for in the requirements in Table 1.3.2.2 of PART FOUR of the Rules. Where gears are fitted, they are to meet the requirements of ISO 6336-6 or other acceptable standards and those rated 100 kW and over are to be certified.

(2) Electric motors are to be protected in accordance with the requirements in 2.5.10 of PART FOUR of the Rules and cable sizing is to be in accordance with the requirements in Section 12, Chapter 2 of PART FOUR of the Rules. Electrical cables installed in locations subjected to the sea are to be provided with effective mechanical protection.

13.2.6 *Testing*

13.2.6.1 Testing at works

(1) The pumps, pipes, valves and fittings in piping system are to comply with the relevant requirements in Chapter 2 of this PART.

(2) For a diesel engine of a hydraulic power unit, see Chapter 9 of this PART.

(3) For an electric motor of a hydraulic power unit, see Chapter 3, PART FOUR of the Rules.

(4) After testing of each part and completion of general installation, the windlass is to be subject to final inspection and functional test to ensure that it complies with the design requirements in 13.2.5 above. Windlasses are to be inspected and witnessed by a Surveyor and include the following tests, as a minimum.

① No-load test

The windlass is to be run without load at nominal speed in each direction for a total of 30 minutes. If the windlass is provided with a gear change, additional run in each direction for 5 minutes at each gear change is required.

② Load test

The windlass is to be tested to verify that the continuous duty pull, overload capacity and hoisting speed as specified in 13.2.5.2 can be attained. For large windlass, where the manufacturing works does not have adequate facilities, load test (including the adjustment of the overload protection) can be carried out on board ship. In these cases, functional testing in the manufacturing works is to be performed under no-load conditions.

③ Brake capacity test.

The holding power of the cable lifter brake is to be verified either through testing or by calculation.

13.2.6.2 Testing on board

After installation on board the vessel, the hydraulic system of the windlass is to be subject to a hydraulic tightness test under 1.25 times the design pressure.

Each windlass is to be tested under working conditions after installation onboard to demonstrate satisfactory operation. Each unit is to be independently tested for braking, clutch functioning, lowering and hoisting of chain cable and anchor, proper riding of the chain over the cable lifter, proper transit of the chain through the hawse pipe and the chain pipe, and effecting proper stowage of the chain and the anchor. It is to be confirmed that anchors properly seat in the stored position and that chain stoppers function as designed if fitted. The braking capacity is to be tested by intermittently paying out and holding the chain cable by means of the application of the brake.

13.2.6.3 Sea trials

(1) In carrying out the trial of hoisting anchor by the windlass, a mean speed of hoisting one anchor from a depth of 82.5 m to a depth of 27.5 m is not to be less than 9 m/min (equivalent to hoisting two shots of chain cable). Where the depth of water in allowable trial areas is inadequate, the deepest sea area in allowable trial areas is to be selected for trial.

(2) Where the design anchorage depth is greater than 82.5 m, the windlass is also to be able to hoist one anchor from the design anchorage depth to a depth of 82.5 m at a mean speed not less than 3 m/min. Where the depth of waters for the anchoring test is not adequate for the design anchorage depth, consideration may be given to accepting an equivalent simulating test.

Appendix 1① GUIDELINES FOR THE ACCEPTANCE OF NON-DUPLICATED RUDDER ACTUATORS FOR TANKERS, CHEMICAL TANKERS AND GAS CARRIERS OF 10,000 GROSS TONNAGE AND UPWARDS BUT OF LESS THAN 100,000 TONS DEADWEIGHT

1.1 *Materials*

1.1.1 Parts subject to internal hydraulic pressure or transmitting mechanical forces to the rudder-stock are to be made of duly tested ductile materials complying with recognized standards. Materials for pressure retaining components are to be in accordance with recognized pressure vessel standards. These materials are not to have an elongation less than 12 per cent nor a tensile strength in excess of 650 N/mm^2.

1.2 *Design*

1.2.1 The design pressure should be assumed to be at least equal to the greater of the following:

(1) 1.25 times the maximum working pressure to be expected under the operating conditions required in 13.1.5.2(1);

(2) the relief valve(s) setting.

1.2.2 Analysis

In order to analyse the design, the following are required:

(1) The manufacturers of rudder actuators should submit detailed calculations showing the suitability of the design for the intended service.

(2) A detailed stress analysis of pressure retaining parts of the actuator should be carried out to determine the stresses at the design pressure.

(3) Where considered necessary because of the design complexity or manufacturing procedures, a fatigue analysis and fracture mechanics analysis may be required. In connection with these analyses, all foreseen dynamic loads should be taken into account. Experimental stress analysis may be required in addition to, or in lieu of, theoretical calculations depending upon the complexity of the design.

1.2.3 Allowable stresses

For the purpose of determining the general scantlings of parts of rudder actuators subject to internal hydraulic pressure, the allowable stresses should not exceed:

$$\sigma_m \le f$$
$$\sigma_l \le 1.5f$$
$$\sigma_n \le 1.5f$$
$$\sigma_l + \sigma_n \le 1.5f$$
$$\sigma_m + \sigma_n \le 1.5f$$

where: σ_m — equivalent primary general membrane stress, in N/mm^2;

σ_l — equivalent primary local membrane stress, in N/mm^2;

σ_n — equivalent primary bending stress, in N/mm^2;

f = the lesser of R_m/A or R_{eH}/B;

R_m — specified minimum tensile strength of material at ambient temperature, in N/mm^2;

R_{eH} — specified minimum yield stress or proof stress of material at ambient temperature, in N/mm^2.

A and B are listed in Table 1.2.3.

Table 1.2.3

Numerical value	Forged steel	Cast steel	Nodular cast iron
A	4	4.6	5.8
B	2	2.3	3.5

1.2.4 Burst test

(1) Pressure retaining parts not requiring fatigue analysis and fracture mechanics analysis may be accepted on the basis of a certified burst test and the detailed stress analysis required in 1.2.2(2) need not be provided.

(2) The minimum bursting pressure is to be calculated as follows:

---

① This Appendix is from the Annex to IMO resolution A.467(XII).

$$P_b = PA(R_{ma}/R_m) \quad \text{MPa}$$

where: P_b — minimum bursting pressure, in MPa;
P — design pressure as defined in 1.2.1, in MPa;
A — selected from Table 1.2.3;
R_{ma} — actual tensile strength, in N/mm^2;
R_m — tensile strength as defined in.1.2.3, in N/mm^2.

1.3 *Construction details*

1.3.1 The construction is to be such as to minimize local concentrations of stress.

1.3.2 The welding details and welding procedures are to be approved.

1.3.3 All welded joints within the pressure boundary of a rudder actuator or connection parts transmitting mechanical loads should be full penetration type or of equivalent strength.

1.3.4 Oil seals forming part of the external pressure boundary are to comply with 13.1.6.8 of this Chapter.

1.3.5 Isolating valves are to be fitted at the connection of pipes to the actuator, and should be directly mounted on the actuator.

1.3.6 Relief valves for protecting the rudder actuator against over-pressure as required in 13.1.7.2 of this Chapter are to comply with the following:

(1) The setting pressure is not to be less than 1.25 times the maximum working pressure expected under operating conditions required in 13.1.5.2(1) of this Chapter.

(2) The minimum discharge capacity of the relief valve(s) is not to be less than 110% of the total capacity of all pumps which provided power for the actuator. Under such conditions the rise in pressure should not exceed 10% of the setting pressure. In this regard due consideration should be given to extreme foreseen ambient conditions in respect of oil viscosity.

1.4 *Non-destructive testing*

1.4.1 The rudder actuator should be subject to suitable and complete non-destructive testing to detect both surface flaws and volumetric flaws.

1.4.2 The procedure and acceptance criteria for non-destructive testing should be in accordance with requirements of recognized standards. If found necessary, fracture mechanics analysis may be used for determining maximum allowable flaw size.

1.5 *Testing*

1.5.1 Tests, including hydrostatic tests, of all pressure parts at 1.5 times the design pressure should be carried out.

1.5.2 When installed on board the ship, the rudder actuator should be subject to a hydrostatic test and a running test.

CHAPTER 14 STRENGTHENING FOR NAVIGATION IN ICE

Section 1 GENERAL PROVISIONS

14.1.1 *General requirements*

14.1.1.1 For ships with ice notations B1*, B1, B2, B3, the machinery installations are to additionally comply with the provisions of this Chapter. For ships with ice notation B, only the requirements of 14.1.1.2 and 14.1.1.4 need to be complied with.

14.1.1.2 For ships with ice notations B1*, B1, B2, B3 and B, the machinery installations are to be capable of assuring safe and normal operation under air temperatures below 0℃. Particular attention is to be paid to the functioning of hydraulic systems, anti-freezing of water piping and tanks, starting of emergency diesels at low temperatures.

14.1.1.3 The strengthening requirements for ice notations B1*, B1, B2 and B3 correspond respectively to the relevant provisions in the Finish-Swedish Ice Class Rules, 2021, as follows:

B1* — IA Super;
B1 — IA;
B2 — IB;
B3 — IC.

14.1.1.4 In addition to complying with the requirements of 14.1.1.2, ships with ice notation B are to be designed to ensure supply of cooling water when navigating in ice. For this purpose, at least one cooling water inlet chest is to be so arranged as to prevent its grating and sea suction from being blocked by brash ice.

14.1.1.5 In addition to the plans and documents required in other Chapters of this PART, for ships with ice notations B1*, B1, B2 and B3, main engine output calculations (including necessary diagrams) are to be submitted for approval.

14.1.2 *Main engine output*

14.1.2.1 The main engine output mentioned in this Chapter is the total maximum output the propulsion machinery can continuously deliver to propeller(s).

14.1.2.2 The main engine output is to be in no case less than 2,800 kW for Ice Class B1* and less than 1,000 kW for Ice Classes B1, B2 and B3.

14.1.2.3 For ships with ice notations B1*, B1, B2 and B3, the required main engine output N_r is to be determined by the following formula. The engine output requirement is to be calculated for two draughts. Draughts to be used are the maximum draught amidships referred to as UIWL and the minimum draught referred to as LIWL, as defined in 4.1.2 of PART TWO of the Rules. In the calculations, the ship's parameters which depend on the draught are to be determined at the appropriate draught, but *L* and *B* are to be determined only at the UIWL. The main engine output is not to be less than the greater of these two outputs.

$$N_r = K_e \frac{\left(\frac{R_{CH}}{1000}\right)^{3/2}}{D_p} \quad \text{kW}$$

where: D_p — diameter of the propeller, in m;

K_e — propulsion coefficient, for conventional propulsion systems, to be taken from Table 14.1.2.3(1), for advanced propulsion systems, to be determined by ship model tests and other equivalent methods, but the requirements of 14.1.2.4 are to be complied with.

Propulsion Coefficient K_e *Table 14.1.2.3(1)*

Propeller type or machinery	CP or electric or hydraulic propulsion machinery	FP propeller
1 propeller	2.03	2.26
2 propellers	1.44	1.60
3 propellers	1.18	1.31

R_{CH} — the resistance of the ship in a channel with brash ice and a consolidated layer, in N, to be determined by the following formula:

$$R_{CH} = C_1 + C_2 + 845 C_\mu \left(H_F + H_M\right)^2 \left(B + C_\psi H_F\right) + 42 L_{PAR} H_F^2 + 825 \left(\frac{LT}{B^2}\right)^3 \frac{A_{wf}}{L}$$

where C_1 and C_2 are coefficients taking into account a consolidated upper layer of the brash ice and taken as zero for B1, B2 and B3; for B1*:

$$C_1 = 23\frac{BL_{PAR}}{\frac{2T}{B}+1} + (1+0.021\varphi_1)(45.8B + 14.7L_{BOW} + 29BL_{BOW});$$

$$C_2 = (1+0.063\varphi_1)(1530+170B) + (400+480\frac{T}{B})\frac{B^2}{\sqrt{L}};$$

$$C_\mu = 0.15\cos\varphi_2 + \sin\psi\sin\alpha, \quad C_\mu \geq 0.45;$$

$$C_\psi = 0.047\psi - 2.115, \text{ and } C_\psi = 0 \text{ if } \psi \leq 45°;$$

$$\left(\frac{LT}{B^2}\right)^3 \text{ is not to be greater than 20 or less than 5;}$$

$$\psi = \arctan\left(\frac{\tan\varphi_2}{\sin\alpha}\right);$$

A_{wf} — area of waterline of the bow, in m^2, see Figure 14.1.2.3;

B — maximum breadth of the ship, measured horizontally from outside of frame to outside of frame, in m;

H_M — thickness of the brash ice in mid channel, in m, to be taken as 1.0 for B1* and B1, 0.8 for B2 and 0.6 for B3;

H_F — thickness of the brash ice layer displaced by the bow, in m, $H_F = 0.26 + \sqrt{H_M B}$;

L_{BOW} — length of the bow, in m, see Figure14.1.2.3;

L_{PAR} — length of the parallel midship body, in m, see Figure 14.1.2.3;

L — length of the ship between the perpendiculars, in m, measured from the forward side of the stem to the after side of the rudder post, or to the center of the rudder stock if there is no rudder post;

T — actual ice class draughts of the ship, i.e. maximum draught amidships referred to as UIWL and the minimum draught referred to as LIWL, in m;

α — the angle of the waterline at B/4, in °, see Figure 14.1.2.3;

φ_1 — the rake of the stem at the centerline, in °, see Figure 14.1.2.3, for bulbous bow, φ_1 = 90°;

φ_2 — the rake of the bow at B/4, in °, see Figure 14.1.2.3.

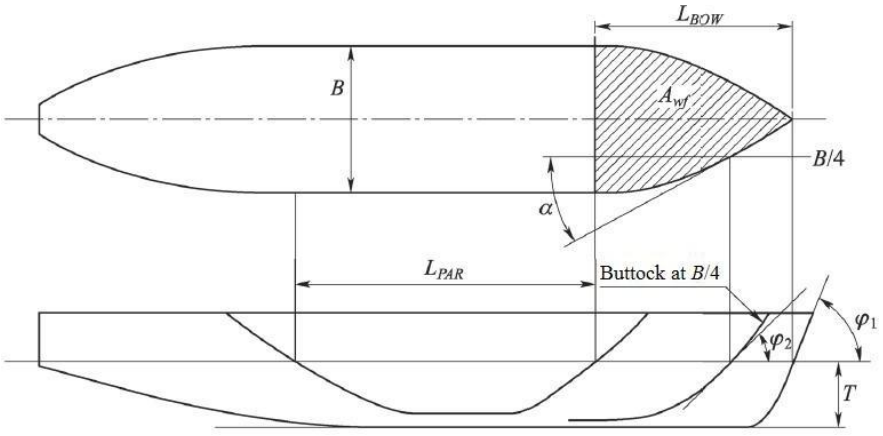

Figure 14.1.2.3

14.1.2.4 Where the value of K_e or R_{CH} is determined by ship model tests and other equivalent methods, the design requirement for ice classes is a minimum speed of 5 knots in the following brash ice channels:

B1* H_M = 1.0 m and a 0.1 m thick consolidated layer of ice;

B1 H_M = 1.0 m;

B2 H_M = 0.8 m;

B3 H_M = 0.6 m.

Section 2 PROPULSION MACHINERY

14.2.1 *General requirements*

14.2.1.1 These requirements apply to propulsion machinery, including controllable pitch (CP) or fixed pitch (FP) propellers and ducted-type propellers.The loads given are the expected ice loads for the ship's entire service life under normal operational conditions, including loads resulting from the changing rotational direction of fixed pitch propellers. However, these loads do not cover off-design operational conditions, for example when a stopped propeller is dragged through ice.

14.2.1.2 These requirements also apply to azimuthing and fixed thrusters for main propulsion, considering loads resulting from propeller-ice interaction and loads on the thruster body/ice interaction. The given loads are the expected ice loads for the ship's entire service life under normal operational conditions. However, the load models do not include propeller/ice interaction loads when ice enters the propeller of a turned azimuthing thruster from the side (radially). The local strength of the thruster body is to be sufficient to withstand local ice pressure when the thruster body is designed for extreme loads. The thruster global vibrations caused by blade order excitation on the propeller may cause significant vibratory loads.

14.2.1.3 The given loads are intended for component strength calculations only and are total loads including ice-induced loads and hydrodynamic loads during propeller/ice interaction. The presented maximum loads are based on a worst case scenario that occurs once during the service life of the ship. Thus, the load level for a higher number of loads is lower.

14.2.1.4 If the highest point of the propeller is not at a depth of at least h_0 as specified in Table 4.2.4.2(1), Chapter 4, PART TWO of the Rules below the water surface when the ship is in ballast condition, the propulsion system is to be designed according to ice class B1 for ice classes B2 and B3.

14.2.2 *Definitions of parameter symbols and loads*

14.2.2.1 The main symbols, designations and units used for parameters in this Section are defined as follows:

c — chord length, in m, of blade section;
$c_{0.7}$ — chord length, in m, of blade section at 0.7 R propeller radius;
D — propeller diameter, in m;
d — external diameter, in m, of propeller hub;
D_{limit} — limit value, in m, for propeller diameter;
EAR — expanded blade area ratio;
F_b — maximum backward blade force, in kN, for the ship's service life;
F_{ex} — ultimate blade load, in kN, resulting from blade loss through plastic bending, referred to as blade failure load for short;
F_f — maximum forward blade force, in kN, for the ship's service life;
F_{ice} — ice load, in kN;
$(F_{\text{ice}})_{\max}$ — maximum ice load, in kN, for the ship's service life;
h_0 — depth, in m, of the propeller centreline from lower ice waterline;
H_{ice} — thickness, in m, of maximum design ice block entering into propeller;
I — equivalent mass moment, in kgm^2, of inertia of all parts on engine side of component under consideration;
I_t — equivalent mass moment, in kgm^2, of inertia of the whole propulsion system;
k — shape parameter for Weibull distribution;
LIWL — lower ice waterline, in m;
m — slope for S-N curve in log/log scale;
M_{BL} — blade bending moment, in kN·m;
n — propeller rotational speed, in r/s;
n_n — nominal propeller rotational speed, in r/s, at maximum continuous rating (MCR) in free running condition;
N_{class} — reference number of impacts per propeller rotational speed per ice class;
N_{ice} — total number of ice loads on propeller blade for the ship's service life;
N_R — reference number of load for equivalent fatigue stress (10^8 cycles);
N_Q — number of propeller revolutions during a milling sequence;
$P_{0.7}$ — propeller pitch, in m, at 0.7 R radius;
$P_{0.7n}$ — propeller pitch, in m, at 0.7 R radius at MCR in free running condition;
$P_{0.7b}$ — propeller pitch, in m, at 0.7 R radius at MCR in bollard condition;
Q — torque, in kN·m;

Q_{emax} — maximum engine torque, in kN·m;
Q_{max} — maximum torque, in kN·m, on the propeller resulting from propeller-ice interaction;
Q_{max}^{n} — maximum torque, in kNm, on the propeller resulting from propeller/ice interaction reduced to the rotational speed in question;
Q_{motor} — electric motor peak torque, in kN·m;
Q_n — nominal torque, in kN·m, at MCR in free running condition;
Q_r — maximum response torque, in kN·m, along the propeller shaft line;
Q_{peak} — maximum of the response torque Q_r, in kNm;
Q_{smax} — maximum spindle torque, in kN·m, of the blade for the ship's service life;
Q_{sex} — maximum spindle torque due to blade failure caused by plastic bending F_{ex}, in kNm;
Q_{vib} — vibratory torque at considered component, taken from frequency domain open water torque vibration calculation (TVC) , in kNm;
R — propeller radius, in m;
r — blade section radius, in m;
T — propeller thrust, in kN;
T_b — maximum backward propeller ice thrust, in kN, for the ship's service life;
T_f — maximum forward propeller ice thrust, in kN, for the ship's service life;
T_n — propeller thrust, in kN, at MCR in free running condition;
T_r — maximum response thrust, in kN, along the shaft line;
t — maximum blade section thickness, in m;
Z — number of propeller blades;
α_i — duration of propeller blade/ice interaction expressed in rotation angle, in degrees;
a_1 — phase angle of propeller ice torque for blade order excitation component, in degrees;
a_2 — phase angle of propeller ice torque for twice the blade order excitation component, in degrees;
$\gamma_{\varepsilon 1}$ — the reduction factor for fatigue (scatter effect);
$\gamma_{\varepsilon 2}$ — the reduction factor for fatigue (test specimen size effect);
γ_v — the reduction factor for fatigue (variable amplitude loading effect);
γ_m — the reduction factor for fatigue (mean stress effect);
ρ — a reduction factor for fatigue correlating the maximum stress amplitude to the equivalent fatigue stress for 10^8 stress cycles;
$\sigma_{0.2}$ — proof yield strength, in MPa, of blade material;
σ_{exp} — mean fatigue strength, in MPa, of blade material at 10^8 cycles to failure in seawater;
σ_{fat} — equivalent fatigue ice load stress amplitude, in MPa, for 10^8 stress cycles;
σ_{fl} — characteristic fatigue strength, in MPa, for blade material;
σ_{ref} — reference stress, in MPa, $\sigma_{ref} = 0.6 \cdot \sigma_{0.2} + 0.4 \cdot \sigma_u$;
σ_{ref2} — reference stress, in MPa, $\sigma_{ref2} = 0.7 \cdot \sigma_u$ or $\sigma_{ref2} = 0.6 \cdot \sigma_{0.2} + 0.4 \cdot \sigma_u$, whichever is less;
σ_{st} — maximum stress, in MPa, resulting from F_b or F_f;
σ_u — ultimate tensile strength, in MPa, of blade material;
$(\sigma_{ice})_{bmax}$ — principal stress, in MPa, caused by the maximum backward propeller ice load;
$(\sigma_{ice})_{fmax}$ — principal stress, in MPa, caused by the maximum forward propeller ice load;
$(\sigma_{ice})_{max}$ — maximum ice load stress amplitude, in MPa.

14.2.2.2 The definitions and uses of loads used in these requirements are given in Table 14.2.2.2.

Definitions and Uses of Loads *Table 14.2.2.2*

Load	Definition	Use of the load in design process
F_b	The maximum lifetime backward force on a propeller blade resulting from propeller/ice interaction, including hydrodynamic loads on that blade. The direction of the force is perpendicular to 0.7 R chord line. See Figure 14.2.2.2. Ice contact pressure at the leading edge is shown with small arrows	Design force for strength calculation of the propeller blade
F_f	The maximum lifetime forward force on a propeller blade resulting from propeller/ice interaction, including hydrodynamic loads on that blade. The direction of the force is perpendicular to 0.7 R chord line	Design force for calculation of strength of the propeller blade.
Q_{smax}	The maximum lifetime spindle torque on a propeller blade resulting from propeller/ice interaction, including hydrodynamic loads on that blade	In designing the propeller strength, the spindle torque is taken into account because the propeller load is acting on the blade as distributed pressure on the leading edge or tip area

Load	Definition	Use of the load in design process
T_b	The maximum lifetime thrust on propeller (all blades) resulting from propeller/ice interaction. The direction of the thrust is the propeller shaft direction and the force is opposite to the hydrodynamic thrust	Used for estimation of the response thrust T_r. T_b can be used as an estimate of excitation for axial vibration calculations. However, axial vibration calculations are not required in these requirements
T_f	The maximum lifetime thrust on propeller (all blades) resulting from propeller/ice interaction. The direction of the thrust is the propeller shaft direction acting in the direction of hydrodynamic thrust	Used for estimation of the response thrust T_r. T_f can be used as an estimate of excitation for axial vibration calculations. However, axial vibration calculations are not required in these requirements
Q_{max}	The maximum ice-induced torque resulting from propeller/ice interaction on one propeller blade, including hydrodynamic loads on that blade	Used for estimation of the response torque (Q_r) along the propulsion shaft line and as excitation for torsional vibration calculations
F_{ex}	Ultimate blade load resulting from blade loss through plastic bending. The force may cause total failure of the blade so that plastic hinge is caused to the root area. The force is acting on 0.8 *R*. Spindle arm is to be taken as 2/3 of the distance between the axis of blade rotation and the leading/trailing edge (whichever is the greater) at the 0.8 *R* radius	Blade failure load is used to dimension the blade bolts, pitch control mechanism, propeller shaft, propeller shaft bearing and thrust bearing. The objective is to guarantee that total propeller blade failure should not cause damage to other components
Q_r	Maximum response torque along the propeller shaft line, taking into account the dynamic behavior of the shaft line for ice excitation (torsional vibration) and hydrodynamic mean torque on propeller	Design torque for propeller shaft line components
T_r	Maximum response thrust along shaft line, taking into account the dynamic behavior of the shaft line for ice excitation (axial vibration) and hydrodynamic mean thrust on propeller	Design thrust for propeller shaft line components
F_{ti}	Maximum response force caused by ice block impacts on the thruster body or the propeller hub	Design load for thruster body and slewing bearings
F_{tr}	Maximum response force on the thruster body caused by ice ridge/thruster body interaction.	Design load for thruster body and slewing bearings

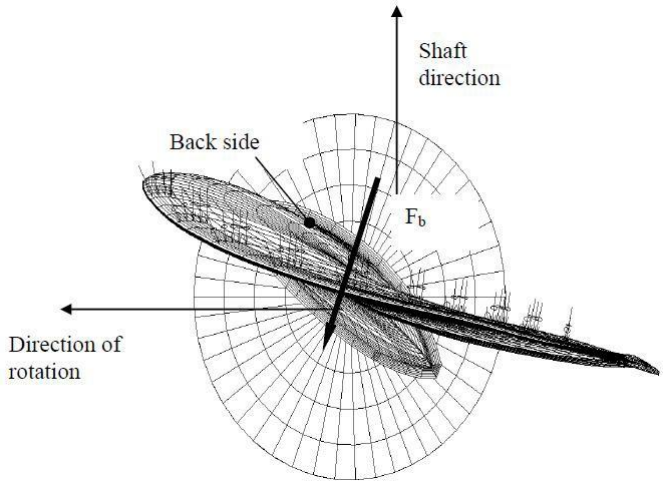

Figure 14.2.2.2 Direction of the backward blade force

14.2.3 Design ice conditions

14.2.3.1 In estimating the ice loads of the propeller for ice classes, different types of operation as given in Table 14.2.3.1 were taken into account.

Types of Operation for Ice Classes *Table 14.2.3.1*

Ice class	Operation of the ship
B1*	The ship may proceed by ramming for operation in ice channels and in level ice (not requiring ice breaker assistance)
B1, B2, B3	Operation in ice channels (if necessary, with ice breaker assistance)

14.2.3.2 For the estimation of design ice loads, a maximum ice block size is first to be determined. The maximum design ice block entering the propeller is a rectangular ice block with the dimensions $H_{ice} \times 2\ H_{ice} \times 3\ H_{ice}$. The design thickness of the ice block (H_{ice}) is given in Table 14.2.3.2.

Design Ice Thickness *Table 14.2.3.2*

Ice class	B1*	B1	B2	B3
Thickness of the design maximum ice block entering the propeller (H_{ice})	1.75 m	1.5 m	1.2 m	1.0 m

14.2.4 Materials

14.2.4.1 Materials exposed to seawater

Materials of components exposed to seawater, such as propeller blades, propeller hubs, and thruster body, are to have an elongation of not less than 15% on a test specimen, the gauge length of which is five times the diameter. A Charpy-V impact test is to be carried out for materials other than bronze and austenitic stainless steel. An average impact energy value of not less than 20 J taken from three tests is to be obtained at minus 10℃. For nodular cast iron, average impact energy of 10 J at minus 10 ℃ is required accordingly.

14.2.4.2 Materials exposed to seawater temperature

Materials exposed to seawater temperature are to be of ductile material. An average impact energy value of not less than 20 J taken from three tests is to be obtained at minus 10℃. This requirement applies to the propeller shaft, blade bolts, CP mechanisms, shaft bolts, strut-pod connecting bolts etc. This does not apply to surface hardened components, such as bearings and gear teeth. The nodular cast iron of a ferrite structure type may be used for relevant parts other than bolts. The average impact energy for nodular cast iron is to be a minimum of 10 J at minus 10 ℃.

14.2.5 *Design loads*

14.2.5.1 Design loads on propeller blades

F_b is the maximum force experienced during the lifetime of the ship that bends a propeller blade backwards when the propeller mills an ice block while rotating ahead. F_f is the maximum force experienced during the lifetime of the ship that bends a propeller blade forwards when the propeller mills an ice block while rotating ahead. These forces originate from different propeller/ice interaction phenomena, not acting simultaneously. Hence they are to be applied to one blade separately.

(1) Maximum backward blade force F_b for propellers

For $D \le D_{\text{limit}}$

$$F_b = 27(nD)^{0.7}\left(\frac{EAR}{Z}\right)^{0.3} D^2 \quad \text{kN}$$

For $D > D_{\text{limit}}$

$$F_b = 23(nD)^{0.7}\left(\frac{EAR}{Z}\right)^{0.3} DH_{ice}^{1.4} \quad \text{kN}$$

where: $D_{\text{limit}} = 0.85H_{ice}^{1.4}$, in m;

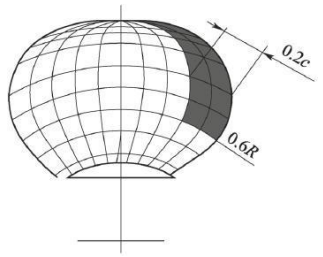
n — the nominal rotational speed (at MCR in free running condition) for a CP propeller and 85% of the nominal rotational speed (at MCR in free running condition) for an FP propeller.

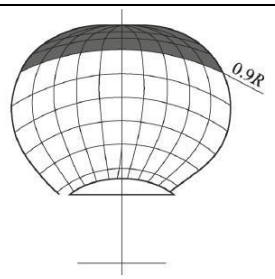
(2) Maximum forward blade force F_f for propellers

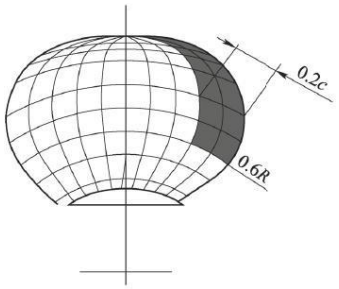
For $D \le D_{\text{limit}}$

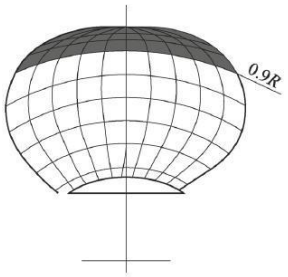
$$F_f = 250\frac{EAR}{Z}D^2 \quad \text{kN}$$

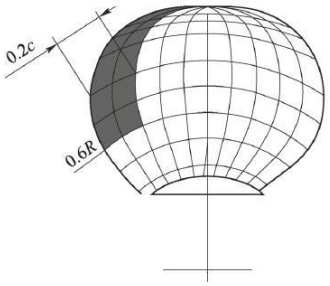
For $D > D_{\text{limit}}$











$$F_f = 500\frac{EAR}{Z}D\left(\frac{1}{1-\frac{d}{D}}\right)H_{ice} \quad \text{kN}$$

where: $D_{limit} = \left(\frac{2}{1-\frac{d}{D}}\right)H_{ice}$, in m.

(3) Loaded area on the blade for propellers

Load cases 1 ~ 4 are to be covered, as given in Table 14.2.5.1(3), for CP and FP propellers. In order to obtain blade ice loads for a reversing propeller, load case 5 is also to be covered for FP propellers.

Load Cases for Propellers *Table 14.2.5.1(3)*

Load case	Force	Loaded area	Right-handed propeller blade seen from behind
Load case 1	F_b	Uniform pressure applied on the back of the blade (suction side) to an area from 0.6 R to the tip and from the leading edge to 0.2 times the chord length	
Load case 2	50%F_b	Uniform pressure applied on the back of the blade (suction side) on the propeller tip area outside 0.9 R radius	
Load case 3	F_f	Uniform pressure applied on the blade face (pressure side) to an area from 0.6 R to the tip and from the leading edge to 0.2 times the chord length	
Load case 4	50%F_f	Uniform pressure applied on propeller face (pressure side) on the propeller tip area outside 0.9 R radius	
Load case 5	60%F_f or F_b, whichever is greater	Uniform pressure applied on propeller face (pressure side) to an area from 0.6 R to the tip and from the trailing edge to 0.2 times the chord length	

(4) Maximum backward blade ice force F_b for ducted propellers

For $D \leq D_{limit}$

$$F_b = 9.5(nD)^{0.7}\left(\frac{EAR}{Z}\right)^{0.3} D^2 \qquad \text{kN}$$

For $D > D_{limit}$

$$F_b = 66\,(nD)^{0.7}\left(\frac{EAR}{Z}\right)^{0.3} D^{0.6} H_{ice}^{1.4} \quad \text{kN}$$

where: $D_{limit} = 4\,H_{ice}$, in m;

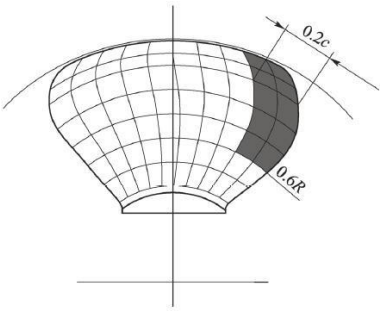
n — the nominal rotational speed (at MCR in free running condition) for a CP propeller and 85% of the nominal rotational speed (at MCR in free running condition) for an FP propeller.

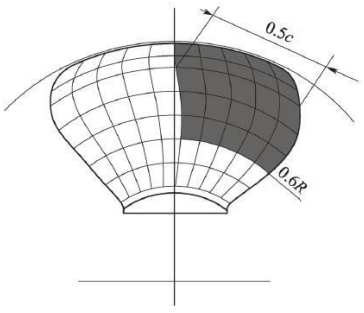
(5) Maximum forward blade ice force F_f for ducted propellers

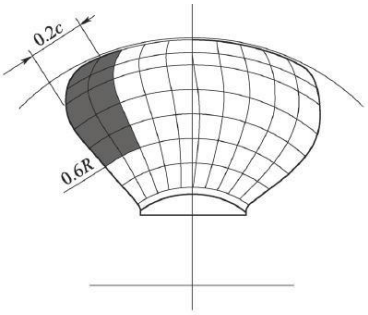
For $D \le D_{limit}$

$$F_f = 250\frac{EAR}{Z}D^2 \quad \text{kN}$$

For $D > D_{limit}$







$$F_f = 500\frac{EAR}{Z}D\left(\frac{1}{1-\frac{d}{D}}\right)H_{ice} \quad \text{kN}$$

where: $D_{limit} = \left(\frac{2}{1-\frac{d}{D}}\right)H_{ice}$, in m.

(6) Loaded area on the blade for ducted propellers

Load cases 1 and 3 are to be covered as given in Table 14.2.5.1(6) for all propellers, and load case 5 is to be additionally covered for an FP propeller to reflect ice loads when the propeller is reversed.

Load Cases for Ducted Propellers *Table 14.2.5.1(6)*

Load case	Force	Loaded area	Right-handed propeller blade seen from behind
Load case 1	F_b	Uniform pressure applied on the back of the blade (suction side) to an area from 0.6 R to the tip and from the leading edge to 0.2 times the chord length	
Load case 3	F_f	Uniform pressure applied on the blade face (pressure side) to an area from 0.6 R to the tip and from the leading edge to 0.2 times the chord length	
Load case 5	60%F_f or F_b, whichever is greater	Uniform pressure applied on propeller face (pressure side) to an area from 0.6 R to the tip and from the trailing edge to 0.2 times the chord length	

(7) Maximum blade spindle torque for open and ducted propellers

The spindle torque around the axis of the blade fitting is to be calculated both for the maximum backward blade force F_b and forward blade force F_f, which are applied as in Table 14.2.5.1(3) and Table 14.2.5.1(6). The larger of the obtained torques is used as the dimensioning torque. If the above method gives a value which is less than the

$$Q_{smax} = 0.25 F c_{0.7} \quad \text{kN·m}$$

default value given by the formula below, the default value is to be used.

where: F — F_b or F_f, whichever is greater.

(8) Load distributions for blade loads

The Weibull distribution (probability that F_{ice} exceeds $(F_{ice})_{max}$), as given in Figure 14.2.5.2(8), is used for the fatigue design of the blade.

$$P\left(\frac{F_{ice}}{(F_{ice})_{max}} \geq \frac{F}{(F_{ice})_{max}}\right) = e^{\left(-\left(\frac{F}{(F_{ice})_{max}}\right)^{k} \ln(N_{ice})\right)}$$

where: k — shape parameter of the spectrum, k = 0.75 for an open propeller and k = 1.0 for a ducted propeller;

N_{ice} — number of load cycles in the spectrum;

F_{ice} — random variable for ice loads on the blade, $0 \leq F_{ice} \leq (F_{ice})_{max}$.

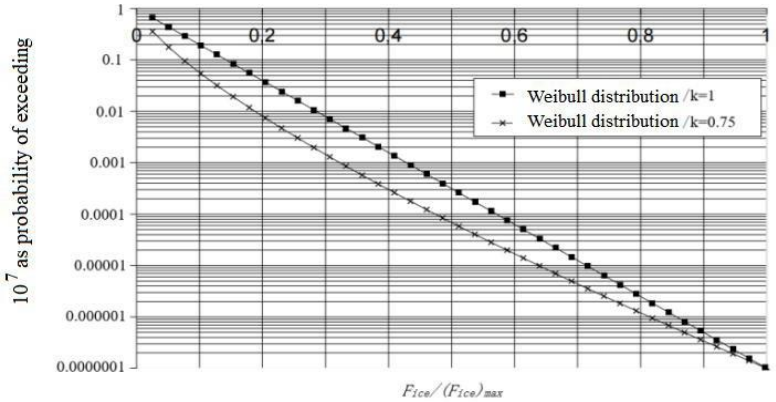


Figure 14.2.5.1(8) Weibull distribution (probability of exceeding) used for fatigue design

(9) Number of ice load cycles

The number of load cycles per propeller blade in the load spectrum is to be determined according to the following formula:

$$N_{ice} = k_1 k_2 k_3 N_{class} n_n$$

where: N_{class}— reference number of impacts per propeller rotational speed for ice classes, taken from Table 14.2.5.1(9);

k_1 — propeller location factor, k_1 = 1 for centre propellers bow first operation, k_1 = 2 for wing propellers bow first operation and k_1 = 3 for pulling propeller (wing and centre) bow propeller or stern first operation;

k_2 — submersion factor, determined as follows:

$k_4 = 0.8 - f$ for $f < 0$;

$k_4 = 0.8 - 0.4 f$ for $0 \leq f \leq 1$;

$k_4 = 0.6 - 0.2 f$ for $1 < f \leq 2.5$;

$k_4 = 0.1$ for $f > 2.5$;

where: $f = \frac{h_0 - H_{ice}}{D/2} - 1$

k_3 — propulsion machinery type factor, k_3 = 1 for fixed thrusters and k_3 = 1.2 for azimuthing thrusters;

Reference Number of Impacts per Propeller Rotational
Speed for Ice Classes **Table 14.2.5.1(9)**

Ice class	B1*	B1	B2	B3
Reference number of impacts (during the service life)	9×10^6	6×10^6	3.4×10^6	2.1×10^6

For components that are subject to loads resulting from propeller/ice interaction with all the propeller blades, the number of load cycles (N_{ice}) is to be multiplied by the number of propeller blades (Z).

14.2.5.2 Axial design loads for open and ducted propellers

(1) Maximum ice thrust T_f and T_b on propeller for open and ducted propellers

The maximum forward and backward ice thrusts are:

$$T_f = 1.1F_f \quad \text{kN}$$

$$T_b = 1.1F_b \quad \text{kN}$$

(2) Design thrust along the propulsion shaft line for open and ducted propellers

The design thrust along the propeller shaft line is to be calculated with the formulae below. The greater value of the forward and backward direction loads is to be taken as the design load for both directions. The factors 2.2 and 1.5 take into account the dynamic magnification resulting from axial vibration.

In a forward direction:

$$T_r = T + 2.2\ T_f \quad \text{kN}$$

In a backward direction:

$$T_r = 1.5\ T_b \quad \text{kN}$$

If the hydrodynamic bollard thrust, T, is unknown, T is to be taken from Table 14.2.5.2(2).

Value of T *Table 14.2.5.2(2)*

Propeller type	T
CP propellers (open)	$1.25\ T_n$
CP propellers (ducted)	$1.1\ T_n$
FP propellers driven by turbine or electric motor	T_n
FP propellers driven by diesel engine (open)	$0.85\ T_n$
FP propellers driven by diesel engine (ducted)	$0.75\ T_n$

Note: T_n is the nominal propeller thrust at MCR in free running open water condition.

14.2.5.3 Torsional design loads

(1) Design ice torque Q_{max} on propeller for open propellers (maximum value during the service life of the ship)

For $D \le D_{limit}$

$$Q_{max} = 10.9\left(1-\frac{d}{D}\right)\left(\frac{P_{0.7}}{D}\right)^{0.16}(nD)^{0.17}D^3 \quad \text{kN·m}$$

For $D > D_{limit}$

$$Q_{max} = 20.7\left(1-\frac{d}{D}\right)\left(\frac{P_{0.7}}{D}\right)^{0.16}(nD)^{0.17}D^{1.9}H_{ice}{}^{1.1} \quad \text{kN·m}$$

where: $D_{limit} = 1.8\ H_{ice}$;

n — rotational propeller speed at MCR, in r/s, in bollard condition. If unknown, n is to be taken from Table 14.2.5.3(1):

Value of n *Table 14.2.5.3(1)*

Propeller type	n
CP propellers (open)	n_n
FP propellers driven by turbine or electric motor	n_n
FP propellers driven by diesel engine (open)	$0.85\ n_n$

Note: n_n is the nominal rotational speed at MCR in free running open water condition.

For CP propellers, the propeller pitch $P_{0.7}$ is to correspond to MCR in bollard condition, i.e. taken as $P_{0.7b}$. If unknown, $P_{0.7}$ is to be taken as $0.7 \cdot P_{0.7n}$, where $P_{0.7n}$ is the propeller pitch at MCR in free running condition.

(2) Design ice torque Q_{max} on propeller for ducted propellers (maximum value during the service life of the ship)

For $D \le D_{limit}$

$$Q_{max} = 7.7\left(1-\frac{d}{D}\right)\left(\frac{P_{0.7}}{D}\right)^{0.16}(nD)^{0.17}D^3 \qquad \text{kN·m}$$

For $D > D_{limit}$

$$Q_{max} = 14.6\left(1-\frac{d}{D}\right)\left(\frac{P_{0.7}}{D}\right)^{0.16}(nD)^{0.17}D^{1.9}H_{ice}{}^{1.1} \qquad \text{kN·m}$$

where: $D_{limit} = 1.8\,H_{ice}$;

n — rotational propeller speed at MCR, in r/s, in bollard condition. If unknown, n is to be taken from Table 14.2.5.3(1).

For CP propellers, the propeller pitch $P_{0.7}$ is to correspond to MCR in bollard condition, i.e. taken as $P_{0.7b}$. If unknown, $P_{0.7}$ is to be taken as $0.7 \cdot P_{0.7n}$, where $P_{0.7n}$ is the propeller pitch at MCR in free running condition.

(3) Design torque for non-resonant shaft lines

If there is no bladed secondary torsional resonance within a speed range of 20% above or below the maximum operating speed under bollard conditions (i.e., the nominal speed n_n at maximum sustained power free running without ice) and within the usual speed range, the maximum response torque estimated by the equation below can be used.

Directly coupled two stroke diesel engines without flexible coupling

$$Q_{peak} = Q_{e\max} + Q_{vib} + Q_{\max}\frac{I_e}{I_t} \qquad \text{kNm}$$

and other plants

$$Q_{peak} = Q_{e\max} + Q_{\max}\frac{I_e}{I_t} \qquad \text{kNm}$$

where all the torques and the inertia moments are to be converted to equivalent values at the rotation speed of the component being examined.

If the maximum torque Q_{emax} is unknown, it is to be taken from Table 14.2.5.3(3):

Value of Q_{emax} *Table 14.2.5.3(3)*

Propeller type	Q_{emax}
Propellers driven by electric motor	Q_{motor}
CP propellers not driven by electric motor	Q_n
FP propellers driven by turbine	Q_n
FP propellers driven by diesel engine	$0.75Q_n$

Note: Q_{motor} is the electric motor peak torque.

(4) Design torque for shaft lines having resonances

If there is bladed secondary torsional resonance within a speed range of 20% above or below the maximum operating speed under bollard conditions (i.e., the nominal speed n_n at maximum sustained power free running without ice) and within the usual speed range, the design torque (Q_{peak}) of the shaft component is to be determined by means of torsional vibration analysis of the propulsion line. There are two alternative ways of performing the dynamic analysis.

1. Time domain calculation for estimated milling sequence excitation
2. Frequency domain calculation for blade orders sinusoidal excitation.

The frequency domain analysis is generally considered conservative compared to the time domain simulation, provided that there is a first blade order resonance in the considered speed range.

① Time domain calculation of torsional response

Time domain calculations are to be calculated for the MCR condition, MCR bollard conditions and for blade order resonant rotational speeds so that the resonant vibration responses can be obtained.

The load sequence given in this chapter, for a case where a propeller is milling an ice block, is to be used for the strength evaluation of the propulsion line. The given load sequence is not intended for propulsion system stalling analyses.

The following load cases are intended to reflect the operational loads on the propulsion system, when the propeller interacts with ice, and the respective reaction of the complete system. The ice impact and system response causes loads in the individual shaft line components. The ice torque Q_{max} may be taken as a constant value in the complete speed range. When considerations at specific shaft speeds are performed, a relevant Q_{max} may be calculated using the relevant speed according to 14.2.5.3.

Diesel engine plants without an elastic coupling are to be calculated at the least favourable phase angle for ice versus engine excitation, when calculated in the time domain. The engine firing pulses are to be included in the calculations and their standard steady state harmonics can be used.
If there is a blade order resonance just above the MCR speed, calculations are to cover rotational speeds up to 105% of the MCR speed.
The propeller ice torque excitation for shaft line transient dynamic analysis is to be defined as a sequence of blade impacts which are of a half sine shape.The torque resulting from a single blade ice impact as a function of the propeller rotation angle is as follows:
For For $\varphi = 0 \ldots \alpha_i$

$$Q(\varphi) = C_q Q_{max} \sin\left[\varphi\left(180/\alpha_i\right)\right] \quad \text{kN·m}$$

$\varphi = \alpha_i \ldots\ldots 360$

$$Q(\varphi) = 0 \quad \text{kN·m}$$

Where φ is the rotation angle from when the first impact occurs; α_i is the duration of propeller blade/ice interaction expressed in terms of the propeller rotation angle (see Figure 14.2.5.3(4)①-1); the parameters C_q and α_i are given in Table 14.2.5.3(4)①.

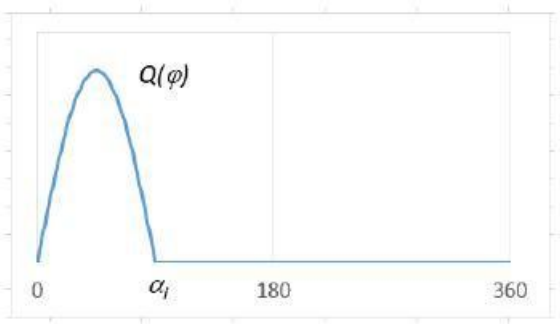

Figure 14.2.5.3(4)①-1 Schematic ice torque due to a single blade ice impact as a function of the propeller rotation angle

Values of Ice Impact Magnification Factor C_q **and Duration Factor α_i** **Table 14.2.5.3(4)①**

Torque excitation	Propeller/ice interaction	C_q	α_i(°)			
			Z=3	Z=4	Z=5	Z=6
Case 1	Single ice block	0.75	90	90	72	60
Case 2	Single ice block	1.0	135	135	135	135
Case 3	Two ice blocks (phase shift 360°/2/Z)	0.5	45	45	36	30
Case 4	Single ice block	0.5	45	45	36	30

The total ice torque is obtained by summing the torque of single blades, taking into account the phase shift 360°/Z, see Figure 14.2.5.3(4)①-2. In addition, at the beginning and at the end of the milling sequence a linear ramp function is to be used to increase C_q to its maximum value within one propeller revolution and vice versa to decrease it to zero (see the examples of different Z numbers in Figure 14.2.5.3(4)①-2).
The number of propeller revolutions during a milling sequence may be obtained as follows:

$$N_Q = 2H_{ice}$$

The number of impacts for blade order excitation is:

$$Z\ N_Q$$

An illustration of all excitation cases for different numbers of blades is given in Figure 14.2.5.3(4)①-2.
A dynamic simulation is to be performed for all excitation cases at the operational rotational speed range. For a fixed pitch propeller propulsion plant, a dynamic simulation is also to cover the bollard pull condition with a corresponding rotational speed assuming the maximum possible output of the engine.
If a speed drop occurs until the main engine is at a standstill, this indicates that the engine may not be sufficiently powered for the intended service task. For the consideration of loads, the maximum occurring torque during the speed drop process is to be used.

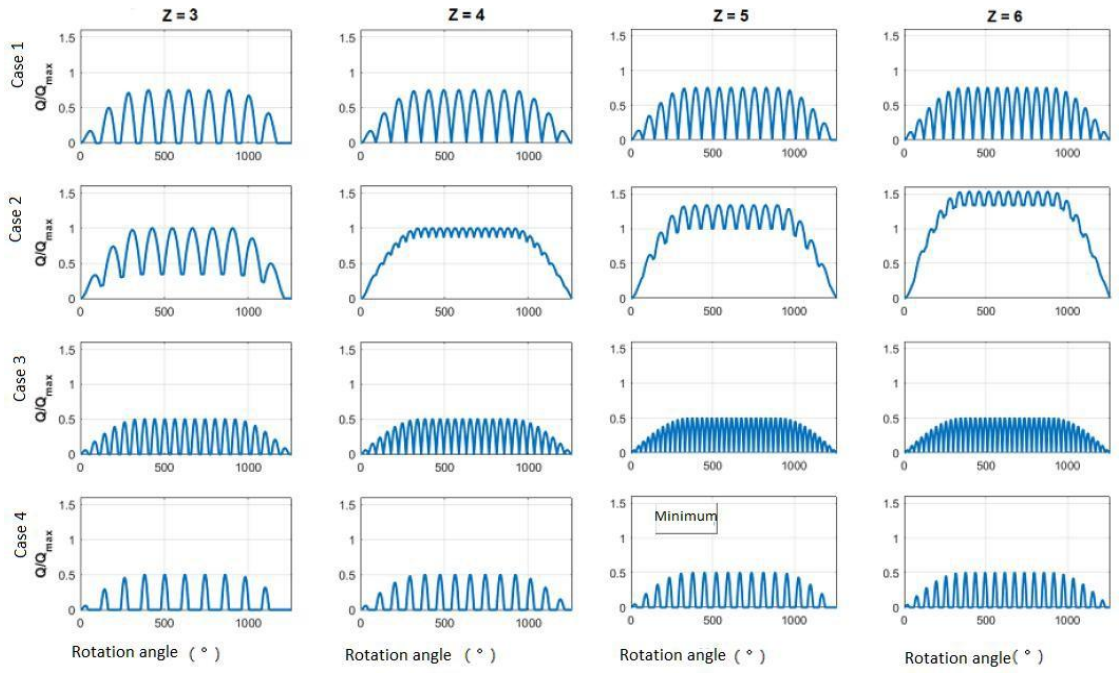

Figure 14.2.5.3(4)①-2 –The shape of the propeller ice torque excitation sequences for propellers with 3, 4, 5 or 6 blades

For the time domain calculation, the simulated response torque typically includes the engine mean torque and the propeller mean torque. If this is not the case, the response torques are to be obtained using the formula:

$$Q_{peak} = Q_{e\max} + Q_{rtd} \qquad \text{kNm}$$

where: Q_{rtd} is the maximum simulated torque obtained from the time domain analysis.

② Frequency domain calculation of torsional response

For frequency domain calculations, blade order and twice-the-blade-order excitation may be used. The amplitudes for the blade order and twice-the-blade-order sinusoidal excitation have been derived based on the assumption that the time domain half sine impact sequences were continuous, and the Fourier series components for blade order and twice-the-blade-order components have been derived. The propeller ice torque is then:

where: φ — rotation angle;

$$Q_F(\varphi) = Q_{\max} \cdot \left[C_{q0} + C_{q1} \cdot \sin\left(Z \cdot E_0 \cdot \varphi + \alpha_1\right) + C_{q2} \cdot \sin\left(2Z \cdot E_0 \cdot \varphi + \alpha_2\right) \right] \qquad \text{kNm}$$

α_1, α_2— phase angles of the excitation component;

C_{q0}—mean torque parameter;

C_{q1}—the first blade order excitation parameter;

C_{q2}—the second blade order excitation parameter;

E_0—the number of ice blocks in contact.

The values of the parameters for frequency domain excitation calculation are given in Table 14.2.5.3(4)②.

Coefficient values for frequency domain excitation calculation **Table 14.2.5.3(4)②**

Torque excitation	Z=3					
	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.375	0.375	-90	0	0	1
Excitation case 2	0.7	0.33	-90	0.05	-45	1
Excitation case 3	0.25	0.25	-90	0	0	2
Excitation case 4	0.2	0.25	0	0.05	-90	1
Torque excitation	Z=4					
	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.45	0.36	-90	0.06	-90	1
Excitation case 2	0.9375	0	-90	0.0625	-90	1
Excitation case 3	0.25	0.25	-90	0	0	2
Excitation case 4	0.2	0.25	0	0.05	-90	1
Torque excitation	Z=5					

	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.45	0.36	-90	0.06	-90	1
Excitation case 2	1.19	0.17	-90	0.02	-90	1
Excitation case 3	0.3	0.25	-90	0.048	-90	2
Excitation case 4	0.2	0.25	0	0.05	-90	1
Torque excitation	Z=6					
	C_{q0}	C_{q1}	α_1	C_{q2}	α_2	E_0
Excitation case 1	0.45	0.375	-90	0.05	-90	1
Excitation case 2	1.435	0.1	-90	0	0	1
Excitation case 3	0.3	0.25	-90	0.048	-90	2
Excitation case 4	0.2	0.25	0	0.05	-90	1

The design torque for the frequency domain excitation case is to be obtained using the formula:

$$Q_{peak} = Q_{\max} + Q_{vib} + \left(Q_{\max}^{n} C_{q0}\right) I_e / I_t + Q_{rf1} + Q_{rf2} \qquad \text{kNm}$$

where: Q_{max}^{n} — the maximum propeller ice torque at the operation speed in consideration;

C_{q0} — mean torque parameter, see Table 14.2.5.3(4)②;

Q_{rf1} — the blade order torsional response from the frequency domain analysis;

Q_{rf2} — the second order blade torsional response from the frequency domain analysis.

If the prime mover maximum torque, Q_{emax}, is not known, it is to be taken as given in Table 14.2.5.3(3). All the torque values have to be scaled to the shaft revolutions for the component in question.

③ Guidance for torsional vibration calculation

The aim of time domain torsional vibration simulations is to estimate the extreme torsional load for the ship's lifespan. The simulation model can be taken from the normal lumped mass elastic torsional vibration model, including damping. For a time domain analysis, the model should include the ice excitation at the propeller, other relevant excitations and the mean torques provided by the prime mover and hydrodynamic mean torque in the propeller. The calculations should cover variation of phase between the ice excitation and prime mover excitation. This is extremely relevant to propulsion lines with directly driven combustion engines. Time domain calculations are to be calculated for the MCR condition, MCR bollard conditions and for resonant speed, so that the resonant vibration responses can be obtained.

For frequency domain calculations, the load should be estimated as a Fourier component analysis of the continuous sequence of half sine load sequences. First and second order blade components should be used for excitation. The calculation should cover the entire relevant rpm range and the simulation of responses at torsional vibration resonances.

14.2.5.4 Blade failure load

(1) Bending force, F_{ex}

The ultimate load resulting from blade failure as a result of plastic bending around the blade root is to be calculated with the formula below, or alternatively by means of an appropriate stress analysis, reflecting the non-linear plastic material behaviour of the actual blade. In such a case, the blade failure area may be outside the root section. The ultimate load is assumed to be acting on the blade at the 0.8 R radius in the weakest direction of the blade. A blade is regarded as having failed if the tip is bent into an offset position by more than 10% of propeller diameter D.

$$F_{ex} = \frac{0.3ct^2\sigma_{refl}}{0.8D - 2r} \times 10^3 \qquad \text{kN}$$

where: $\sigma_{refl} = 0.6\sigma_{0.2} + 0.4\sigma_u$;

c, t and r are respectively the chord length, maximum thickness, and radius of the cylindrical root section of the blade at the weakest section outside the root fillet.

(2) Spindle torque, Q_{sex}

The maximum spindle torque due to a blade failure load acting at 0.8R is to be determined.

The force that causes blade failure typically reduces when moving from the propeller centre towards the leading and trailing edges. At a certain distance from the blade centre of rotation, the maximum spindle torque will occur. This maximum spindle torque is to be defined by an appropriate stress analysis or using the equation given below.

$$Q_{sex} = \max(C_{LE\,0.8}, 0.8C_{TE\,0.8})C_{spex}F_{ex}$$

where: $C_{spex} = C_{sp}C_{fex} = 0.7\left[1-\left(4\frac{EAR}{Z}\right)^3\right]$;

C_{sp} — a non-dimensional parameter taking account of the spindle arm;

C_{fex} —a non-dimensional parameter taking account of the reduction of the blade failure force at the location of the maximum spindle torque;

C_{spex} —If C_{spex} is below 0.3, a value of 0.3 is to be used for C_{spex};

$C_{LE0.8}$ —the leading edge portion of the chord length at 0.8R;

$C_{TE0.8}$ —the trailing edge portion of the chord length at 0.8R.

Figure 14.2.5.4(2) illustrates the spindle torque values due to blade failure loads across the entire chord length.

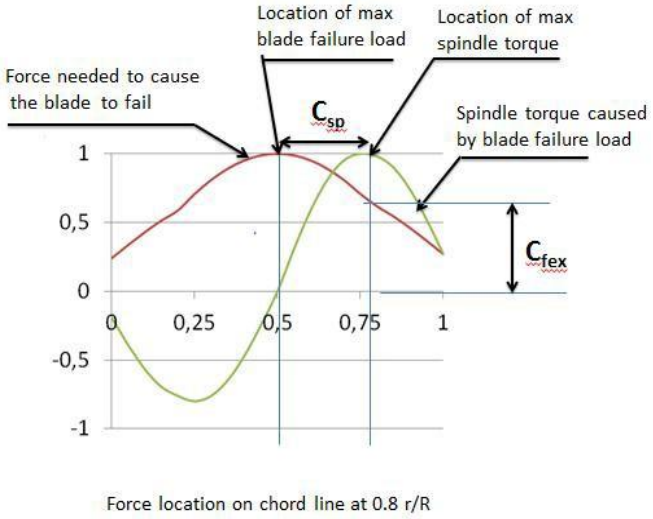

Figure 14.2.5.4(2)Schematic figure showing a blade failure load and the related spindle torque when the force acts at a different location on the chord line at radius 0.8R

14.2.6 Design

14.2.6.1 Design principle

The strength of the propulsion line is to be designed according to the pyramid strength principle. This means that the loss of the propeller blade is not to cause any significant damage to other propeller shaft line components.

14.2.6.2 Propeller blade

(1) Calculation of blade stresses

The blade stresses are to be calculated for the design loads given in paragraph 14.2.5.1. Finite element analysis is to be used for stress analysis of all propellers. The following simplified formulae can be used in estimating the blade stresses for all propellers at the root area (r/R < 0.5). The root area dimensions can be accepted even if the finite element analysis would show greater stresses at the root area.

$$\sigma_{st} = A_1 \frac{M_{BL}}{100 \times ct^2} \quad \text{MPa}$$

where the constant A_1 is the ratio of the actual stress to the stress obtained with beam equation. If the actual value is not available, A_1 is to be taken as 1.6. $M_{BL} = (0.75 - r/R)RF$ for the relative radius r/R < 0.5, where F is F_b or F_f, whichever is greater.

(2) Acceptability criterion

The following criterion for calculated blade stresses is to be fulfilled:

$$\frac{\sigma_{ref2}}{\sigma_{st}} \geq 1.3$$

where: σ_{st} — calculated stress for the design loads. If finite element analysis is used in estimating the stresses, equivalent von Mises stresses are to be used;

σ_{ref2} — reference stress, taken as the lesser of $0.7\sigma_u$ and $(0.6\sigma_{0.2} + 0.4\sigma_u)$.

(3) Fatigue design of propeller blade

The fatigue design of the propeller blade is based on an estimated load distribution for the service life of the ship and the S-N curve for the blade material. An equivalent stress that produces the same fatigue damage as the expected load distribution is to be calculated and the acceptability criterion for fatigue should be fulfilled as given in this paragraph. The equivalent stress cycles are specified as 1×10^8.

For materials with a two-slope SN curve (see Figure 14.2.6.2(3)-1), if the following criterion is fulfilled, fatigue calculations according to this Chapter are not required:

$$\sigma_{\exp} \geq B_1 \cdot \sigma_{ref2}{}^{B_2} \cdot \log(N_{ice})^{B_3}$$

where coefficients B_1, B_2 and B_3 for open and ducted propellers are given in the Table 14.2.6.2(3).

Values of B_1, B_2 and B_3 *Table 14.2.6.2(3)*

Coefficient	Open propeller	Ducted propeller
B_1	0.00328	0.00223
B_2	1.0076	1.0071
B_3	2.101	2.471

Two types of S-N curves are available for calculation of equivalent stresses. The two-slope S-N curve (slopes 4.5 and 10) is shown in Figure 14.2.6.2(3)-1 and the one-slope S-N curve (the slope can be chosen) in Figure 14.2.6.2(3)-2.

The type of the S-N curve is to be selected to correspond to the material properties of the blade. If the S-N curve is unknown, the two-slope S-N curve is to be used.

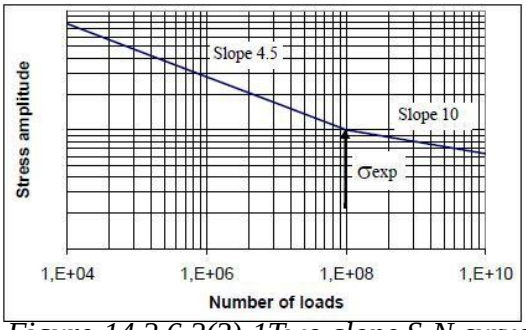

Figure 14.2.6.2(3)-1Two-slope S-N curve

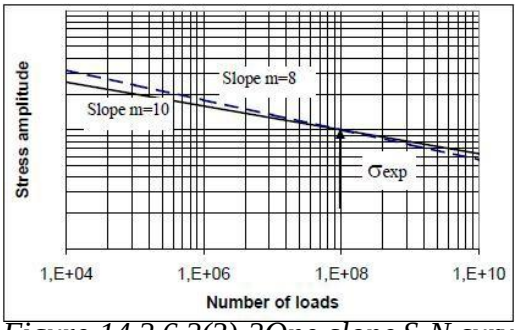

Figure 14.2.6.2(3)-2One-slope S-N curve

① Equivalent fatigue stress

The equivalent fatigue stress for 10^8 stress cycles which produces the same fatigue damage as the load distribution for the service life of the ship is:

$$\sigma_{fat} = \rho \cdot (\sigma_{ice})_{\max} \quad \text{MPa}$$

where: $(\sigma_{ice})_{\max}$ — mean value of the principal stress amplitudes resulting from design forward and backward blade forces at the location being studied, determined as follows:

$$(\sigma_{ice})_{\max} = 0.5 \cdot \left((\sigma_{ice})_{f\max} - (\sigma_{ice})_{b\max}\right) \quad \text{MPa}$$

where $(\sigma_{ice})_{f\max}$ is the principal stress resulting from forward load and $(\sigma_{ice})_{b\max}$ the principal stress resulting from backward load.

In calculation of $(\sigma_{ice})_{\max}$, case 1 and case 3 (or case 2 and case 4) are considered as a pair for $(\sigma_{ice})_{f\max}$, and $(\sigma_{ice})_{b\max}$ calculations. Case 5 is excluded from the fatigue analysis.

② Calculation of ρ parameter for two-slope S-N curve

The parameter ρ relates the maximum ice load to the distribution of ice loads according to the regression formulae.

$$\rho = C_1 \cdot (\sigma_{ice})_{\max}{}^{C_2} \cdot \sigma_{fl}{}^{C_3} \cdot \log(N_{ice})^{C_4}$$

where: $\sigma_{fl} = \gamma_{\varepsilon 1} \cdot \gamma_{\varepsilon 2} \cdot \gamma_v \cdot \gamma_m \cdot \sigma_{\exp}$

where $\gamma_{\varepsilon 1}$ and $\gamma_{\varepsilon 2}$ are respectively the reduction factor for scatter and test specimen size effect, γ_v the reduction factor for variable amplitude loading, and γ_m the reduction factor for mean stress, and $\gamma_\varepsilon = \gamma_{\varepsilon 1} \cdot \gamma_{\varepsilon 2} = 0.67$, $\gamma_v = 0.75$, and $\gamma_m = 0.75$ if actual values are not available; $\sigma_{\exp}$ is the mean fatigue strength of the blade material at 10^8 cycles to failure in seawater.

The values of coefficients C_1, C_2, C_3 and C_4 are given in Table 14.2.6.2(3)②.

Values of C_1, C_2, C_3 and C_4 **Table 14.2.6.2(3)②**

Coefficient	Open propeller	Ducted propeller
C_1	0.000747	0.000534
C_2	0.0645	0.0533
C_3	-0.0565	-0.0459
C_4	2.22	2.584

③ Calculation of ρ parameter for one-slope S-N curve

For materials with a one-slope S-N curve, as shown in Figure 14.2.6.2(3)-2, the ρ factor is to be calculated as follows:

$$\rho = \left(G \frac{N_{ice}}{N_R} \right)^{1/m} (\ln(N_{ice}))^{-1/k}$$

where: k — shape parameter of the Weibull distribution, k = 1.0 for ducted propellers and k = 0.75 for open propellers;

N_R — reference number of load cycles, taken as10^8;

N_{ice} —range is $5\times10^6 \le N_{ice} \le 10^8$;

G — Values for the G parameter are given in Table 14.2.6.2(3)③; linear interpolation may be used to calculate the G value for other m/k ratios than given in the Table.

Values of the Parameter G for Different m/k Ratios **Table 14.2.6.2(3)③**

m/k	G	m/k	G	m/k	G	m/k	G
3	6	5.5	287.9	8	40320	10.5	11.899E6
3.5	11.6	6	720	8.5	119292	11	39.917E6
4	24	6.5	1871	9	362880	11.5	136.843E6
4.5	52.3	7	5040	9.5	1.133E6	12	479.002E6
5	120	7.5	14034	10	3.623E6		

④ Acceptability criterion for fatigue

The equivalent fatigue stress at all locations on the blade is to fulfill the following acceptability criterion:

$$\frac{\sigma_{fl}}{\sigma_{fat}} \ge 1.5$$

where: σ_{fl} — characteristic fatigue strength of the blade material, in MPa, calculated as in 14.2.6.2(3)②;

σ_{fat}— equivalent fatigue ice load stress amplitude, in MPa, for 10^8 stress cycles.

14.2.6.3 Propeller bossing and CP mechanism

The blade bolts, the CP mechanism, the propeller boss, and the fitting of the propeller to the propeller shaft are to be designed to withstand the maximum and fatigue design loads, as defined in paragraph 14.2.5. The safety factor against yielding is to be greater than 1.3 and that against fatigue greater than 1.5. In addition, the safety factor for loads resulting from loss of the propeller blade through plastic bending, as defined in paragraph 14.2.5.4, is to be greater than 1.0 against yielding.

14.2.6.4 Propulsion shaft line

The shafts and shafting components, such as the thrust and stern tube bearings, couplings, flanges and sealings, are to be designed to withstand the propeller/ice interaction loads as given in paragraph 14.2.5. The safety factor is to be at least 1.3 against yielding for extreme operational loads, 1.5 for fatigue loads and 1.0 against yielding for the blade failure load.

(1) Shafts and shafting components

The ultimate load resulting from total blade failure, as defined in paragraph 14.2.5.4, should not cause yielding in shafts and shaft components. The loading is to consist of the combined axial, bending, and torsion loads. The minimum safety factor against yielding is to be 1.0 for bending and torsional stresses.

14.2.6.5 Azimuthing main propulsors

(1) Design principle

In addition to the above requirements for propeller blade dimensioning, azimuthing thrusters are to be designed for thruster body/ice interaction loads. Load formulae are given for estimating once in a lifetime extreme loads on the thruster body, based on the estimated ice condition and ship operational parameters. Two main ice load scenarios have been selected for defining the extreme ice loads. Examples of loads are illustrated in Figure 14.2.6.5(1). In addition, blade order thruster body vibration responses may be estimated for propeller excitation. The following load scenario types are considered:

① Ice block impact on the thruster body or propeller hub;
② Thruster penetration into an ice ridge that has a thick consolidated layer;
③ Vibratory response of the thruster at blade order frequency.

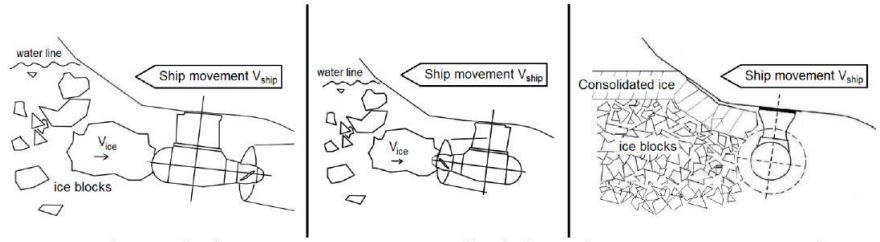

Figure 14.2.6.5(1) Examples of load scenario types

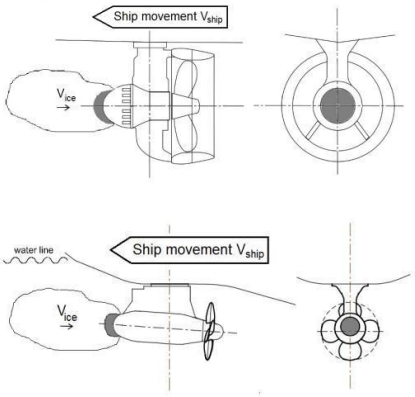
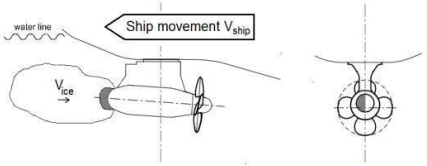
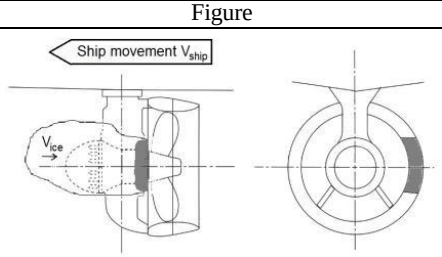
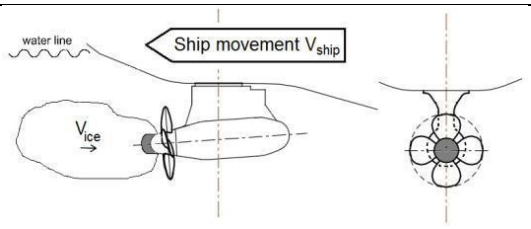
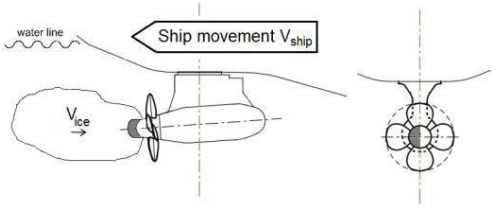


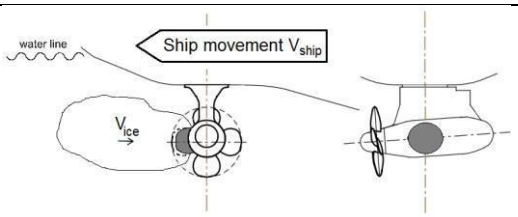


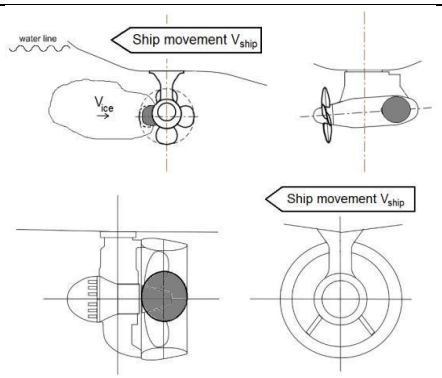
The steering mechanism, the fitting of the unit, and the body of the thruster are to be designed to withstand the plastic bending of a blade without damage. The loss of a blade is to be taken into account for the propeller blade orientation causing the maximum load on the component being studied. Top-down blade orientation typically places the maximum bending loads on the thruster body.











(2) Extreme ice impact loads

When the ship is operated in ice conditions, ice blocks formed in channel side walls or from the ridge consolidated layer may impact on the thruster body and the propeller hub. Exposure to ice impact is very much dependent on the ship size and ship hull design, as well as the location of the thruster. The contact force will grow in terms of thruster/ice contact until the ice block reaches the ship speed.

The thruster is to withstand the loads occurring when the design ice block defined in Table 14.2.3.2 impacts on the thruster body when the ship is sailing at a typical ice operating speed. Load cases for impact loads are given in Table 14.2.6.5(2)-1. The contact geometry is estimated to be hemi-spherical in shape. If the actual contact geometry differs from the shape of the hemisphere, a sphere radius is to be estimated so that the growth of the contact area as a function of penetration of ice corresponds as closely as possible to the actual geometrical shape penetration.

Load cases for azimuthing thruster ice impact loads *Table 14.2.6.5(2)-1*

Load case	Force	Loaded area	Figure
Load case T1a Symmetric longitudinal ice impact on thruster	F_{ti}	Uniform distributed load or uniform pressure, which are applied symmetrically on the impact area	
Load case T1b Non-symmetric longitudinal ice impact on thruster	50% of F_{ti}	Uniform distributed load or uniform pressure, which are applied on the other half of the impact area	

Load case	Force	Loaded area	Figure
Load case T1c Non-symmetric longitudinal ice impact on nozzle	F_{ti}	Uniform distributed load or uniform pressure, which are applied on the impact area. Contact area is equal to the nozzle thickness (H_{nz})*the contact height (H_{ice})	
Load case T2a Symmetric longitudinal ice impact on propeller hub	F_{ti}	Uniform distributed load or uniform pressure, which are applied symmetrically on the impact area	
Load case T2b Non-symmetric longitudinal ice impact on propeller hub	50% of F_{ti}	Uniform distributed load or uniform pressure, which are applied on the other half of the impact area	
Load case T3a Symmetric lateral ice impact on thruster body	F_{ti}	Uniform distributed load or uniform pressure, which are applied symmetrically on the impact area	
Load case T3b Non-symmetric lateral ice impact on thruster body or nozzle	F_{ti}	Uniform distributed load or uniform pressure, which are applied on the impact area. Nozzle contact radius R to be taken from the nozzle length (L_{nz})	

The ice impact contact load is to be calculated using the formula below. The related parameter values are given in Table 14.2.6.5(2)-2. The design operation speed in ice can be derived from Tables 14.2.6.5(2)-3 and 14.2.6.5(2)-4, or the ship in question's actual design operation speed in ice can be used. The longitudinal impact speed in Tables 14.2.6.5(2)-3 and 14.2.6.5(2)-4 refers to the impact in the thruster's main operational direction. For the pulling propeller configuration, the longitudinal impact speed is used for load case T2, impact on hub; and for the pushing propeller unit, the longitudinal impact speed is used for load case T1, impact on thruster end cap. For the opposite direction, the impact speed for transversal impact is applied.

$$F_{ti} = 34.5 C_{DMI} R_c^{0.5} \left(m_{ice} v_s^2 \right)^{0.333} \text{kN}$$

where: R_C —impacting part sphere radius, see Figure 14.2.6.5(2), in m;
m_{ice} —ice block mass, in kg;
V_s —ship speed at the time of contact, in m/s;
C_{DM1}—dynamic magnification factor for impact loads.

C_{DM1} is to be taken from Table 14.2.6.5(2)-2 if unknown.

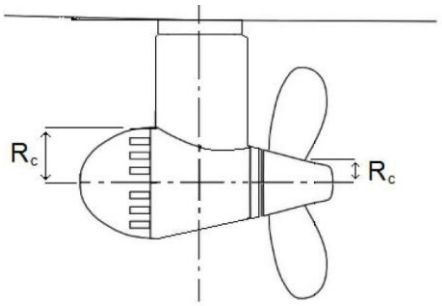


Figure 14.2.6.5(2) Dimensions used for R_c

For impacts on non-hemispherical areas, such as the impact on the nozzle, the equivalent impact sphere radius is to be estimated using the equation below.

$$R_{ceq} = \sqrt{\frac{A}{\pi}} \text{ m}$$

If the $2R_{ceq}$ is greater than the ice block thickness, the radius is set to half of the ice block thickness. For the impact on the thruster side, the pod body diameter can be used as a basis for determining the radius. For the impact on the propeller hub, the hub diameter can be used as a basis for the radius.

Parameter values for ice dimensions and dynamic magnification **Table 14.2.6.5(2)-2**

Ice class	B1*	B1	B2	B3
Thickness of the design ice block impacting thruster (2/3 of H_{ice}) (m)	1.17	1.0	0.8	0.67
Extreme ice block mass (m_{ice}) (kg)	8670	5460	2800	1600
C_{DMI} (if not known)	1.3	1.2	1.1	1

Impact speeds for aft centerline thruster **Table 14.2.6.5(2)-3**

Ice class	B1*	B1	B2	B3
Longitudinal impact in main operational direction (m/s)	6	5	5	5
Longitudinal impact in reversing direction (pushing unit propeller hub or pulling unit cover end cap impact) (m/s)	4	3	3	3
Transversal impact in bow first operation (m/s)	3	2	2	2
Transversal impact in stern first operation (double acting ship) (m/s)	4	3	3	3

Impact speeds for aft wing, bow centerline and bow wing thrusters **Table 14.2.6.5(2)-4**

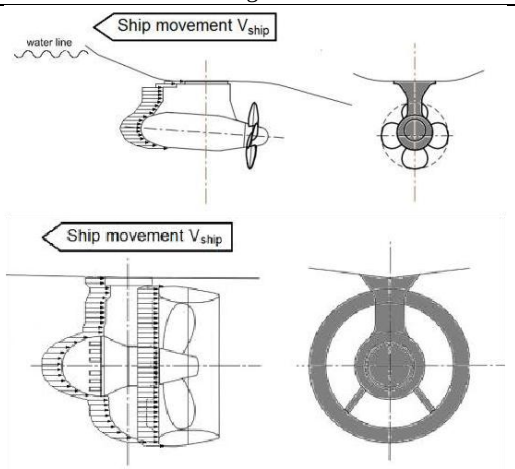
Ice class	B1*	B1	B2	B3
Longitudinal impact in main operational direction (m/s)	6	5	5	5
Longitudinal impact in reversing direction (pushing unit propeller hub or pulling unit cover end cap impact) (m/s)	4	3	3	3
Transversal impact (m/s)	4	3	3	3

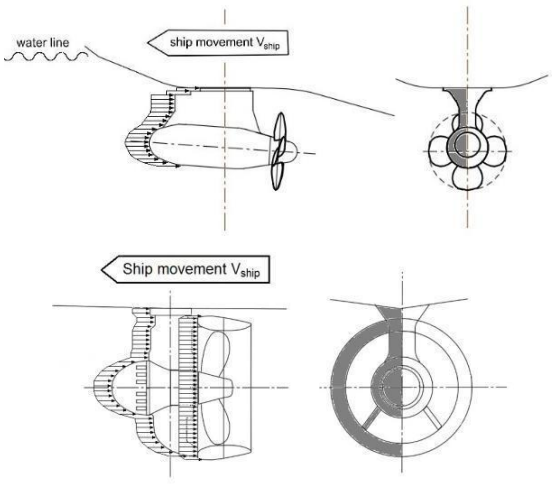
(3) Extreme ice loads on thruster hull when penetrating an ice ridge

In icy conditions, ships typically operate in ice channels. When passing other ships, ships may be subject to loads caused by their thrusters penetrating ice channel walls. There is usually a consolidated layer at the ice surface, below which the ice blocks are loose. In addition, the thruster may penetrate ice ridges when backing. Such a situation is likely in the case of B1* class ships in particular, because they may operate independently in difficult ice conditions. However, the thrusters in ships with lower ice classes may also have to withstand such a situation, but at a remarkably lower ship speed.

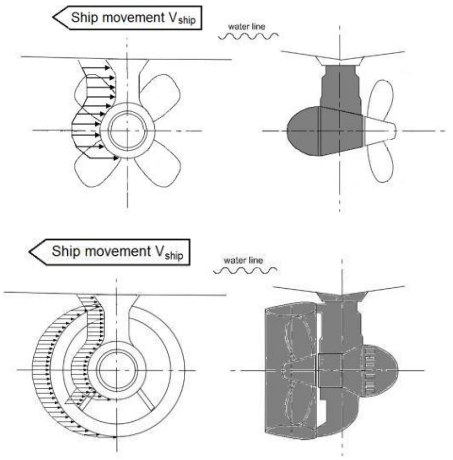
In this load scenario, the ship is penetrating a ridge in thruster first mode with an initial speed. This situation occurs when a ship with a thruster at the bow moves forward, or a ship with a thruster astern moves in backing mode. The maximum load during such an event is considered the extreme load. An event of this kind typically lasts several seconds, due to which the dynamic magnification is considered negligible and is not taken into account.

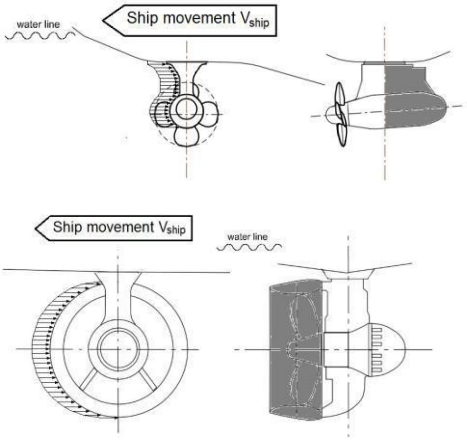
The load magnitude is to be estimated for the load cases shown in Table 14.2.6.5(3)-1, using the equation below. The parameter values for calculations are given in Table 14.2.6.5(3)-2 and Table 14.2.6.5(3)-3. The loads are to be applied as uniform distributed load or uniform pressure over the thruster surface. The design operation speed in ice can be derived from Table 14.2.6.5(3)-2 or Table 14.2.6.5(3)-3. Alternatively, the actual design operation speed in ice of the ship in question can be used.





$$F_{tr} = 32 v_s^{0.66} H_r^{0.9} A_t^{0.74} \qquad \text{kN}$$





where: V_s— ship speed, in m/s;

H_r— design ridge thickness (the thickness of the consolidated layer is 18% of the total ridge thickness), in m;

A_t —projected area of the thruster, in m^2.

Load cases for ridge ice loads Table 14.2.6.5(3)-1

Load case	Force	Loaded area	Figure
Load case T4a Symmetric longitudinal ridge penetration loads	F_{tr}	Uniform distributed load or uniform pressure, which are applied symmetrically on the impact area	
Load case T4b Non-symmetric longitudinal ridge penetration loads	50% of F_{tr}	Uniform distributed load or uniform pressure, which are applied on the other half of the contact area	

Load case	Force	Loaded area	Figure
Load case T5a Symmetric lateral ridge penetration loads for ducted azimuthing unit and pushing open propeller unit	F_{tr}	Uniform distributed load or uniform pressure, which are applied symmetrically on the contact area	
Load case T5b Non-symmetric lateral ridge penetration loads for all azimuthing units	*50% of* F_{tr}	Uniform distributed load or uniform pressure, which are applied on the other half of the contact area	

When calculating the contact area for thruster-ridge interaction, the loaded area in the vertical direction is limited to the ice ridge thickness, as shown in Figure 14.2.6.5(3).

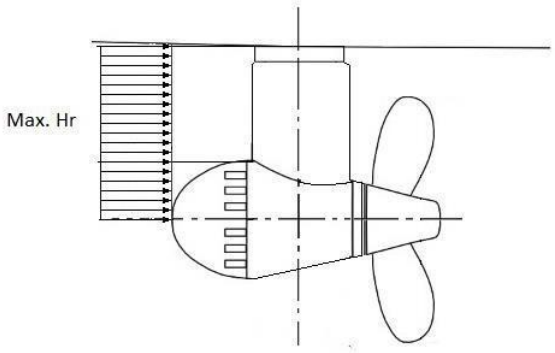


Figure 14.2.6.5(3) Schematic figure showing the reduction of the contact area by the maximum ridge thickness

Parameters for calculating maximum loads when the thruster penetrates an ice ridge (aft thrusters. bow first operation)

Table 14.2.6.5(3)-2

Ice class	B1*	B1	B2	B3

Parameters for calculating maximum loads when the thruster penetrates an ice ridge (thruster first mode such as double acting ships)

Table 14.2.6.5(3)-3

Ice class	B1*	B1	B2	B3
Thickness of the design ridge consolidated layer (m)	1.5	1.5	1.2	1.0
Total thickness of the design ridge, H_r (m)	8	8	6.5	5
Initial ridge penetration speed (longitudinal loads) (m/s)	6	4	4	4
Initial ridge penetration speed (transversal loads) (m/s)	3	2	2	2

(4) Acceptability criterion for static loads

The stresses on the thruster are to be calculated for the extreme once-in-a-lifetime loads described in 14.2.6.5. The nominal von Mises stresses on the thruster body are to have a safety margin of 1.3 against the yielding strength of the material. At areas of local stress concentrations, stresses are to have a safety margin of 1.0 against yielding. The slewing bearing, bolt connections and other components are to be able to maintain operability without incurring damage that requires repair when subject to the loads given in 14.2.6.5(2) and 14.2.6.5(3) multiplied by a safety factor of 1.3.

(5) Thruster body global vibration

Evaluating the global vibratory behavior of the thruster body is important, if the first blade order excitations are in the same frequency range with the thruster global modes of vibration, which occur when the propeller rotational speeds are in the high power range of the propulsion line. This evaluation is mandatory and it is to be shown that there is either no global first blade order resonance at high operational propeller speeds (above 50% of maximum power) or that the structure is designed to withstand vibratory loads during resonance above 50% of maximum power.

When estimating thruster global natural frequencies in the longitudinal and transverse direction, the damping and added mass due to water are to be taken into account. In addition to this, the effect of ship attachment stiffness is to be modelled.

14.2.7 *Alternative designs*

14.2.7.1 Scope

As an alternative to paragraphs 14.2.5 and 14.2.6, a comprehensive design study may be carried out to the satisfaction of the Administration. The study is to be based on ice conditions given for different ice classes in paragraph 14.2.3, and is to include both fatigue and maximum load design calculations and fulfill the pyramid strength principle, as given in paragraph 14.2.6.1.

14.2.7.2 Loading

Loads on the propeller blade and propulsion system are to be based on an acceptable estimation of hydrodynamic and ice loads.

14.2.7.3 Design levels

The analysis is to indicate that all components transmitting random (occasional) forces, excluding propeller blades, are not subjected to stress levels in excess of the yield stress of the component material, with a reasonable safety margin.

Cumulative fatigue damage calculations are to indicate a reasonable safety factor. Due account is to be taken of material properties, stress raisers, and fatigue enhancements.

Vibration analysis is to be carried out and is to indicate that the complete dynamic system is free from

harmful torsional resonances resulting from propeller/ice interaction.

Section 3 STARTING ARRANGEMENTS AND COOLING WATER SYSTEM

14.3.1 *Starting arrangements*

14.3.1.1 The capacity of the air receivers is to comply with the provisions of 9.5.1.6 of this PART. If the air receivers serve any other services than starting the propulsion engine, their capacity is to be adequately increased.

14.3.1.2 The capacity of the air compressors is to comply with the provisions of 9.5.1.2 of this PART. If the ship is intended for Ice Class B1* and its propulsion engine is of reversible type, the charging time specified in 9.5.1.2 of this PART is not to be more than 0.5 h.

14.3.2 *Cooling water system*

14.3.2.1 The cooling water system is to be designed to ensure supply of cooling water when navigating in ice. For this purpose at least one cooling water inlet chest is to be arranged as follows:

(1) The sea inlet is to be situated near the centerline of the ship and well aft if possible.

(2) The chest is to have a sufficient volume. As a guidance for design, the volume of the chest is to be about one cubic metre for every 750 kW of engine output of the ship including the output of the auxiliary engines necessary for the ship's service.

(3) The chest is to be sufficiently high to allow ice to accumulate above the inlet pipe.

(4) A pipe, being of the same diameter as the cooling water discharge pipe, is to be connected between the chest and the cooling water discharge pipe.

(5) The area of the strum holes is not to be less than 4 times the inlet pipe sectional area.

14.3.2.2 If there are difficulties to meet the requirements of 14.3.2.1(2) and (3), two smaller chests may be arranged, but they must comply with the requirements of 14.3.2.1(1) to (5).

14.3.2.3 Heating coils may be installed in the upper part of the chest or chests where necessary.

14.3.2.4 Arrangements for using ballast water for cooling purposes may be used as a reserve in ballast condition but can not be accepted as a substitute for sea inlet chests as described above.

CHAPTER 15 VAPOUR CONTROL SYSTEM

Section 1 GENERAL PROVISIONS

15.1.1 *Application*

15.1.1.1 The requirements of this Chapter are applicable to ships fitted with systems for control of vapour emission from tanks and requesting sub-elements① as defined in 15.1.2, such as oil tankers and chemical tankers, etc.

15.1.1.2 In addition to the requirements of this Chapter, attention is to be given to any relevant regulations (if any) of the Administration of the flag States in which the ship is to be registered.

15.1.2 *Sub-elements*

15.1.2.1 Ships fitted with systems for control of vapour emission from cargo tanks complying with all requirements of this Chapter (other than Section 4) may be assigned to the following sub-elements:

VCS

15.1.2.2 Ships fitted with systems for control of vapour emission from cargo tanks complying with all requirements of this Chapter may be assigned to the following sub-elements:

VCS-T

15.1.3 *Definitions*

15.1.3.1 For the purpose of this Chapter:

(1) **Diluted** means a flammable gas or mixture is defined as diluted when its concentration in air is less than 50% of its lower explosive limit.

(2) **Flammable cargoes** are crude oils, petroleum products and chemicals having a flashpoint not exceeding 60℃ (closed cup test) and a Reid vapour pressure which is below the atmosphere pressure, and other substances having equivalent fire risk.

(3) **Inerted** is the condition in which the oxygen content in a flammable gas/air mixture is 8% or less by volume.

(4) **Independent** is suitable for two electrical systems which are considered independent when any one system may continue to operate with a failure of any part of the other system, except the power source and electrical feeder panels.

(5) **Maximum transfer rate** is the maximum volumetric rate at which a ship may receive cargo or ballast.

(6) **Service ship** is a ship which receives and transports liquid cargoes between a facility (shore station) and another ship and vice versa.

(7) **Lightering operation** is the operation of transferring liquid cargo from one ship to one service ship.

(8) **Topping-off** is the operation of transfer of liquid cargo from a service ship to another ship in order to load the receiving ship at a deeper draft.

(9) **Ship vapour connection** is the point of interface between the ship's fixed vapour collection system and the collection system of a facility or another ship. Hoses or loading arms on board, carried for the purpose of these Rules, are considered part of the vapour control system of the ship.

(10) **Terminal vapour connection** is that point at which the terminal vapour collection system is connected to a vapour collection hose or arm.

(11) **Vapour balancing** is the transfer of vapour displaced by incoming cargo from the tank of a ship receiving cargo into a tank of a facility delivering cargo via a vapour collection system.

(12) **Vapour collection system** is an arrangement of piping and hoses used to collect vapour emitted from a ship's cargo tank and to transport the vapour to a vapour processing unit.

(13) **Vapour processing unit** is that component of a vapour control system that recovers or destroys vapour collected from a ship.

15.1.4 *Plans and documents*

15.1.4.1 The following plans and documents are to be submitted for approval by ships for which the sub-elements of VCS or VCS-T is requested:

(1) Diagrammatic plan of the vapour piping system, indicating material specifications, scantlings, ratings, joining details and fittings;

(2) Diagrammatic plan of the gauging system and overfill protection, indicating manufacturer and type of

① Sub-elements: refer to Table 1.3.3.1 of Chapter 1 of Rules for Green Eco-ships.

the equipment or instruments, hazardous area locations, location of electrical equipment in gas–dangerous spaces and safe certificates of the electrical instruments intended to be used in hazardous locations, electrical schemes concerning the alarm system supply, electrical schemes concerning the intrinsically safe circuits;

(3) Diagrammatic plan of the venting system, indicating necessary data for verifying the venting capacity of the pressure/vacuum valves;

(4) Pressure drop calculation comparing cargo transfer rates versus pressure drops from the farthest tanks to the vapour connection, including any possible hoses;

(5) Calculations showing the time available between alarm setting and overfill at maximum loading rate for each tank;

(6) Instruction manual.

15.1.4.2 The following additional plans and documents are also to be submitted for reference by ships for which the sub-elements of VCS-T is requested:

Information on the anti-detonation devices, including manufacturer and type of the device employed as well as documentation on any acceptance tests carried out.

Section 2 VAPOUR PIPING SYSTEMS

15.2.1 *General requirements*

15.2.1.1 Each ship is to have vapour collection piping permanently installed, with the tanker vapour connection located as close as practical to the loading manifolds.

Chemical tankers are permitted to have a permanent vapour connection at each cargo tank for connection to a vapour hose which is to be kept as short as practicable, and in no case longer than 3 m.

15.2.1.2 If a tanker simultaneously collects vapour from incompatible cargoes, it is to keep these incompatible vapours separate throughout the entire vapour collection system.

15.2.1.3 Vapour collection piping is to be electrically bonded to the hull and is to be electrically continuous.

15.2.1.4 Means are to be provided to eliminate liquid condensate which may collect in the system. In general, a draining valve is to be fitted in each low point of the line and the condensate is led to an appropriate collection, such as catcher groove, slop tank.

15.2.1.5 When inert gas distribution piping is used for vapour collection piping, means to isolate the inert gas supply from the vapour collection system are to be provided. The isolation device is to comply with the requirements of Chapter 4, PART SIX of the Rules.

15.2.1.6 The vapour collection system is not to interfere with the proper operation of the cargo tank venting system. However, vapour collection piping may be partly common with the vent piping or the inert gas system piping.

15.2.1.7 External connection flange of the vapour collection system is to be fitted with a permanently protruding stud in way of 12 o'clock position on the pitch circle of bolt hole with 12.7 mm in diameter and at least 25.4 mm in length.

15.2.2 *Vapour manifold*

15.2.2.1 An isolation valve capable of manual operation is to be provided at the ship vapour connection, the valve position is to be readily determined visually (open/closed indication).

15.2.2.2 Each vapour manifold is to be for the last 1m in front of external connection flange painted on its exterior surfaces with red/yellow/red. The red bands are 100 mm wide, the yellow in the center is 800 mm wide and labeled "VAPOUR" in black letters at least 50 mm high.

15.2.3 *Vapour hoses*

15.2.3.1 Each hose used for transferring vapour is to have:

(1) a maximum working pressure of at least 0.035 MPa;

(2) the capacity of withstanding at least 0.014 MPa vacuum without collapsing or constricting;

(3) a design burst pressure of at least 0.175 MPa;

(4) electrical continuity with a maximum resistance of 10 kΩ;

(5) resistance to abrasion and kinking;

(6) the last 1 m of each end of the hose marked in accordance with 15.2.2.2.

15.2.3.2 Vapour hose handling equipment is to be provided with hose saddles which provide adequate support to prevent kinking or collapse of hoses.

15.2.4 *High and low vapour pressure protection*

15.2.4.1 The cargo tank venting system is to be capable of discharging cargo vapour at 1.25 times the maximum transfer rate in such a way that the pressure in the vapour space of each tank connected to the vapour collection system does not exceed the maximum working pressure of the tank or the operating pressure/burst pressure of a safety valve or rupture disk, if fitted.

15.2.4.2 It is not to relieve at a pressure corresponding to a pressure in the cargo tank vapour space of less than 0.007 MPa.

15.2.4.3 Means are to be provided to prevent a vacuum in the cargo tank vapour space that exceeds the maximum design vacuum for any tank which is connected to the vapour collection system, when the tank is discharged at the maximum rate.

15.2.4.4 It is not to relieve at a vacuum corresponding to a vacuum in the cargo tank vapour space less than 0.0035 MPa below the atmospheric pressure.

15.2.4.5 Pressure/vacuum safety valves are to be fitted with means to check that the device operates freely and does not remain in the open position.

15.2.4.6 Pressure/vacuum safety valves are to be fitted with a flame screen at their outlets, unless the vapour discharge velocity is not less than 30 m/s.

15.2.4.7 A venting testing is to be carried out for the pressure/vacuum safety valves before being fitted. Where it is intended to comply with the requirements of 15.2.4.6, a flame screen is to be fitted when in testing.

Section 3 INSTRUMENTATION

15.3.1 *Cargo tank gauging equipment*

15.3.1.1 Each cargo tank that is connected to a vapour collection system is to be equipped with a cargo gauging device which:

(1) provides a closed gauging arrangement which does not require opening the tank to the atmosphere during cargo transfer;

(2) allows the operator to determine the liquid level in the tank for the full range of liquid levels in the tank;

(3) indicates the liquid level in the tank, at the position where cargo transfer is located;

(4) if possible, is installed in tank during the entire transfer operation.

15.3.2 *Cargo tank high level alarms*

15.3.2.1 Each cargo tank that is connected to a vapour collection system is to be equipped with an intrinsically safe high level alarm system which alarms before the tank overfill alarm, but not lower than 95% of the tank capacity.

15.3.2.2 The high level alarm is to be capable of giving audible and visual alarm indications at the cargo transfer control room. It is to be identified with the black letters “HIGH LEVEL ALARM” with at least 50 mm high.

15.3.2.3 The high level alarm is to be independent of the overfill alarm.

15.3.2.4 The high level alarm is to alarm in the event of loss of power to the alarm system or failure of the electric circuits to the tank level sensors.

15.3.2.5 The high level alarm is to be able to be checked at the tank of proper operation prior to each transfer or contain an electronic self-testing feature which monitors the condition of the alarm circuits and sensors.

15.3.3 *Cargo tank overfill alarms*

15.3.3.1 Each cargo tank that is connected to a vapour collection system is to be equipped with an intrinsically safe overfill alarm which alarms early enough to allow the person in charge of transfer operation to stop such operation before the cargo tank overflows.

In general, the setting of cargo tank overfill alarm is not to exceed 98.5% of the tank capacity, and the time between alarm setting and overfill is not to be less than 1 min.

15.3.3.2 The overfill alarm is to be given audible and visual alarm indications at the cargo transfer control room and in the deck cargo area, and the audible and visual alarm indications can also be seen and heard at most positions. It is to be identified with the black letters “OVERFILL ALARM” with at least 50 mm high.

15.3.3.3 The overfill alarm is to be independent of both the high level alarm and the cargo gauging system.

15.3.3.4 The overfill alarm is to alarm in the event of loss of power to the alarm system or failure of the electric circuits to the tank level sensors.

15.3.3.5 The overfill alarm is to be able to be checked at the tank of proper operation prior to each transfer or contain an electronic self-testing feature which monitors the condition of the alarm circuits and sensors.

15.3.4 *High and low vapour pressure alarms*

15.3.4.1 Each vapour collection system is to be fitted with one or more pressure sensing devices that sense the pressure in the main collection line, and which:

(1) have a pressure indicator and audile and visual alarm indications located in the cargo transfer control room;

(2) alarm the high pressure at not more than 90% of the lowest relief valve setting in the tank venting system;

(3) alarm at a low pressure of not less than 0.001 MPa (100 mm WG) for an inerted tank, or the lowest vacuum relief valve setting in the cargo venting system for a non-inerted tank.

15.3.4.2 Pressure sensors fitted in each cargo tank are acceptable as equivalent to pressure sensors fitted in each main vapour collection line.

Section 4 ADDITIONAL REQUIREMENTS FOR VCS-T

15.4.1 *Application*

15.4.1.1 The requirements of this Section are applicable to service ships.

15.4.2 *General requirements*

15.4.2.1 If the cargo tanks on a ship discharging cargo and a ship receiving cargo are inerted, the service ship is to have a means to inert the vapour transfer hose prior to transferring cargo vapour and an oxygen analyzer with a sensor or sampling connection fitted within 3 m of the ship vapour connection which:

(1) activates an audible and visual alarm at the cargo transfer control room on the service ship where the oxygen content in the vapour collection system exceeds 8% by volume;

(2) has an oxygen concentration indicator at the cargo transfer control room on the service ship;

(3) has a connection for injecting a span gas of known concentration for calibration and testing of the oxygen analyzer.

15.4.2.2 If the cargo tanks on a ship discharging cargo are not inerted, the vapour collection line on the service ship is to be fitted with an approved detonation arrester located within 3 m of the ship vapour connection.

15.4.2.3 An electrical insulating flange or one length of non-conductive hose is to be provided between the ship vapour connection on the service ship and the vapour connection on the ship being lightered or topped off.

Section 5 INSTRUCTION MANUAL

15.5.1 *General requirements*

15.5.1.1 Each ship utilizing a vapour emission control system is to be provided with a detailed instruction manual.

15.5.1.2 Instructions are to encompass the purpose and principles of operation of the vapour emission control system and provide an understanding of the equipment involved and associated hazards. In addition, the instructions are to provide an understanding of the operating procedures, piping connection sequence, start-up procedures, normal operations and emergency procedures.

15.5.2 *Content*

15.5.2.1 The instructions are to contain:

(1) a line diagram of the tanker's vapour collection piping including the location of all valves, control devices, pressure-vacuum safety valves, pressure indicators, flame arresters and detonation arresters, if fitted;

(2) the maximum transfer rate for each group of cargo tanks having the same venting line, determined as the lowest of the following:

① 80% of the total venting capacity of the pressure relief valves in the cargo tank venting system;

② the total vacuum relieving capacity of the vacuum relief valves in the cargo tank venting system;

③ the rate based on pressure drop calculations at which, for a given pressure at the facility (shore station) vapour connection, or, if lightering, at the vapour connection of the service ship, the pressure in any cargo tank connected to the vapour collection system exceeds 80% of the setting of any pressure relief valve in the cargo tank venting system;

(3) the initial loading rate for each cargo tank, to be determined in such a way as to minimize the development of a static electrical charge, where applicable;

(4) tables or graphs of transfer rates (and corresponding vapour collection system pressure drops through the vapour hoses, if foreseen) determined from the most remote cargo tanks to the ship vapour connection as follows:

① for each cargo handled by the vapour collection system at the maximum and the lowest transfer rates;

② based on 50% cargo vapour and air mixture, and a vapour growth rate appropriate for the cargo being loaded.

CHAPTER 16 ADDITIONAL REQUIREMENTS FOR MACHINERY INSTALLATIONS OF SMALL SHIPS

Section 1 GENERAL PROVISIONS

16.1.1 *Application*

16.1.1.1 The provisions of this Chapter apply to the machinery installations of small ships and such provisions may substitute those fore-mentioned relevant provisions of this PART.

Section 2 ADDITIONAL REQUIREMENTS FOR MACHINERY INSTALLATIONS

16.2.1 *Dead ship starting*

16.2.1.1 Cargo ships of less than 500 gross tonnage may not be required by 1.2.6 of this PART.

16.2.2 *Boiler arrangement*

16.2.2.1 For cargo ships of less than 500 gross tonnage, if effective heat-insulating measures are taken, the clearance between the boilers and the fuel oil tank boundaries as required in 1.3.2.2 of this PART may be suitably reduced.

16.2.3 *Bilge suction arrangement in machinery spaces*

16.2.3.1 For ships of less than 500 gross tonnage, the number of direct bilge suctions in Table 3.3.2.1 of this PART may be changed to 1. The number of branch suction may be changed to 2.

For ships of less than 100 gross tonnage, the number of branch suction in Table 3.3.2.1 of this PART may be changed to 1.

16.2.3.2 For cargo ships of less than 500 gross tonnage or passenger ships of less than 100 gross tonnage engaged on non-international voyage or passenger ships of less than 500 gross tonnage and with service category 3 engaged on non-international voyage, emergency bilge suction as required in 3.3.3.1 of this PART may be dispensed with.

16.2.4 *Bilge pumps and bilge piping*

16.2.4.1 The number of power bilge pumps and drive modes for each ship as specified in Table 3.4.1.1 of this PART may be required for the following ships:

(1) for passenger ships engaged on non-international voyages of less than 100 gross tonnage, carrying not more than 100 passengers, 2 independent bilge pumps may be provided if navigation period is less than 4 h;

(2) for cargo ships of less than 100 gross tonnage, one of power driven type and one hand pump may be provided.

16.2.4.2 For ships of 25 m or less in length, the internal diameter of branch bilge pipes as required in 3.4.3.4 of this PART may be reduced to 40 mm.

16.2.4.3 For ships of 60 m or less in length, the internal diameter of branch bilge pipes to the tunnel wells as required in 3.4.3.6 of this PART may be reduced to 50 mm.

16.2.4.4 For ships of less than 500 gross tonnage, the capacity of bilge wells for machinery and boiler spaces and cargo holds as specified in 3.4.8.1 of this PART may be suitably reduced but not to be less than 0.10 m^3.

16.2.4.5 For ships of less than 100 gross tonnage, the ends of bilge suction in machinery spaces as specified in 3.4.8.2 of this PART may be fitted with a strum box instead of a mud box.

16.2.5 *Fuel oil daily tank*

16.2.5.1 The requirements of 4.2.1.8 of this PART do not apply to cargo ships of less than 500 gross tonnage.

16.2.6 *Oil burning units of boilers*

16.2.6.1 For cargo ships of less than 500 gross tonnage, for auxiliary boilers for essential services or auxiliary boilers supplying steam for heating heavy fuel oil as specified in 4.2.2.2 of this PART, one oil supply unit will be accepted.

16.2.7 *Oil fuel booster pumps*

16.2.7.1 For ships of less than 500 gross tonnage, the standby pump or spare pump as required in 4.2.3.1 of this PART may be dispensed with.

16.2.8 *Feed water pumps for boilers*

16.2.8.1 For cargo ships of less than 500 gross tonnage, for auxiliary boilers for essential services or auxiliary boilers supplying steam for heating heavy fuel oil and cargo oil as specified in 4.4.1.1 of this PART, only one feed water pump fitted is acceptable.

16.2.9 *Feed water systems for boilers*

16.2.9.1 For auxiliary boilers fitted with only one feed water pump as required in 16.2.8 of this Chapter, the requirements for provision of two independent feed water systems in 4.4.2.1 of this PART are not applicable.

16.2.10 *Condensate pumps*

16.2.10.1 For cargo ships of less than 500 gross tonnage, if not propelled by steam, for condensate pumps mentioned in 4.4.4.1 of this PART, the standby pump or spare pump is dispensed with.

16.2.11 *Cooling water pumps*

16.2.11.1 For cargo ships of less than 500 gross tonnage, the standby pump or spare pump as required in 4.5.1.1 of this PART is dispensed with.

16.2.12 *Bilge lines of oil tankers*

16.2.12.1 For oil tankers of less than 150 gross tonnage, the cargo pump room bilge specified in 5.3.2.1 of this PART may be drained by means of a hand pump having a 50 mm bore suction.

16.2.13 *Oil tank air pipes*

16.2.13.1 Paragraph 3.10.2.5 of this PART does not apply to cargo ships of less than 500 gross tonnage.

16.2.14 *Oil tank short sounding pipes*

16.2.14.1 For fuel oil tanks in double bottom tanks, when the sounding pipes are terminated in machinery spaces, only requirements of 3.10.10.1(2) and (3) are to be met for cargo ships of less than 500 gross tonnage.

CHAPTER 1 GENERAL

Section 1 GENERAL PROVISIONS

1.1.1 General requirements

1.1.1.1 Unless otherwise specified, the requirements of this PART apply to electrical installations intended for sea-going ships.

1.1.1.2 Electrical propelling machinery and associated equipment together with auxiliary services essential for the safety of the ship are to be constructed and installed in accordance with the relevant requirements of this PART, inspected and tested by the Surveyors. In addition, construction and testing of the electrical equipment are to comply with the relevant acceptable standards.

1.1.1.3 The design and installation of the electrical equipment other than those specified in 1.1.1.2 of this Section is to be such that risk of fire due to its failure is minimized, and it is at least to comply with the acceptable standards to be revised where necessary for ambient conditions.

1.1.1.4 In addition, the electrical installations are to comply with the applicable requirements in PART ONE of the Rules.

1.1.1.5 The electrical installations are to be such that:

(1) all electrical auxiliary services necessary for maintaining the ship in normal operational and habitable conditions will be ensured without recourse to the emergency source of electrical power;

(2) electrical services essential for safety will be ensured under various emergency conditions;

(3) the safety of passengers, crew and ship from electrical hazards will be ensured.

1.1.2 Definitions

1.1.2.1 For the purpose of this PART:

(1) Essential services are the equipment necessary for the propulsion, steering and safety of the ship and the special equipment on ships with special class notations, including:

① primary essential services which need to be in continuous operation for maintaining propulsion and steering:

(a) steering gear;

(b) controllable pitch propeller installation;

(c) scavenging air blowers, fuel oil supply pumps, fuel valve cooling pumps, lubricating oil pumps and cooling water pumps for main and auxiliary engines and turbines required for propulsion;

(d) forced draught fans, feed water pumps, water circulating pumps, vacuum pumps, condensate pumps and oil burning installations for auxiliary steam boilers for the operation of primary essential services and for steam plants on steam turbine ships;

(e) azimuth thrusters which are the sole means for propulsion/steering with lubricating oil pumps, cooling water pumps;

(f) electrical equipment for electric propulsion plant with lubricating oil pumps and cooling water pumps;

(g) electric generators and associated power sources supplying the equipment mentioned in (a) to (f) above;

(h) hydraulic pumps supplying the equipment mentioned in (a) to (f) above;

(i) viscosity control equipment for heavy fuel oil;

(j) fire pumps and other extinguishing medium pumps;

(k) navigation lights, aids and signals;

(l) internal safety communication equipment;

(m) lighting system;

(n) control, monitoring and safety devices/systems for equipment mentioned in (a) to (m) above;

② secondary essential services which need not necessarily be in continuous operation for maintaining propulsion and steering, but which are necessary for maintaining the ship's safety, e.g.:

(a) windlasses;

(b) fuel oil transfer pumps and fuel oil treatment equipment;

(c) lubricating oil transfer pumps and lubricating oil treatment equipment;

(d) pre-heaters for heavy fuel oil;

(e) starting air and control air compressors;

(f) bilge, ballast and heeling pumps;

(g) ventilating fans for engine and boiler rooms;

(h) equipment necessary for maintaining dangerous spaces in a safe condition;
(i) fire detection and alarm system;
(j) watertight closing appliances;
(k) refrigerating equipment for lowering ambient air temperature (see 1.2.1.2 of this Chapter);
(l) electric generators and associated power sources supplying the equipment mentioned in (a) to (k) above;
(m) hydraulic pumps supplying the equipment mentioned in (a) to (k) above;
(n) control, monitoring and safety systems for cargo containment systems;
(o) control, monitoring and safety devices/systems for equipment mentioned in (a) to (m) above;

③ special equipment of ships with a special class notation that may be regarded as essential services.

(2) Non-essential services are those whose temporary disconnection will not impair propulsion and steer of the ship, nor endanger the safety of passengers, crew, cargo, ship and machinery.

(3) Emergency consumer is a consumer which, after loss of the main source of electrical power, must be supplied by the emergency source of electrical power.

(4) Main source of electrical power is a source intended to supply electrical power to the main switchboard for distribution to all services necessary for maintaining the ship in normal operational and habitable condition.

(5) Emergency source of electrical power is a source of electrical power, intended to supply the emergency switchboard in the event of failure of the supply from the main source of electrical power.

(6) Dead ship condition is the condition under which the main propulsion plant, boilers and auxiliaries are not in operation and in restoring the propulsion, no stored energy for starting and operating the propulsion plant, the main source of electrical power and other essential auxiliaries is assumed to be available.

(7) Primary distribution system is a system having electrical connection with the generator.

(8) Secondary distribution system is a system having no electrical connection with the generator, e.g. isolated therefrom by a double-wound transformer.

(9) Low-voltage system is an alternating-current system operating with the maximum rated voltage not exceeding 1,000 V inclusive between conductors and with the rated frequency of 50 Hz or 60 Hz, or a direct-current system with the maximum instantaneous voltage under rated operating conditions does not exceed 1,500 V between conductors.

(10) High-voltage system is an alternating-current system operating with the rated voltage more than 1 kV but not exceeding 15 kV and with the rated frequency of 50 Hz or 60 Hz, or a direct-current system with the maximum instantaneous voltage under rated operating conditions exceed 1,500 V between conductors.

(11) Switch gear and control gear assembly is a combination of one or more switch gears and means of control, measurement, signal, protection and adjustment etc, assembled by the manufacturer together with all internal electrical and mechanical connectors and components.

(12) Main switchboard is a switchboard which is directly supplied by the main source of electrical power and is intended to control and distribute electrical energy to switch gear and control gear assemblies of the ship's services.

(13) Emergency switchboard is a switchboard which, normally supplied by the main switchboard, in the event of failure of the main electrical power supply system is directly supplied by the emergency source of electrical power or the transitional source of emergency power and is intended to control and distribute electrical energy to switch gear and control gear assemblies of the ship's emergency services.

(14) Distribution board is a switch gear and control gear assembly arranged for the control and distribution of electrical power to final sub-circuits.

(15) Final sub-circuit is that portion of a wiring system extending beyond the final over-current device of a board.

(16) Total discrimination (total selectivity) is an over-current discrimination where, in the presence of two or more over-current protection devices in series, the protective device on the load side effects the protection without causing the other protective devices to operate.

(17) Partial discrimination (partial selectivity) is an over-current discrimination where, in the presence of two or more over-current protective devices in series, the protective device on the load side effects the protection up to a given level of short-circuit current, without causing the other protective devices to operate.

(18) Back-up protection is the protection equipment or system which is intended to operate when a system fault is not cleared in due time because of failure or inability of the protective device closest to the fault to operate or because of failure of the other protective device.

(19) Continuity of power supply means that during and after a fault in a circuit, the supply to fault-free circuits is permanently ensured.

(20) Dangerous zone is a zone where flammable or explosive vapours, gases, dusts, or explosives may be

normally expected to accumulate.
(21) Enclosed space is a space enclosed by bulkheads and decks, which may be fitted with doors, windows or other openings capable of being closed.
(22) Semi-enclosed space is a space limited by top plates, wind breaks and bulkheads etc. in such a manner that the natural conditions of ventilation in the space are notably different from those obtained on open deck, and so arranged that the gas will not easily diffuse.
(23) A blackout situation means that the main and auxiliary machinery installations, including the main power supply, are out of operation, but the services for bringing them into operation (e.g. compressed air, starting current from batteries, etc.) are available.
(24) Shelf life of a battery means the duration of storage under specified conditions at the end of which a battery retains the ability to give a specified performance.
(25) An air-lock is to have two gastight steel doors which are self-closing without any hold-back arrangement, and the distance between which is not to be less than 1.5 m and not necessarily more than 2.5 m.
(26) Ripple voltage
The amplitude of the ripple voltage is represented in Figure 1.1.2.1(26) by the difference between U_{max} and $U_{min.}$

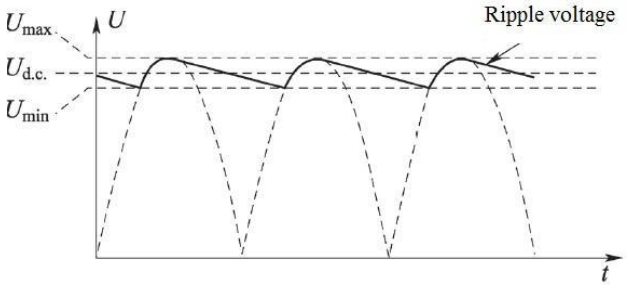

Figure 1.1.2.1(26) Ripple Voltage

(27) Uninterruptible power system (UPS) is a combination of converters, switches and energy storage means, for example batteries, constituting a power system for maintaining continuity of load power in case of input power failure.
(28) Off-line UPS unit is a UPS unit where under normal operation the output load is powered from the bypass line (raw mains) and only transferred to the inverter if the bypass supply fails or goes outside preset limits. This transition will invariably result in a brief (typically 2 to 10 ms) break in the load supply. See Figure 1.1.2.1(28).

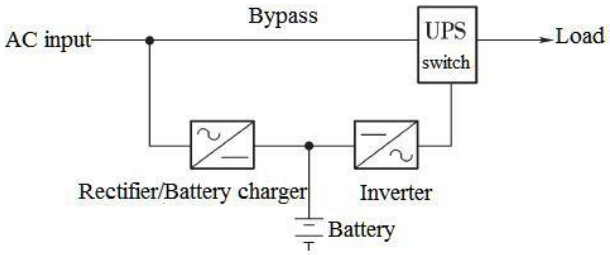

Figure 1.1.2.1(28) Off-Line UPS Unit

(29) Line interactive UPS unit is an off-line UPS unit where under normal operation the output load is powered from the UPS inverter or the power interface and when the input power goes outside the preset voltage and frequency limits, the load is transferred to stored energy power and the input power is disconnected from the power interface. See Figure 1.1.2.1(29).

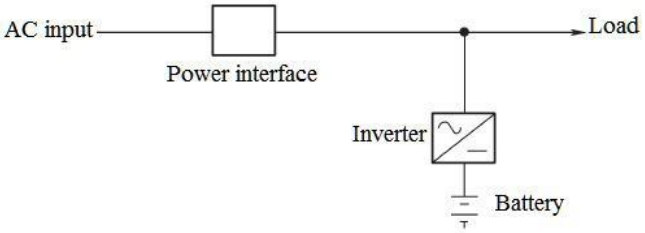

Figure 1.1.2.1(29) Line Interactive UPS Unit

(30) On-line UPS unit is a UPS unit where under normal operation the output load is powered from the inverter, and will therefore continue to operate without break in the event of the supply input failing or going outside preset limits. See Figure 1.1.2.1(30).

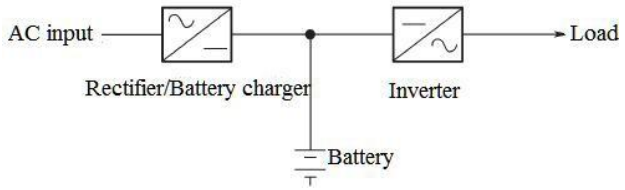

Figure 1.1.2.1(30) On-Line UPS Unit

(31) Zone 0 is an area in which an explosive gas atmosphere is present continuously or for long periods.
(32) Zone 1 is an area in which an explosive gas atmosphere is likely to occur in normal operation.
(33) Zone 2 is an area in which an explosive gas atmosphere is not likely to occur in normal operation and, if it does occur, is likely to do so only infrequently and will exist for a short period only.

1.1.3 Plans and documents

1.1.3.1 The following plans and documents are to be submitted for approval:
(1) Electrical loading evaluation of main and emergency sources of electrical power.
(2) Calculations for short-circuit currents (for ships with operational conditions of generators having a total capacity (including single generator operation, long-term parallel operation and short-term parallel transferred load)of more than 250 kVA).
(3) Analysis for coordination of protective devices in compliance with the requirements of 2.5.1.1 and 2.5.4.1 of this PART (for ships with operational conditions of generators having a total capacity (including single generator operation, long-term parallel operation and short-term parallel transferred load) of more than 250 kVA,which may be omitted for non-self-propelled ships).
(4) Diagrams of power systems, in which the following are to be indicated:
① main ratings of motors, transformers, batteries, electrical and electronic equipment;
② all feeders connected to main and emergency switchboards;
③ section boards (if fitted) and distribution boards;
④ type, cross-sectional area and current loadings of cables;
⑤ rating and setting of protective devices (such as short-circuit, overloading, reverse power and unloading protection);
⑥ remote stops;
⑦ insulation level monitoring and alarm;
⑧ interlocks..
(5) Arrangement of main electrical equipment, in which the positions of the following items are to be indicated:
① main and emergency generators;
② main and emergency switchboards (or emergency accumulator battery charging and discharging boards);
③ emergency accumulator batteries;
④ electrical equipment for essential services (see 1.1.2.1 of this Chapter).
(6) Schematic diagrams of main lighting.
(7) Arrangement of main lighting.
(8) Schematic diagrams of emergency lighting, temporary emergency lighting (if fitted), and additional emergency lighting (if fitted).
(9) Arrangement of emergency lighting, temporary emergency lighting (if fitted), and additional emergency lighting (if fitted).
(10) Schematic diagrams (if supplied by emergency power) of low location lighting (if fitted).
(11) Schematic diagrams of internal communication systems, including:
① engine-room telegraph system;
② essential telephone system;
③ communication system for lifesaving;
④ engineers' alarm system.
(12) Arrangement of internal communication systems, including:

① engine-room telegraph system;
② essential telephone system;
③ communication system for lifesaving;
④ engineers' alarm system.

(13) Schematic diagrams of safety systems for the ship and persons on board, including:
① general emergency alarm system;
② public address system;
③ fire detection and fire alarm systems;
④ alarm system for closing watertight doors;
⑤ other alarm systems, e.g. for the release of fire extinguishing media (see Section 9, Chapter 2 of this PART).

(14) Arrangement of safety systems for the ship and persons on board, including:
① general emergency alarm system;
② public address system;
③ fire detection and alarm system;
④ alarm system for closing watertight doors;
⑤ other alarm systems, e.g. for the release of extinguishing media (see Section 9, Chapter 2 of this PART).

(15) Arrangement of main cable runs (for passenger ships and high voltage electrical installations).

(16) General arrangement of the ship showing dangerous zones and spaces (for oil tankers and other ships carrying dangerous explosive goods).

(17) Simplified circuit diagram of electrical propulsion system, in which the following are to be indicated:
① main ratings of motors, transformers, batteries, electrical and electronic equipment;
② type, cross-sectional area and current loadings of cables;
③ type and main rating of circuit breakers and fuses;
④ earth fault monitoring.

(18) Arrangement of control positions and stations of electrical propulsion machinery.

(19) List of monitoring and alarm items for electrical propulsion.

(20) Arrangement of semiconductor converters, including cooling system, for electrical propulsion system.

(21) Calculations of harmonic distortion for all main connectors, including main switchboards and distribution boards, in the electrical system of electrically propelled ships.

(22) Electrical system and general arrangement of water level detection systems for cargo holds, ballast tanks and dry spaces of bulk carriers.

(23) All electrical equipment located in hazardous areas together with the following associated information are to be included in their arrangement plan:
① type of protection, explosion group and temperature class;
② degree of protection;
③ hazardous classification of the area where the electrical equipment is installed.

(24) Verification information[①] of intrinsically safe circuits, including the verification of the voltage, current, inductance and capacitance.

1.1.3.2 The specifications for all electrical systems of the ship may be submitted for information and additional plans and documents may be required as deemed necessary.

1.1.4 Testing

1.1.4.1 Electrical equipment specified in 1.1.1.2 and 1.1.2.1(1) of this Section is to be tested in accordance with the requirements of Chapter 3 of this PART at the manufacturer. Tests other than those specified in this PART may be required as deemed necessary.

1.1.4.2 On completion of installation on board, the electrical installations are to be subject to mooring and sea trials in accordance with the test programmes approved by ISC.

---

① The maximum inductance and capacitance which are the total of the cable out to the hazardous area plus the values of connected equipment are to be less than the rated values of associated apparatus. The values of permissible input voltage, input current of each intrinsically safe apparatus is to be greater than or equal to the values respectively of the associated apparatus. Refer to IEC publication 60079-14: "Explosive atmosphere-Part 14: Electrical installations design, selection and erection" or equivalent standards.

Section 2 OPERATING CONDITIONS

1.2.1 Environmental conditions

1.2.1.1 Unless otherwise specified (e.g. in 1.2.1.2 of this Section), all electrical installations are to operate satisfactorily under the following environmental conditions:

(1) The ambient air temperatures and primary cooling water temperatures are as given in Table 1.2.1.1(1), however the upper limit of ambient air temperatures for the electronic equipment is to be 55℃.

Ambient Temperature **Table 1.2.1.1(1)**

Medium	Location	Temperature (℃)	
		Unrestricted service	Restricted service except in tropical zones
Air	In enclosed spaces	0 ~ 45	0 ~ 40
	In spaces subject to temperatures over 45℃(or 40℃) or below 0℃	According to temperatures in such spaces	According to temperatures in such spaces
	On the open deck	-25 ~ 45	-25 ~ 40
Water		32	25

(2) The inclination and roll of the ship is as given in Table 1.2.1.1(2).

Angle of Inclination **Table 1.2.1.1(2)**

Installations, components	Angle (°) ①②			
	Athwartships		fore-and-aft	
	Static	Dynamic	Static	Dynamic
Emergency power installations, switchgear, electrical and electronic appliances	22.5	22.5	10	10
Electrical installations excluding items stated above	15	22.5	5	7.5

Notes: ① Athwartship and fore-and-aft inclinations may occur simultaneously.

② For ships carrying liquefied gases or chemicals, the emergency source of electrical power is also to remain operable with the ship being flooded to a final athwartship inclination up to a maximum of 30°.

(3) The vibration and shock likely to arise in normal service of the ship.

(4) Moisture, sea air, oil vapour and mould.

1.2.1.2 Where electrical equipment is installed within environmentally controlled spaces, the ambient temperature for which the equipment is suitable may be reduced from 45℃ to a value not less than 35℃ provided:

(1) the equipment is not for use for emergency services;

(2) temperature control is achieved by at least two cooling units so arranged that, in the event of loss of one cooling unit for any reason, the remaining unit(s) is capable of satisfactorily maintaining the design temperature;

(3) the equipment is able to be initially set to work safely within a 45℃ ambient temperature until such a time that the lesser ambient temperature may be achieved; the cooling equipment is to be rated for a 45℃ ambient temperature;

(4) audible and visual alarms are provided, at a continually manned control station, to indicate any malfunction of the cooling units;

(5) it is to be ensured that electrical cables for their entire length are adequately rated for the maximum ambient temperature to which they are exposed along their length.

1.2.2 Voltage and frequency variations

1.2.2.1 The electrical equipment supplied from the main or emergency systems is to be capable of operating satisfactorily under normally occurring variations in voltage and frequency.

1.2.2.2 Unless otherwise stated in international standards, electrical equipment is to operate satisfactorily with the variations in voltage and frequency from the rated value shown in Table 1.2.2.2 (measured at input terminals of the equipment).

Voltage and Frequency Variations **Table 1.2.2.2**

Equipment	Parameters	Permanent (%)	Transient	
			%	Max. recovery time (s)
General AC equipment	Voltage	+6 ~ -10	±20	1.5
	Frequency	±5	±10	5
Direct current equipment supplied by DC generators or rectifiers	Voltage	±10	–	–
	Voltage cyclic variation deviation	5	–	–
	Voltage ripple	10	–	–
Equipment supplied by batteries: Connected to batteries during charging① Not connected to the batteries during charging	 Voltage Voltage	 +30 ~ -25 +20 ~ -25	–	–

Note: ① Different voltage variations as determined by the charging/discharging characteristics, including the ripple voltage from the charging device, are to be considered.

1.2.2.3 Any special system, e.g. electronic circuits, whose function cannot operate satisfactorily within the limits shown in Table 1.2.2.2 is not to be supplied directly from the system but by alternative means, e.g. through a stabilized supply.

1.2.3 Harmonic content

1.2.3.1 AC electrical equipment is to operate satisfactorily with a supply voltage containing a total harmonic content of the voltage waveform not exceeding 8%. Where the harmonic content may exceed 8%, attention is to be given in selecting the equipment to ensure its normal function.

Section 3 DESIGN, CONSTRUCTION AND INSTALLATION

1.3.1 General requirements

1.3.1.1 Electrical equipment is to be so designed, constructed and installed as to ensure safe operation and facilitate inspection and repair.

1.3.1.2 The distance between live parts of different potential and between live parts and earthed metal, whether across surfaces or in air, is to be adequate for the working voltage, having regard to the nature of the insulating material and the conditions of service.

1.3.1.3 Equipment is not to remain alive through the control circuits or pilot lamps when switched off by the control switch. This does not apply to synchronizing switches and/or plugs.

1.3.1.4 All nuts and screws used for the connection and fastening of electrical equipment are to be provided with means to ensure that they cannot work loose by vibration and shock.

1.3.1.5 The material used to make electrical equipment is to comply with the following requirements:

(1) It is, in general, to be durable, flame-retardant, moisture resistant unless it is adequately protected against the atmospheric environment and temperatures to which it is likely to be exposed.

(2) Insulating materials and insulated windings are to be resistant to moisture, sea air and oil vapour unless special precautions are taken to protect them.

(3) The current carrying parts of electrical equipment are, in general, to be made of copper or copper alloys.

(4) Metal parts of electrical equipment are to be covered with proper protective coating against corrosion unless they are made of satisfactory corrosion-resistant material.

(5) New installation of materials which contain asbestos is to be prohibited.

1.3.1.6 If electrical fittings, not of aluminium, are connected to aluminium, suitable means is to be taken to prevent electrolytic corrosion.

1.3.1.7 All electrical equipment with internal wiring is to be attached with schematic or wiring diagrams in which wiring codes are indicated. All terminals of electrical equipment are to be provided with durable markings or symbols corresponding to those indicated in the diagrams.

1.3.1.8 The controls for emergency alarms are to be marked in red and provided with durable nameplates indicating their purposes.

1.3.1.9 For the fitting of rheostats, starting and charging resistors, heating appliances and other electrical apparatus likely to cause high temperatures, means are to be provided against overheating or igniting of adjacent objects.

1.3.1.10 All electrical equipment is not to be fitted close to the external surfaces of oil compartments, oil tanks or double bottom tanks intended for carrying oils. If this is necessary, electrical equipment is to be

installed at a minimum distance of 50 mm from these surfaces, provided that the electrical apparatuses mentioned in 1.3.1.9 are strictly prohibited to be installed on such surfaces.

1.3.1.11 Generating sets are to be installed with their shafts in parallel with the fore-and-aft direction of the ship, and horizontal motors are also to be installed, as far as practicable, with their shafts in parallel with the fore-and-aft direction of the ship.

1.3.1.12 For the electrical equipment other than that installed in a dedicated compartment, the live parts having a working voltage or a voltage to earth exceeding 50 V are to be so protected that they cannot be inadvertently touched.

1.3.1.13 Where the temperature of the enclosures of the electrical equipment is in excess of 80°C, suitable means are to be provided or suitable arrangement is to be made so as to protect the operators from injurious heating due to inadvertent touching.

1.3.1.14 Holes are not to be drilled in watertight bulkheads, decks or boundary plating of deckhouses for the purpose of fitting the screws used to securing the electrical equipment and cables.

1.3.1.15 Electrical equipment and cables are not to be fitted on the shell plating.

1.3.1.16 Conductors and equipment are to be placed at a suitable distance from the magnetic compass, or are to be so screened that the interfering external magnetic field is negligible.

1.3.2 Protective enclosures

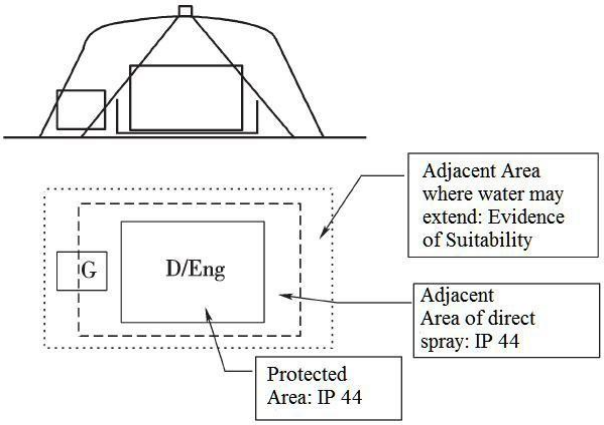
1.3.2.1 The type of protective enclosures for electrical equipment is to comply with IEC Publication 60529: Degrees of Protection Provided by Enclosures (IP Code) or equivalent standards.

1.3.2.2 The type of protective enclosures selected for electrical equipment is to be appropriate to the condition of the location at which such equipment is installed. The lowest degree of protection is to comply with the requirements given in Table 1.3.2.2 unless otherwise specified (e.g. in 1.3.2.3 and 1.3.2.4 of this Section).

Minimum Requirements for the Degree of Protection by Enclosure **Table 1.3.2.2**

(1)	(2)	(3)	(4)							
			Equipment							
Location	Condition of location	Degree of protection	Switchboards, control gear, motor starters	Generators	Motors	Transformers, semiconductor converters	Lighting fixtures	Heating appliances	Cooking appliances	Accessories (e.g. switches, connection boxes)
Dry accommodation spaces	Danger of touching live parts only	IP20	×	–	×	×	×	×	×	×
Dry control rooms			×	–	×	×	×	×	×	×
Control rooms	Danger of dripping water and/or moderate mechanical damage	IP22	×	–	×	×	×	×	×	×
Engine and boiler rooms above floor plates			×	×	×	×	×	×	×	IP44
Steering gear rooms			×	×	×	×	×	×	–	IP44
Refrigerating machinery rooms (excluding ammonia plants)			×	–	×	×	×	×	–	IP44
Emergency machinery rooms			×	×	×	×	×	×	–	IP44
General storage rooms			×	–	×	×	×	×	–	×
Pantries			×	–	×	×	×	×	×	IP44
Provision rooms			×	–	×	×	×	×	–	×
Bathrooms and showers	Increased danger of water and/or mechanical damage	IP34	–	–	–	–	×	IP44	–	IP55
Engine and boiler rooms below floor plates			–	–	IP44	–	×	IP44	–	IP55
Closed fuel oil separator rooms			IP44	–	IP44	–	×	IP44	–	IP55
Closed lube oil separator rooms			IP44	–	IP44	–	×	IP44	–	IP55

(1)	(2)	(3)	(4)							
			Equipment							
Location	Condition of location	Degree of protection	Switchboards, control gear, motor starters	Generators	Motors	Transformers, semiconductor converters	Lighting fixtures	Heating appliances	Cooking appliances	Accessories (e.g. switches, connection boxes)
Ballast pump rooms	Increased danger of water and mechanical damage	IP44	×	–	×	×	IP34	×	–	IP55
Refrigerated rooms			–	–	×	–	IP34	×	–	IP55
Galleys and laundries			×	–	×	×	IP34	×	×	×
Shaft or pipe tunnels in double bottom	Danger of water spraying, presence of cargo dust, serious mechanical damage, aggressive fumes	IP55	×	–	×	×	×	×	–	IP56
Holds for dry cargo			–	–	–	–	×	–	–	×
Open decks	Danger of water ingress in massive quantities	IP56	×	–	×	–	IP55	×	–	×



Notes: ① "×" means that the requirements of column (3) are to be complied with, or if impossible, the requirements of note ② are to be satisfied; "–" means that such equipment is generally not to be installed.

② Where the protection is not achieved by the equipment itself, other means are to be taken or the condition of the location for installing the equipment is to be improved to ensure the degree of protection required in the Table.

③ Where electrical equipment is installed in areas where explosive dusts may be present, the requirements of 1.3.3.7 of this Section are to be complied with.

④ Where the main and emergency switchboards are constructed and installed in accordance with the requirements of Section 3 of Chapter 3 and Sections 1 and 2 of Chapter 2 of this PART respectively, the requirements of this Table may be dispensed with.

1.3.2.3 In the engine room, the electrical and electronic equipment located within areas protected by fixed water-based local fire-fighting systems and those within adjacent areas exposed to direct spray (see Figure 1.3.2.3) are to have a degree of protection not less than IP44, except where evidence of suitability is submitted to and approved by ISC.

G – generator; D/Eng – diesel engine

Figure 1.3.2.3 Areas Protected by Fixed Water-Based Local Application Fire-Fighting Systems

1.3.2.4 In the engine room, the electrical and electronic equipment within adjacent areas where water may extend and which are not covered by 1.3.2.3 above (see Figure 1.3.2.3) may have a lower degree of protection provided evidence of suitability for use in these areas is submitted taking into account the design and equipment layout, e.g. position of inlet ventilation openings, cooling airflow for the equipment is to be assured.

1.3.3 Explosion protection

1.3.3.1 Where electrical equipment is installed in areas where explosive gas or vapour atmospheres may be present, it is to be of a certified safe type complying with the following requirements:

(1) The construction and type testing of the safe type electrical equipment is to be in accordance with the relevant acceptable standards①.

(2) The safe type electrical equipment is to be certified by a competent testing authority approved by ISC.

1.3.3.2 The certified safe type equipment normally used on board ships includes the following types of protection:

(1) Intrinsically safe Ex “i”;
(2) Flameproof Ex “d”;
(3) Increased safety Ex “e”;
(4) Pressurized enclosure Ex “p”;
(5) Special protection Ex “s”;
(6) Powder filled Ex “q”;
(7) Encapsulated Ex “m”.

1.3.3.3 The electrical equipment allowed to be fitted in spaces subject to an explosion hazard, e.g. battery rooms, lamp stores and paint lockers (including ventilation ducts), is to comply with the following requirements:

(1) The electrical equipment is to be installed in paint stores and in ventilation ducts serving such spaces only when it is essential for operational services. Such equipment is to be of a certified safe type listed in 1.3.3.2(1) to (5) of this Section. For other spaces, the electrical equipment of certified safe types listed in 1.3.3.2 of this Section may be fitted, and the explosion groups and temperature classes of such equipment are at least to comply with the requirements in Table 1.3.3.3.

(2) Cables (through runs or terminating cables) of armoured type or installed in metallic conduits are to be used.

(3) The switches, protective devices and motor control gear for the electrical equipment installed in such spaces are to interrupt all poles or phases and preferably are to be located in non-hazardous spaces.

In addition, the relevant requirements for paint locker ventilation openings, battery rooms, oil tankers and ships carrying vehicles with fuel in their tanks for their own propulsion are given in 1.3.3.4, 1.3.3.5 of this Section, and Sections 11, 16 and 17 of Chapter 2.

---

① Refer to IEC publication 60079: Electrical Apparatus for Explosive Gas Atmospheres, or an equivalent national standard. e.g., GB 3836: Electrical Apparatus for Explosive Gas Atmospheres.

Explosion Group and Temperature Class **Table 1.3.3.3**

Location	Group①	Temperature class①
Battery rooms	II C②	T1
Paint lockers	II B	T3
Lamp stores	II A	T3
Ammonia plant rooms③	II A	T1
Acetylene storage rooms	II C	T2
Spaces carrying dangerous goods	According to the category of dangerous goods carried	According to the category of dangerous goods carried
Tunnels for pipes containing oil with a flash point of 60℃ or below	II A	T3

Notes: ① The explosion groups and temperature classes of electrical equipment listed in this Table and hereinafter in this PART are according to the relevant requirements of IEC Publication 60079: Electrical Apparatus for Explosive Gas Atmospheres or of GB 3836: Electrical Apparatus for Explosive Atmospheres.

② Explosion groups II A, II B and II C of electrical equipment listed in this PART are applicable only to intrinsically safe apparatus and flame-proof apparatus. For other types of explosion-proof electrical equipment, Group II is to be used.

③ Electrical equipment installed in R717 refrigerator room is to comply with the requirements in Section 5 of Chapter 2 of PART FIVE of the Rules.

1.3.3.4 In the areas on open deck within 1 m of inlet and exhaust ventilation openings or within 3 m of exhaust mechanical ventilation outlets of the paint locker, the following electrical equipment may be installed:
(1) certified safe type equipment listed in 1.3.3.2(1) to (5) of this Section, while cables and their installation are to comply with the requirements of 1.3.3.3(2);
(2) explosion-proof equipment of non-sparking construction (Ex "n");
(3) appliances which do not generate arcs in service and whose surface does not reach unacceptably high temperature;
(4) appliances with simplified pressurized enclosures or vapour-proof enclosures (minimum degree of protection IP55) whose surface does not reach unacceptably high temperature.

1.3.3.5 The enclosed spaces giving access to the paint locker may be considered as non-hazardous, provided that:
(1) the door to the paint locker or the door of the paint locker is a gastight door with self-closing devices (a watertight door may be regarded as a gastight door) without holding back arrangements;
(2) the paint locker is provided with an acceptable, independent, natural ventilation system ventilated from a safe area;
(3) warning notices are fitted adjacent to the paint locker entrance stating that the locker contains flammable liquids.

1.3.3.6 Socket outlets are, unless expressly specified otherwise, not to be installed in spaces subject to an explosion hazard.

1.3.3.7 Where electrical equipment is to be installed in areas where explosive dusts may be deposited, it is to comply with the following requirements:
(1) the degree of protection by enclosures is to be at least IP55;
(2) the maximum surface temperature of the equipment in continuous service is to be at least 75 K lower than the glow temperature of a 5 mm thick layer of the dust.

1.3.4 Earthing

1.3.4.1 All accessible metal parts of the electrical equipment, other than current-carrying ones, are to be earthed, except for:
(1) lamp caps;
(2) shades, reflectors and guards supported on lamp holders or lighting fittings constructed of, or shrouded in, non-conducting material;
(3) metal parts on, or screws in or through, non-conducting material, which are separated by such material from current-carrying parts and from earthed non-current-carrying parts in such a way that in normal use they cannot become live or come into contact with earthed parts;
(4) portable appliances having double and/or reinforced insulation, provided that the appliances conform with recognized safety requirements;
(5) bearing housings which are insulated in order to prevent circulation of current in the bearings;
(6) clips for fluorescent lamps;
(7) apparatus supplied at a working voltage not more than 50 V. For the alternating current, this voltage is a

value of root mean square. Autotransformers are not to be used for the purpose of achieving this voltage;
(8) cable clips.

1.3.4.2 When the electrical equipment is directly fixed on the metal hull of the ship or securely fixed on bedplates (or supports) which have a good electrical contact with the metal hull of the ship, a special earthing conductor may not be required.

1.3.4.3 Whether the earthing is achieved through a special conductor or by bedplates (or supports) of the equipment, the surfaces in contact are to be clean, flat and bright so as to ensure an effective contact, and measures are to be taken to prevent the connection from loosening and corrosion.

1.3.4.4 When special earthing conductors are used, they are to be of copper or other corrosion-resistant materials of good conductivity, and are to be protected against mechanical damage and corrosion where necessary. The nominal cross-sectional area of various copper earthing conductors is not to be less than required in Table 1.3.4.4.

1.3.4.5 Bare metal parts of movable or portable appliances, other than current-carrying ones, are to be earthed by means of an earth-continuity conductor in the flexible cable or cord through the associated plug and socket outlet, and the cross-sectional area of the earth conductor is to comply with the requirements of Table 1.3.4.4.

Size of Earthing Conductors **Table 1.3.4.4**

Type of earthing conductor	Cross-sectional area of associated current-carrying conductor S (mm^2)	Minimum cross-sectional area of copper earthing conductor Q (mm^2)
Earth-continuity conductor in flexible cable or flexible cord	$S \leq 16$	$Q = S$
	$S > 16$	$Q = S/2$, but at least 16
Earth-continuity conductor incorporated in fixed cable	$S \leq 16$	$Q = S$, but at least 1.5
	$S > 16$	$Q = S/2$, but at least 16
Special fixed earthing conductor	$S \leq 2.5$	$Q = S$, but at least 1.5
	$2.5 < S \leq 120$	$Q = S/2$, but at least 4
	$S > 120$	$Q = 70$

1.3.4.6 Metal coverings (braid or armour) of cables are to be effectively earthed at both ends of the run, except that final sub-circuits may be earthed at the supply end only. This does not necessarily apply to control and instrumentation cables or intrinsically safe circuit cables where single point earthing is permitted for technical or safety reasons.

1.3.4.7 The metal coverings of cables may be earthed by one of the means described below:
(1) gripped by metal clamps and connected to the metal hull of the ship by dedicated copper earthing conductors. The relationship between the cross-sectional area Q of the copper earthing conductors and the cross-sectional area S of the current-carrying conductors of the cables is to comply with Table 2 in IEC 60092-352 or as follows:

$Q \geq 1.5$ mm^2, for $S \leq 25$ mm^2;
$Q \geq 4$ mm^2, for $S > 25$ mm^2;

(2) by means of glands intended for this purpose and so designed as to ensure an effective earth connection;
(3) by means of clamps or clips of corrosion-resistant metal, enabling a good contact between the metal coverings of cables and the earthed metal.

1.3.4.8 The electrical continuity of metal coverings of cables is to be ensured throughout the length of the cables, particularly at joints and tappings.

1.3.4.9 Every connection of an earth-continuity conductor or a special earthing conductor to the hull structure is to be made in an accessible position, and is to be secured by a screw of brass or other corrosion-resistant material and having a diameter not less than 4 mm, which is to be used for this purpose only.

1.3.4.10 Where aluminium superstructures are secured to the steel hull of a ship with an insulation to prevent electrolytic corrosion between these materials, a separate bonding connection is to be provided between the superstructure and the hull which is to be made in such a manner that electrolytic corrosion is prevented and the connection points may readily be inspected.

1.3.4.11 In order to avoid the hazard of an incentive discharge due to the build-up of static electricity resulting from the flow of liquids/gases/vapours, all cargo tanks, process plants and piping systems that contain flammable liquids, evolve combustible gases and/or develop flammable dusts are to comply with the following requirements:
(1) The resistance between the above cargo tanks, process plants and piping systems and the hull of the ship is not to be greater than 1 MΩ.
(2) The requirements of 1.3.4.11(1) will be readily met without the use of bonding straps where cargo tanks,

process plants and piping systems are directly or via their supports, either welded or bolted to the hull of the ship.

(3) Bonding straps are required for cargo tanks, process plants and piping systems which are not permanently connected to the hull of the ship, e.g.:

① independent cargo tanks;

② cargo tanks and piping systems which are electrically separated from the hull of the ship;

③ pipe connections arranged for the removal of spool pieces;

④ wafer-style valves with non-conductive (e.g. PTFE) gaskets or seals.

(4) Where bonding straps are required, they are to be:

① clearly visible so that any shortcomings can be clearly detected;

② designed and sited so that they are protected against mechanical damage and that they are not affected by high resistivity contamination, e.g. corrosive products or paint;

③ easy to install and replace.

(5) Bonding straps are to be made of copper or other corrosion-resistant materials of good conductivity, having a cross-sectional area of at least 10 mm^2.

1.3.5 Electromagnetic compatibility

1.3.5.1 Appropriate measures are to be taken to reduce the interference due to electromagnetic energy so that all electrical and electronic equipment can operate normally in a ship's electromagnetic environment.

1.3.5.2 The allowable value of the voltage (current) of the interference induced by electrical and electronic equipment and the means of interference suppression are to comply with the relevant provisions of acceptable standards①.

1.3.6 Visual and audible signals

1.3.6.1 Except those required in 1.3.6.2 of this Section, the colour of visual signals is to comply with the requirements of Table 1.3.6.1.

1.3.6.2 Except those required above, the visual and audible signals are to comply with the acceptable standards②.

Colours of Visual signals **Table 1.3.6.1**

Colour	Meaning	Explanation	Example
Red	Danger or alarm	Warning of danger or a situation which requires immediate action	Operation failure of essential services; Temperature or pressure of water, oil etc. reaching a critical value; Power failure of essential circuits
Yellow	Caution	Change or impending change of conditions	Temperature or pressure is abnormal, but not reaching a critical value
Green	Safety (normal operating or normal working conditions)	Indication of a safe situation	Normal operation of machinery; Normal circulation of liquids; Pressure, temperature and currents within limits
Blue	Instruction/information (specific meaning assigned according to the need in the case considered)	Blue may be given a meaning which is not covered by the three above colours: red, yellow and green	Motor begins to start; Unloading generator begins to switch on; Heating circuit of stopping motor is connected
White	No specific meaning assigned	Any meaning, used if red, yellow or green is considered not applicable	Earthing insulation indication; Synchronizing lamp; Telephone calling; Automated equipment

1.3.7 Harmonic Distortion for Ship Electrical Distribution System including Harmonic Filters③

1.3.7.1 Ships where harmonic filters are installed on main busbars of electrical distribution system are to meet the requirements of 1.3.7.2 to 1.3.7.6 below. However, harmonic filters installed for single application frequency drives such as pump motors and harmonic filters installed for enhancing electromagnetic compatibility of single equipment/system may be excluded from these requirements.

1.3.7.2 The total harmonic distortion (THD) of electrical distribution systems is not to exceed 8%. This

---

① Refer to IEC Publication 60533: Electromagnetic Compatibility of Electrical and Electronic Installations in Ships, or corresponding standards.

② Refer to Code on Alerts and Indicators, 2009 adopted by IMO resolution A.1021(26).

③ Applicable to new ships and ships where an application for a periodical or occasional machinery survey after the retrofit of harmonic filters is dated on or after 1 July 2017.

limit may be exceeded where all installed equipment and systems have been designed for a higher specified limit and the harmonic distortion calculation report is to be provided and made available on board as a reference for the surveyor at each periodical survey.

1.3.7.3 Ships are to be fitted with facilities to continuously monitor the levels of harmonic distortion experienced on the main busbar as well as alerting the crew should the level of harmonic distortion exceed the acceptable limits. Where the engine room is provided with automation systems, this reading is to be logged electronically, otherwise it is to be recorded in the engine log book for future inspection by the surveyor.

1.3.7.4 The system integrator of the distribution system is to show, by calculation, the effect of a failure of a harmonic filter on the level of harmonic distortion experienced. The system integrator of the distribution system is to provide the ship owner with guidance documenting permitted modes of operation of the electrical distribution system while maintaining harmonic distortion levels within acceptable limits during normal operation as well as following the failure of any combination of harmonic filters. The calculation results and validity of the guidance provided are to be verified by the surveyor during sea trials.

1.3.7.5 A harmonic filter is to be arranged as a three-phase unit with individual protection of each phase. The activation of the protection arrangement in a single phase is to result in automatic disconnection of the complete filter. Additionally, a current unbalance detection system independent of the overcurrent protection alerting the crew in case of current unbalance is to be installed. This alarm is to be provided locally and/or in normally attended spaces.

1.3.7.6 Consideration is to be given to additional protection for the individual capacitor element (e.g. relief valve or overpressure disconnector) in order to protect against damage from rupturing. This consideration is to take into account the type of capacitors used.

CHAPTER 2 ELECTRICAL INSTALLATIONS IN SHIPS

Section 1 MAIN SOURCE OF ELECTRICAL POWER

2.1.1 Generating sets

2.1.1.1 A main source of electrical power having sufficient capacity to supply all services mentioned in 1.1.1.5(1) of this PART is to be provided, and the following requirements are to be complied with.

(1) The main source of electrical power is to consist of at least two generating sets.

(2) The number and ratings of these generating sets are to be such that in the event of any one generating set being stopped it will still be possible to supply those services necessary to provide normal operational conditions of propulsion and safety of the ship and essential for ships with class notation for carrying refrigerated cargoes as specified in PART FIVE of the Rules. Furthermore, minimum comfortable conditions of habitability are also to be ensured, which include at least adequate services for cooking, heating, domestic refrigeration, mechanical ventilation, sanitary and fresh water.

(3) The generating sets are to be such as to ensure that with any one generator or its prime mover out of operation, the remaining generating sets are still capable of providing the electric services necessary to start the main propulsion plant from a dead ship condition.

(4) Where the main source of electrical power is necessary for propulsion and steering of the ship, the continuity of the power supply to the equipment necessary for the propulsion and steering and for ensuring the safety of the ship is to comply with the following requirements:

① Where the electrical power is normally supplied by more than one generating set simultaneously in parallel operation, means of protection, including automatic shedding (see 2.5.7.1 of this Chapter) of non-essential services and if necessary, automatic shedding of the arrangements for habitability and secondary essential services, are to be provided to ensure that in case of loss of any of these generating sets, the remaining ones are kept in operation to supply equipment necessary for propulsion and steering and for ensuring the safety of the ship.

② Where the electrical power is normally supplied by one generator, provision is to be made, upon loss of power, for automatic starting and connecting to the main switchboard of a stand-by generator(s) of sufficient capacity with automatic restarting of the essential auxiliaries, in sequential operation if required. Starting and connection to the main switchboard of the stand-by generator is to be as rapid as possible, preferably within 30 s, but in any case not more than 45 s, after loss of power.

(5) Where the main source of electrical power is necessary for propulsion of the ship, the main bus-bar is to be subdivided into at least two independent sections which are normally be connected by a circuit breaker without tripping mechanism or disconnecting link or switch by which the bus-bar can be split easily. So far as is practicable, the connection of generating sets and other duplicated equipment is to be equally divided between the sections.

(6) A common power plant may be provided as both the main source of electrical power and the electrical power for propulsion, and in this case the requirements of 15.2.1.9 of Chapter 15, PART EIGHT of the Rules are to be complied with.

2.1.1.2 The alternating current system is to be such that with one generating set out of action, the remaining sets have sufficient reserve capacity to permit the starting of the largest motor without causing any motor to stall or any other device to fail due to excessive voltage drop on the system. Motors which have a very large capacity and are not essential to the safe navigation of the ship, such as thruster motors, may be started when all generators are put into operation without causing any essential services to stop.

2.1.1.3 The arrangement of the ship's main source of electrical power is to be such that the operation of the services referred to in 1.1.1.5(1) of this PART can be maintained regardless of the speed and direction of the propulsion machinery shafting.

2.1.1.4 For calculation of the capacity of generating sets, where the detailed power of refrigerated containers can not be provided, it is recommended that 11 kW be taken for each socket where the sockets of refrigerated containers are adaptable to power supply for 20 ft or 40 ft containers. It is also recommended that 7.5 kW be taken for each socket suitable only for power supply of 20 ft containers. A diversity factor of 0.6 may be taken for calculation of loading of containers.

2.1.1.5 A main source of electrical power may be provided as necessary for non-self-propelled ships. Where the main source of electrical power is the generator, the provisions of 2.1.1.1 to 2.1.1.3 of this Chapter need not be complied with.

2.1.2 Generators driven by main propulsion machinery (e.g. shaft-driven generators)

2.1.2.1 A generator driven by the ship's main propulsion machinery may be considered part of the ship's main source of electrical power, provided that:
(1) the generator is capable of operating normally under all weather conditions during sailing or maneuvering, also when the vessel is stopped, within the specified limits for the voltage variation in paragraphs 3.2.7 and 3.2.8 and for the frequency variation in 1.2.2.2;
(2) the rated capacity of the generator is in compliance with 2.1.1.1(2) upon loss of any other generator in service;
(3) the short circuit current of the generator and/or generator system is sufficient to trip the generator circuit breaker, taking into account the selectivity of the protective devices for the distribution system. Protection is to be arranged in order to safeguard the generator in case of a short circuit in the main bus-bar. The generator is to be suitable for further use after fault clearance;
(4) the automatic start of standby sets is in compliance with 2.1.1.1(4)②.
2.1.2.2 A generators and/or generating system driven by the ship's propulsion machinery and not forming part of the ship's main source of electrical power may be used, whilst the ship is at sea, to supply the electrical equipment necessary for normal operational and habitable conditions provided that:
(1) sufficient and adequately rated additional generators are fitted, which constitute part of the main source of electrical power required by 2.1.1.1 of this Section;
(2) arrangements are fitted to automatically start at least one of the generators, which constitute part of the main source of electrical power required by 2.1.1.1 of this Section, in compliance with 2.1.1.1(4)②, when frequency variations exceed the limits specified below:
Frequency variations (permanent): ±5.5%
Frequency variations (transient): ±11% (5 s);
(3) voltage variations are within the limits specified in 3.2.7 and 3.2.8 and frequency variations within the limits specified in 1.2.2.2;
(4) the short circuit current of the generator and/or generating system is sufficient to trip the generator and/or generating system circuit breaker, taking into account the selectivity of the protective devices for the distribution system;
(5) automatic load shedding arrangements are fitted in accordance with the requirements of 2.5.7 of this Chapter;
(6) on ships having remote control of the propulsion machinery from the navigation bridge, means are provided or procedures are in place to ensure that the power supply to essential services is maintained during maneuvering conditions in order to avoid a blackout situation.

2.1.3 Transformers

2.1.3.1 The number, capacity and arrangement of transformers are to meet the following requirements if they constitute the necessary parts of lighting system and main electric power source system as required in 2.1.1.1 of this Section.
(1) The transformers are to be such that, with any one transformer out of operation, the remaining transformers are sufficient to ensure the safe operation of the equipment necessary for normal propulsion and for safety of the ship. Furthermore, minimum comfortable conditions of habitability are also to be ensured, which include at least adequate services for cooking, heating, domestic refrigeration, mechanical ventilation, sanitary and fresh water.
(2) Each transformer is to be located as a separate unit with separate enclosure or equivalent, and is to be served by separate circuits on the primary and secondary sides.
(3) Each primary circuit is to be provided with switch gear and protection devices in each phase.
(4) Each of the secondary circuits is to be provided with a multi-pole isolating switch.

2.1.4 Installation of switchboards

2.1.4.1 The main switchboard is to be so placed relative to the main power plant that, as far as is practicable, the integrity of the normal electrical supply will be affected only by a fire or other casualty in one space. An environmental enclosure for the main switchboard, such as may be provided by a machinery control room situated within the main boundaries of the space, is not to be considered as separating the switchboard from the generators.
2.1.4.2 Water, oil or steam pipes, oil tanks or other liquid containers are not to be installed above or behind the switchboard. If this is unavoidable, suitable protection is to be provided in these positions.
2.1.4.3 Passages of an adequate width are to be left in front of and behind switchboards. The width of the front passage is to be at least 0.8 m. The width of passage behind the switch gear is to be at least 0.6 m, and at least 0.5 m at frames. If the construction of a switchboard is such as to permit maintenance, inspection and replacement of parts from the front or from the ends, the passageway behind the switchboard may be

dispensed with.
2.1.4.4 Where the length of the main switchboard is greater than 4 m, passageways are to be, as far as possible, provided at both ends of the switchboard. Except that the main switchboard is installed in the machinery control room, doors with locking devices are to be provided at both ends of the passageway behind the switchboard.
2.1.4.5 The passageways in front of and behind the main switchboard are to be covered by non-slipping and oil-proof insulating mats or insulated wood gratings.

2.1.5 Automatic connecting and disconnecting of main generating set

2.1.5.1 Requirements of paragraph 2.1.5.2 to 2.1.5.6 are to be met where start, stop and load sharing between generators, is controlled by an automation system.
2.1.5.2 The following alarms are to be arranged:
(1) variations in bus bar voltage from the rated value (high and low);
(2) variations in bus bar frequency from the rated value (high and low);
(3) automatic load shedding;
(4) failure in automatic switch-on of circuit breaker of generator;
(5) automatic tripping of circuit breaker of generator;
(6) failure in load distribution (with the necessary time delay, see paragraph 3.2.8.5 of Chapter 3 for the percentage of load distribution).
2.1.5.3 Means are to be provided to avoid two or more than two generating sets being switched on the common bus-bar of main switchboard simultaneously.
2.1.5.4 After a blackout due to short circuit, the generator circuit breaker is permitted to be switched on only once.
2.1.5.5 Where the standby generating set has been started as a result of a prolonged main bus-bar voltage or frequency fluctuation, the running generating set is to be stopped and disconnected from the switchboard prior to connection of the standby generating set.
2.1.5.6 Automatic starting attempts which fail are to be limited to restrict consumption of starting energy.

Section 2 EMERGENCY SOURCE OF ELECTRICAL POWER

2.2.1 General requirements

2.2.1.1 All passenger ships and cargo ships of more than 500 gross tonnage are to be provided with a self-contained emergency source of electrical power.
2.2.1.2 The emergency source of electrical power is to be so arranged as to comply with the following:
(1) The emergency source of electrical power, associated transforming equipment (if any), transitional source of emergency power, emergency switchboard and emergency lighting switchboard are to be located above the uppermost continuous deck and are to be readily accessible from the weather deck. They are not to be located forward of the collision bulkhead, except where permitted by ISC for cargo ships in exceptional circumstance.
(2) The location of the emergency source of electrical power, associated transforming equipment (if any), the transitional source of emergency power, the emergency switchboard and the emergency lighting switchboard in relation to the main source of electrical power, associated transforming equipment (if any), and the main switchboard is to be such as to ensure that a fire or other casualty in spaces containing the main source of electrical power, associated transforming equipment (if any), and the main switchboard or in any machinery space of category A will not interfere with the supply, control and distribution of emergency electrical power. As far as practicable, the space containing the emergency source of electrical power, associated transforming equipment (if any), the transitional source of emergency electrical power and the emergency switchboard is not to be continuous to the boundaries of machinery spaces of category A or those spaces containing the main source of electrical power, associated transforming equipment (if any), or the main switchboard.
2.2.1.3 The emergency source of electrical power may be a generator, which is to comply with the following requirements:
(1) driven by a suitable prime mover with independent cooling system and supply of fuel as well as starting arrangements complying with the requirements of 9.5.3 of Chapter 9, PART THREE of the Rules;
(2) started automatically upon failure of the electrical supply from the main source of electrical power and connected automatically to the emergency switchboard, and those services referred to in 2.2.2.2 (for passenger ships) or 2.2.3.2 (for cargo ships) of this Section then transferred automatically to the emergency generating set, except for cargo ships fitted with a transitional source of emergency electrical power in

accordance with 2.2.1.5 of this Section. The automatic starting system and the characteristics of the prime mover are to be such as to permit the emergency generator to carry its full rated load as quickly as is safe and practicable, subject to a maximum of 45 s.

2.2.1.4 The emergency source of electrical power may also be an accumulator battery, which is to comply with the following requirements:

(1) carrying the emergency electrical load without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage;

(2) automatically connecting to the emergency switchboard in the event of failure of the main source of electrical power; and

(3) supplying those services (except as otherwise stated) referred to in 2.2.2.1 (for passenger ships) or 2.2.3.1 (for cargo ships) of this Section, and immediately supplying those services referred to in 2.2.2.2 (for passenger ships) or 2.2.3.2 (for cargo ships) of this Section.

2.2.1.5 Where the emergency source of electrical power is a generator, a transitional source of emergency electrical power which consists of an accumulator battery is to be provided in compliance with the following requirements, except for cargo ships fitted with an emergency generator capable of automatic starting in accordance with 2.2.1.3(2):

(1) carrying the emergency electrical load without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage;

(2) so arranged as to supply immediately and automatically in the event of failure of either the main or emergency source of electrical power those services referred to in 2.2.2.2 (for passenger ships) or 2.2.3.2 (for cargo ships) of this Section.

2.2.1.6 Where the emergency source of electrical power is required to restore propulsion from a dead ship condition, the capacity is to be sufficient to supply the following equipment within 30 min of the blackout (For steam turbine ships, the 30-min time limit is to be taken as the time from blackout/dead ship condition to light-off of the first boiler):

(1) equipment referred to in 2.2.2.1(1), (2) and (3) or in 2.2.3.1 (1), (2), (3) and (4) of this Section;

(2) restoring propulsion of the ship and operation of other machineries (as appropriate) from a dead ship condition.

2.2.1.7 The emergency switchboard is to be installed as near as is practicable to the emergency source of electrical power and to comply with the following requirements:

(1) Where the emergency source of electrical power is a generator, the emergency switchboard is to be located in the same space unless the operation of the emergency switchboard would thereby be impaired.

(2) Where the emergency source of electrical power is an accumulator battery, the accumulator battery is not to be installed in the same space as the emergency switchboard.

(3) Water, oil or steam pipes, oil tanks or other liquid containers are not to be installed above or behind the emergency switchboard. If this is unavoidable, suitable protection is to be provided in these positions.

(4) The passageways in front of the emergency switchboard are to be covered by non-slipping and oil-proof insulating mats or insulated wood gratings.

2.2.1.8 An indicator is to be mounted in a suitable place on the main switchboard or in the machinery control room to indicate when the batteries constituting either the emergency source of electrical power or transitional source of emergency electrical power are being discharged.

2.2.1.9 The emergency switchboard is to be supplied during normal operation from the main switchboard by an interconnector feeder which is to be protected according to the requirements of 2.5.9.6 and which is to be disconnected automatically at the emergency switchboard upon failure of the main source of electrical power.

2.2.1.10 In order to ensure ready availability of the emergency source of electrical power, arrangements are to be made, where necessary, to disconnect automatically non-emergency circuits from the emergency switchboard to ensure that electrical power is to be available to the emergency circuits.

2.2.1.11 Provided that suitable measures are taken for safeguarding independent emergency operation under all circumstances, the emergency generator may be used exceptionally, and for short periods, to supply non-emergency circuits.

2.2.1.12 Where the emergency and/or transient emergency source of electrical power is an accumulator battery which supplies emergency loads via an electronic converter or inverter, the maximum permitted D.C voltage variations (taken as those on the load side of the converter or inverter) are to be within 12% above or below its nominal voltage; where DC is converted into AC the maximum variations are to comply with Table 1.2.2.2.

2.2.1.13 UPS units utilizing valve regulated sealed batteries, as described in 2.2.2.1 and 2.2.3.1 of this Section, may be located in compartments with normal electrical equipment, provided the ventilation arrangements are in accordance with the requirements of IEC 62040-1, IEC 62040-2, IEC 62040-3, IEC

62040-4 and/or IEC62040-5-3 publication (where applicable) or an acceptable standard.

2.2.2 Scope and period of supply of the emergency source in passenger ships

2.2.2.1 The electrical power available is to be sufficient to supply all those services that are essential for safety in an emergency, due regard being paid to such services as may have to be operated simultaneously. The emergency source of electrical power is to be capable, having regard to starting currents and the transitory nature of certain loads, of supplying simultaneously at least the following services for the periods specified hereinafter, if they depend upon an electrical source for their operation:

(1) for a period of 36 h, emergency lighting:

① at every muster and embarkation station and over the sides as required in the SOLAS Convention in force;

② in alleyways, stairways and exits giving access to the muster and embarkation stations as required in the SOLAS Convention in force;

③ in all escape routes with their stairways and exits (including angles and intersections) placed not more than 0.3 m above the deck as required in the SOLAS Convention in force (where an emergency source of electrical power is required for the supply);

④ in all service and accommodation alleyways, stairways and exits, personnel lift cars;

⑤ in public spaces and in cabins accommodating more than 16 persons;

⑥ in the machinery spaces and main generating stations including their control positions;

⑦ in all control stations, machinery control rooms, and at each main and emergency switchboard;

⑧ at all stowage positions for firemen's outfits;

⑨ at the steering gear; and

⑩ at the fire pump, the sprinkler pump and the emergency bilge pump referred to in the subparagraph (4) and at the starting position of their motors;

(2) for a period of 36 h:

① the navigation lights and other signal lights required in the International Regulations for Preventing Collisions at Sea in force;

② VHF radio equipment, MF radio installation (if any), ship earth station (if any) and MF/HF radio equipment (if any) required in the SOLAS Convention in force;

(3) for a period of 36 h:

① all internal communication equipment required in an emergency;

② the navigational aids as required in the SOLAS Convention in force, where such provision is unreasonable or impracticable, this requirement may be waived for ships of less than 5,000 gross tonnage, subject to agreement of ISC;

③ the fire detection and fire alarm system, and the fire door holding and release system; and

④ for intermittent operation of the daylight signaling lamp, the ship's whistle, the manually operated call points and all internal signals that are required in an emergency (e.g. general emergency alarm system, alarms for warning of the release of extinguishing media),

unless such services mentioned above in ① to ④ have an independent supply for the period of 36 h from an accumulator battery or have an uninterruptible power system (UPS) complying with the requirements of Section 9, Chapter 3 of this PART suitably located for use in an emergency;

(4) for a period of 36 h:

① one of the fire pumps required in the SOLAS Convention in force;

② the automatic sprinkler pump, if any;

③ the emergency bilge pump and all the equipment essential for the operation of electrically powered remote controlled bilge valves;

(5) for the period of time required in 13.1.8 of PART THREE of the Rules, the steering gear if required to be so supplied by that paragraph;

(6) for a period of half an hour:

① any watertight doors required in the SOLAS Convention in force to be power operated together with their indicators and warning signals;

② the emergency arrangements to bring the lift cars to deck level for the escape of persons. The passenger lift cars may be brought to deck level sequentially in an emergency;

2.2.2.2 The transitional source of emergency electrical power required in 2.2.1.5 of this Section is to be of sufficient capacity to supply at least the following services, if they depend upon an electrical source for their operation:

(1) for half an hour:

① the lighting required in 2.2.2.1(1) (except for 2.2.2.1(1)③) and navigation lights and other signal lights required in 2.2.2.1(2)① of this Section;

② all services required in 2.2.2.1 (3)①, ③ and ④ unless such services have an independent supply for the period specified from an accumulator battery suitably located for use in an emergency;

(2) power to operate the watertight doors, but not necessarily all of them simultaneously, unless an independent temporary source of stored energy is provided;

(3) power to the control, indication and alarm circuits for operation of watertight doors for half an hour.

2.2.2.3 In addition to the emergency lighting required above, passenger ships with ro-ro cargo spaces or special category spaces are to be provided with the following:

(1) all passenger public spaces and alleyways are to be provided with supplementary emergency lighting complying with the following:

① capable of operating for at least three hours when all other sources of electrical power have failed and under any condition of heel;

② the illumination provided is to be such that the approach to the means of escape can be readily seen;

③ the source of power for the supplementary lighting is to consist of accumulator batteries located within the lighting units that are continuously charged, where practicable, from the emergency switchboard. Alternatively, other means of lighting which is at least as effective may be accepted by ISC;

④ the supplementary lighting is to be such that any failure of the lamp will be immediately apparent;

⑤ any accumulator battery provided is to be replaced at intervals having regard to the specified service life in the ambient conditions that they are subject to in service;

(2) a portable rechargeable battery operated lamp is to be provided in every crew space alleyway, recreational space and every working space which is normally occupied unless supplementary emergency lighting, as required in (1) above, is provided.

2.2.3 Scope and period of supply of the emergency source in cargo ships

2.2.3.1 The electrical power available is to be sufficient to supply all those services that are essential for safety in an emergency, due regard being paid to such services as may have to be operated simultaneously. The emergency source of electrical power is to be capable, having regard to starting currents and the transitory nature of certain loads, of supplying simultaneously at least the following services for the periods specified hereinafter, if they depend upon an electrical source for their operation:

(1) for a period of 3 h, emergency lighting at every muster and embarkation station and over the sides as required in the SOLAS Convention in force;

(2) for a period of 18 h, emergency lighting:

① in all services and accommodation alleyways, stairways and exits, personnel lift cars and personnel lift trunks;

② in the machinery spaces and main generating stations including their control positions;

③ in all control stations, machinery control rooms, and at each main and emergency switchboard;

④ at all stowage positions for firemen's outfits;

⑤ at the steering gear;

⑥ at the fire pump referred to in (5), at the sprinkler pump (if any), and at the emergency bilge pump (if any), and at the starting positions of their motors;

⑦ in all cargo pump rooms of tankers;

(3) for a period of 18 h:

① the navigation lights and other signal lights required in the International Regulations for Preventing Collisions at Sea in force;

② VHF radio installation, MF radio installation (if any), ship earth station (if any) and MF/HF radio installation (if any) required in the SOLAS Convention in force;

(4) for a period of 18 h:

① all internal communication equipment as required in an emergency;

② the navigational aids as required in the SOLAS Convention in force, where such provision is unreasonable or impracticable, this requirement may be waived for ships of less than 5,000 gross tonnage, subject to agreement of ISC;

③ the fire detection and fire alarm system;

④ intermittent operation of the daylight signaling lamp, the ships whistle, the manually operated call

points and all internal signals that are required in an emergency (e.g. general emergency alarms system, alarms for warning of the release of extinguishing media, etc.),

unless such services mentioned above in ① to ④ have an independent supply for the period of 18 h from an accumulator battery or have an uninterruptible power system (UPS) complying with the requirements of Section 9, Chapter 3 of this PART suitably located for use in an emergency;

(5) for a period of 18 h, one of the fire pumps required in the SOLAS Convention in force if dependent upon the emergency generator for its source of power;

(6) for the period of time required in 13.1.8 of PART THREE of the Rules, the steering gear where it is required to be so supplied by that paragraph;

2.2.3.2 The transitional source of emergency electrical power required in 2.2.1.5 of this Section is to be of sufficient capacity to supply at least the following services for half an hour, if they depend upon an electrical source for their operation:

(1) the lighting required in 2.2.3.1(1) and (2), and navigation lights and other signal lights required in 2.2.3.1(3)①. For this transitional phase, the required emergency electric lighting, in respect of the machinery space and accommodation and service spaces may be provided by permanently fixed, individual, automatically charged, relay operated accumulator lamps; and

(2) all services required in 2.2.3.1(4)①, ③ and ④, unless such services have an independent supply for the period specified from an accumulator battery suitably located for use in an emergency.

2.2.4 Use of emergency generator in port

2.2.4.1 The emergency generator may be used during lay time in port for the supply of the ship mains, provided the requirements below are complied with:

(1) to prevent the generator or its prime mover from becoming overloaded when used in port, arrangements are to be provided to shed sufficient non-emergency loads to ensure its continued safe operation;

(2) the prime mover is to be fitted with fuel oil filters and lubrication oil filters, monitoring equipment and protection devices as required for the prime mover for main power generation and for unattended operation;

(3) the fuel oil supply tank to the prime mover is to be provided with a low level alarm, arranged at a level ensuring sufficient fuel oil capacity for the emergency services for the period of time as required in 2.2.2 or 2.2.3 of this Section;

(4) the prime mover is to be designed and built for continuous operation and to be subjected to a planned maintenance scheme verified by ISC ensuring that it is always available and capable of fulfilling its role in the event of an emergency at sea;

(5) fire detectors are to be installed in the location where the emergency generator set and emergency switchboard are installed;

(6) means are to be provided to readily change over to emergency operation;

(7) control, monitoring and supply circuits, for the purpose of the use of the emergency generator in port, are to be so arranged and protected that any electrical fault will not influence the operation of the main and emergency services. When necessary for safe operation, the emergency switchboard is to be fitted with switches to isolate the circuits;

(8) instructions, which are to contain information on required fuel oil tank level, position of harbor/sea mode switch, ventilation openings etc., are to be provided on board to ensure that when the vessel is under way all control devices (e.g. valves, switches) are in a correct position for the independent emergency operation of the emergency generator set and emergency switchboard. These instructions are to be posted in the emergency generator room.

Section 3 EXTERNAL SOURCE OF ELECTRICAL POWER

2.3.1 Shore connection system of rated voltage of 1 kV and less

2.3.1.1 Where arrangements are made for the supply of electricity from a source on shore or elsewhere, a connection box complying with the requirements of 3.3.2.11 of this PART is to be installed in a position in the ship suitable for the convenient reception of flexible cables from the external source. Suitable cables having adequate ratings, permanently fixed, are to be provided for connection between the shore connection box and the main switchboard or emergency switchboard.

2.3.1.2 When a three-phase AC system with neutral earthed is adopted for shore and/or ship power, an earth terminal is to be provided for connecting the ship's hull to shore. In the case of DC systems with hull return, the negative terminal of the shore power must be connected to hull.

2.3.1.3 The shore connection is to be provided with an indicator at the main switchboard or emergency

switchboard in order to show when the cables are energized.
2.3.1.4 Where an automatic control device is used for the connection and disconnection of shore supply, the device is to comply with the applicable requirements in Chapter 2 of PART SEVEN of the Rules.
2.3.1.5 In addition to the requirements of 2.3.1.6, an interlocking device between all main generators and emergency generators and the shore supply is to be provided to avoid simultaneous power supply.
2.3.1.6 Where the system has the function of load transfer executed via temporary parallel running between shore supply and ship power, the requirements of 19.2.5.3, 19.2.5.4 and 19.2.6, Chapter 19 of PART EIGHT are to be complied with.

2.3.2 Shore connection system of rated voltage above 1 kV

2.3.2.1 For the shore connection system where load transfer between the shore supply and ship power is executed via blackout, the requirements of 19.2.1.2, 19.2.2, 19.2.3, 19.2.4, 19.2.5.2 and 19.2.6 of Chapter 19, PART EIGHT of the Rules are at least to be complied with.
2.3.2.2 For the shore connection system having the function of load transfer executed via temporary parallel running between shore supply and ship power, the requirements of 19.2.1.2, 19.2.2, 19.2.3, 19.2.4, 19.2.5.3, 19.2.5.4 and 19.2.6 of Chapter 19, PART EIGHT of the Rules are at least to be complied with.
2.3.2.3 The shore supply equipment installed onboard the ship is to comply with the requirements of Section 3, Chapter 19, PART EIGHT of the Rules.

Section 4 POWER SUPPLY AND DISTRIBUTION

2.4.1 Power supply and distribution systems

2.4.1.1 The following systems of distribution may be used:
(1) DC
two-wire insulated system;
two-wire system with negative pole earthed;
single-wire system with negative to hull return.
(2) AC single phase
two-wire insulated system;
two-wire system with one pole earthed;
single-wire system with hull return.
(3) Three-phase AC
three-wire insulated system;
four-wire system with neutral earthed;
three-wire system with neutral earthed and the hull serving as neutral wire.
Other distribution systems than those mentioned above are to be subject to special approval by ISC.
2.4.1.2 For power supply and distribution systems for high-voltage systems, refer to the requirements of 2.14.2.1 of this PART.
2.4.1.3 For the distribution systems of ships intended for the carriage of crude oil and petroleum products in bulk having a flash point (closed-cup test) below 60°C, refer to the requirements of 2.16.2.1 of this PART.

2.4.2 Insulated distribution systems

2.4.2.1 The neutrals of generating sets are not to be connected together in the insulated distribution system.
2.4.2.2 The insulated distribution systems for power, heating and lighting circuits, whether primary or secondary, are to be provided with a device capable of continuously monitoring the insulation level to earth and of giving an audible or visual indication in case of abnormally low insulation values.

2.4.3 Earthed and hull return systems of distribution

2.4.3.1 The hull return system of distribution is not to be used for power, heating or lighting in ships of 1,600 gross tonnage and upwards, but not excluding the following:
(1) impressed current cathodic protective systems;
(2) limited and locally earthed systems, provided that any possible resulting current will not directly flow through any hazardous areas;
(3) insulation level monitoring devices provided the circulation current does not exceed 30 mA under the most unfavourable condition.
2.4.3.2 Where the hull return system is used, all final sub-circuits are to have all poles or phases insulated,

the hull return being achieved by connecting to the hull one of the bus-bars of the distribution board from which they originate.

2.4.3.3 The earthed distribution system in a high-voltage system is to be in compliance with the relevant requirements of 2.14.2.1 of this PART.

2.4.3.4 The earthing conductors used in the hull return system are to be of the same cross-sectional area as the conductors in the insulated pole or phase, and bare conductors are not to be used.

2.4.3.5 Enclosures of equipment or their mounting bolts are not to be used as return conductors or connection to the conductors.

2.4.3.6 The cross-sectional area of earthing conductors which do not normally carry current in service is to be 50% of that of the current-carrying conductors, but not less than 1.5 mm^2.

2.4.3.7 The system earthing of earthed distribution systems is to be effected by means independent of any earthing arrangements of non-current-carrying parts of the electrical equipment.

2.4.4 Voltage and frequency

2.4.4.1 The maximum voltages of AC distribution systems are not to exceed the values given in Table 2.4.4.1.

Maximum Voltages of AC Distribution Systems **Table 2.4.4.1**

No.	Application	Max. voltage (V)
1	For power equipment permanently installed and connected by permanent wiring	15,000
2	(1) For heating and cooking equipment permanently installed and connected by permanent wiring, except space heaters. (2) For portable equipment, which is not hand-held during operation, and with connection by socket outlet which incorporates an earth continuity conductor of a size in accordance with 1.3.4.5 of this PART	1,000
3	(1) For lighting permanently installed (2) For socket outlets supplying the following (which are not specified in items 2 and 4 in the table): ① equipment with double insulation; ② equipment earthed by earth continuity conductors of a size in accordance with 1.3.4.5 of this PART	250
4	For socket outlets used in spaces where particular risks due to exposure and conductivity may exit: (1) supplied with or without the use of isolating transformers; (2) where a safety isolating transformer is used supplying one consuming device only. Both wires of such systems are to be insulated from earth	55① 250
5	Instrumentation and control equipment②	55③ 250

Note: ① For socket outlets with rated voltage up to 24V, the maximum voltage is 55V.
② For the control voltage of distribution systems operating at a voltage above 500 V, see 2.4.4.2 of this Section.
③ For instrumentation and control equipment with rated voltage up to 48V, the maximum voltage is 55V.

2.4.4.2 For distribution systems operating at a voltage above 500 V, the control voltage is to be limited to 230 V, except where all control devices of the distribution systems operating at a voltage not exceeding 1000 V are enclosed in appropriate control boxes.

2.4.4.3 The standard frequency for AC distribution systems is to be 50 Hz or 60 Hz.

2.4.4.4 The maximum voltages of DC distribution systems are not to exceed the values given in Table 2.4.4.4.

Maximum Voltages of DC Distribution Systems **Table 2.4.4.4**

No.	Application	Max. voltage (V)
1	Power equipment	1500
2	Cooking equipment, heating equipment, lighting and socket outlets	500
3	Communication equipment, instrumentation	250
4	Socket outlets supplying power for life boats/rafts	55

2.4.5 Balance of loads

2.4.5.1 For AC three-wire or four-wire systems, the electrical consumers are to be so grouped in the final sub-circuits that the load in each phase will, under normal conditions, be balanced as far as possible within 15% of its rated load at the individual distribution and section boards as well as the main switchboard.

2.4.6 Diversity factors

2.4.6.1 Circuits supplying two or more final sub-circuits are to be rated in accordance with the total connected load subject, where justified, to the application of a diversity factor. Where spare ways are provided on a section or distribution board, an allowance for future increase of load is to be added to the total connected load before application of any diversity factor.

2.4.6.2 The diversity factor may be applied to the calculation of the cross-sectional area of conductors and the rating of switch gear and fuse gear.

2.4.6.3 For cargo winches, a diversity factor may be applied based on the information available from the manufacturer and the information agreed upon between the manufacturer and purchaser. If there is no exact information available, the diversity factors of Table 2.4.6.3 may be applied.

Diversity Factors **Table 2.4.6.3**

Number of motors	Current to be provided for	
	Cases in which motors are of the same size	Cases in which motors are of different sizes
2	100% of combined full load of motors	
3	67% of combined full load of motors	100% of full load of the largest motor + 50% of full load of each one of the other motors
4	62% of combined full load of motors	
5	60% of combined full load of motors	
6 or more	58% of combined full load of motors	

2.4.6.4 For the diversity factors of socket circuits for refrigerated containers, refer to the requirements of Chapter 4, PART FIVE of the Rules.

2.4.7 Power supply to essential services

2.4.7.1 Unless expressly provided otherwise, the primary essential services are to be supplied directly from the main or emergency switchboard (if required), except for the total discrimination.

2.4.8 Power supply to radio equipment and navigation equipment

2.4.8.1 The power supply to the radio equipment as required in Chapter IV (hereinafter referred to as the radio equipment) and the electrical/electronic navigation equipment as required in Chapter V (hereinafter referred to as the navigation equipment) of the SOLAS Convention are to comply with the requirements of 2.4.8.2 to 2.4.8.4.

2.4.8.2 The distribution board of supplies to the radio equipment is to be independent of that of supplies to the navigation equipment.

2.4.8.3 The distribution board of the radio equipment and that of the navigation equipment supplied by the emergency source of electrical power are to be supplied by separate feeders from main and emergency switchboards, and each distribution board is to be provided with a device for changing over between main and emergency sources of electrical power, which is in general to be initiated automatically. In the event of any failure of the power supply of the radio distribution board, an audible and visual alarm is to be given in the navigation bridge.

2.4.8.4 Each consumer is to be supplied by an independent final sub-circuit from its distribution board.

2.4.9 Power supply to auxiliary machinery motors, etc.

2.4.9.1 In addition to the above-mentioned requirements, the power supply to auxiliary machinery motors, illumination, navigation lights, internal communication systems and safety system for ships and persons on board is to comply with the relevant requirements of this PART.

2.4.9.2 For AC distribution systems, final sub-circuits rated over 16A are not to supply more than one equipment, except that they only supply socket outlets with current rating not greater than 32A.

2.4.10 Sockets

2.4.10.1 The sockets for general portable appliances are to be in compliance with the requirements of No.3 and No.4 in Table 2.4.4.1 of this Section.

2.4.10.2 For the sockets of distribution systems operating at different voltages and/or frequencies, non-interchangeable plugs are to be used for connection.

2.4.10.3 No socket outlets are to be provided below floor plates in machinery spaces, or in enclosed fuel

and lubrication oil separator rooms.
2.4.10.4 Where sockets are necessary in cargo holds, they are to be fitted in positions with sufficient protection against mechanical damage.
2.4.10.5 For sockets of refrigerated containers, refer to the relevant requirements of Chapter 4, PART FIVE of the Rules.
2.4.10.6 Socket outlets for power circuits rated over 16A (AC) or 10A (DC) are to be interlocked in such a way that the plug can be neither inserted nor withdrawn when the socket contacts are live.

2.4.11 Power supply with transformers operating in parallel

2.4.11.1 Transformers arranged for parallel operation are to comply with the following requirements:
(1) their winding connections are to be compatible;
(2) their rated voltage ratios are to be equal (with tolerances within permissible limits);
(3) their short-circuit impedance values are to be equal (if expressed in percentage, a ratio within 0.9 to 1.1 may be allowed);
(4) when transformers are intended for operation in parallel, the rated output of the smallest transformer in the group is not to be less than 50% of the rated output of the largest transformer in the group.

2.4.12 Power supply to safety, control and alarm systems of prime movers

2.4.12.1 The prime movers referred to in this paragraph mean diesel engines, gas turbines and steam turbines, etc. that drive the electric generators which comprise the main source of electric power.
2.4.12.2 The safety, control and alarm systems of prime movers are to be supplied by two independent power sources, which and associated wiring are to be such that the requirements of 2.1.1.1(2) of this Chapter can be met in case of single failure.

2.4.13 Power supply to electronic control system of diesel engines

2.4.13.1 The power supply to electronic control systems of diesel engines is to comply with the requirements of 2.2.4 of Appendix 2 to Chapter 9, PART THREE of the Rules.

Section 5 PROTECTION

2.5.1 General requirements

2.5.1.1 Electrical installations are to be suitably protected against overcurrents including short circuits, and other electric faults. The performance and arrangement of the protective devices are to provide complete and coordinated automatic protection to ensure the continuity of supply to available essential services through the discriminative action of the protective devices in the event of a fault elsewhere, and to ensure the elimination of the effects of the fault to reduce damage to the system and hazard of fire. Coordination is to be provided:
(1) between main generator protective device, main bus-bar section breakers (if provided with trip), protective devices (if fitted) of feeders connected to the main bus-bar, and protective devices of feeders from the main bus-bar;
(2) between protective devices of feeders and branch circuits of the distribution board containing essential services, unless otherwise specified in 2.5.3.6 of this Section;
(3) between protective devices of feeders from the emergency generator and the emergency bus-bar, and between protective devices of feeders interconnecting main and emergency switchboards and feeders from the emergency bus-bar.
2.5.1.2 Short-circuit protection is to be provided in each non-earthed pole or phase of distribution systems.
2.5.1.3 Overload protection is to be provided in:
(1) insulated two-wire DC or single-phase AC systems: at least one pole or phase;
(2) insulated three-phase AC systems: at least two phases;
(3) earthed systems: each non-earthed pole or phase.
2.5.1.4 No fuse or non-linked switch is to be inserted in an earthed conductor of distribution systems.

2.5.2 Calculations of short-circuit current

2.5.2.1 In the calculation of the maximum prospective short-circuit current, consideration is to be given to:
(1) all generators which are possibly connected in parallel to reach the maximum required power;
(2) all motors which are normally simultaneously connected in the system.

2.5.2.2 When necessary, the prospective short-circuit power factor of the AC system is to be calculated. If the power factor so obtained is less than the specified one corresponding to the rated short-circuit making or breaking capacity of the selected switch gear, then the breaking capacity of such switch gear is to be reduced accordingly.
2.5.2.3 Short-circuit calculations are to be referred to Appendix 1 of this PART: Short-Circuit Current Calculations with Regard to Electrical Installations, or performed by other methods acceptable to ISC.
2.5.2.4 In general, short-circuit calculations are to be carried out for the following:
(1) short circuit at the output terminal of generators;
(2) short circuit at the main bus-bar;
(3) short circuit at the bus-bars of the emergency switchboard, section switchboards and distribution switchboards;
(4) short circuit at the secondary side of power and lighting transformers.
For the determination of the discriminative action of protective devices, short-circuit calculations are, if necessary, to be additionally performed for short-circuit at terminals of the protected circuit, when only the smallest generator is in supply.

2.5.3 Choice of protective devices against short-circuit

2.5.3.1 Protection against short-circuit currents is to be provided by fuses or circuit-breakers.
2.5.3.2 Unless otherwise specified in 2.5.3.3 and 2.5.3.5, the breaking capacity of protective devices against short-circuit is to comply with the following requirements:
(1) The rated short-circuit breaking capacity of fuses and general circuit breakers is not to be less than the maximum prospective fault current at the point of installation. For the AC systems, the rated short-circuit breaking capacity is not to be less than the prospective symmetrical short-circuit current (root mean square value) at the point of installation.
(2) The rated operating short-circuit breaking capacity (I_{cs}) of circuit breakers for relevant circuits of essential services is not to be less than the maximum prospective fault current at the point of installation. For the AC systems, the rated operating short-circuit breaking capacity is not to be less than the prospective symmetrical short-circuit current (root mean square value) at the point of installation.
2.5.3.3 The rated short-time withstanding current of category B circuit breakers (with short time-lag) is not to be less than the maximum prospective short-circuit current at the instant of contact separation at the point of installation. For the AC systems, the rated short-time withstanding current is not to be less than the prospective symmetrical short-circuit current (root mean square value) at the instant of contact separation at the point of installation.
2.5.3.4 Unless otherwise stated in 2.5.3.5 of this Section, the rated short-circuit making capacity of every circuit breaker or switch which will possibly be initiated for a short-circuit is not to be less than the maximum peak value of the prospective short-circuit current at the point of installation.
2.5.3.5 The use of a circuit-breaker having a short-circuit breaking and/or making capacity less than the maximum prospective short-circuit current at the point of installation is permitted, provided that it is backed up on the generator side by a fuse or by a circuit-breaker (not the generator circuit-breaker) having the necessary rated short-circuit breaking/making capacity.
The short-circuit performance of the back-up protective arrangement is to be at least as that required for a single circuit-breaker by a standard① acceptable to ISC. The circuit-breaker is to have the same utilization category as the circuit-breaker on the load side of the back-up arrangement and a rated short-circuit breaking/making capacity for the maximum prospective short-circuit current at the supply terminal of the arrangement.
2.5.3.6 The back-up protection complying with the requirements of 2.5.3.5 may be used for circuits of non-essential services and of duplicated essential services with automatic change-over. The same fuse or circuit-breaker may be used to back up more than one circuit-breaker when essential services are not involved.
2.5.3.7 Circuit-breakers with fuses connected to the load side may be used, provided the back-up fuse and circuit-breaker are designed for coordinated action, so as to ensure that the operation of the fuse takes place in due time to prevent arcing between poles or between poles and metal parts of the circuit breaker when they are subjected to an overcurrent involving the operation of the fuse.
2.5.3.8 When determining the short-circuit performance requirements for the above-mentioned back-up protection arrangement, the impedance of the elements of the arrangement may be taken into account, such as the impedance of a cable connection when the circuit-breaker on the load side is far away from the back-up circuit-breaker or fuse.

---

① Refer to IEC Publication 60947-2: Low-Voltage Switch Gear and Control Gear – Part 2: Circuit-Breakers.

2.5.4 Selective protection for short-circuit

2.5.4.1 Unless otherwise stated in 2.5.3.6 of this Section, the short-circuit protection of essential services is to be selective and comply with the following:

(1) to ensure that only the protective device nearest to the fault initiates disconnection of the defective circuit in the case of short-circuit;

(2) the tripping time of the protective devices connected in series is to be carefully coordinated;

(3) during the required time of selective protection, the protective device is to be capable of carrying the short-circuit current without breaking at the point of installation.

2.5.5 Choice of protective devices against overload

2.5.5.1 Circuit breakers provided for overload protection are to have a tripping characteristic (overcurrent − trip time) adequate for the overloading ability of protected elements and for any discrimination requirement of the system.

2.5.5.2 The use of fuses for overload protection is permissible up to 320 A, provided they have suitable characteristics, but the use of circuit breakers or similar devices for protection against overload above 200 A is recommended.

2.5.6 Protection of generators

2.5.6.1 Unless otherwise provided in 2.5.6.8 of this section, generators are to be protected against short-circuit and overloads by circuit breakers arranged to interrupt simultaneously all insulated poles, and the overload protection is to be adequate for the thermal capacity of the generator. In addition, the following requirements are to be complied with:

(1) for overloads between 10% and 50%, the circuit breaker is to be tripped with a time delay of less than 2 min. It is recommended that the circuit breaker be set within the limits of 125 to 135% of the rated current of the generator and with a time delay of 15 to 30 s;

(2) for overcurrents in excess of 50% but less than the steady short-circuit current of the generator, the circuit breaker is to be tripped after a short-time delay required for the discriminative protection of the system.

It is recommended that the pick-up current for tripping of the circuit-breaker after a short-time delay be set at 200% to 250% of the rated current of the generator and with a maximum time delay of 0.2 s (DC) or 0.6 s (AC);

(3) circuit breakers for three or more generators connected in parallel are also to be provided with instantaneous releases which are to be set slightly greater than the maximum short-circuit current of the generators protected so that the circuit-breaker may break instantaneously. Other equivalent means may also be accepted subject to the agreement of ISC.

2.5.6.2 For generators less than 50 kW (or kVA) in unit capacity and not arranged to operate in parallel, a multi-pole linked switch with a fuse in each insulated pole may be fitted for protection.

2.5.6.3 Generators having a capacity of 1,500 kVA or above are to be equipped with a suitable protective device or system which, in the event of a short-circuit in the generator or in the supply cable between the generator and its circuit breaker will de-excite the generator and open the circuit breaker. This does not apply to emergency generators.

2.5.6.4 AC generators arranged to operate in parallel are to be provided with a reverse-power protection, with a time delay set within 3 to 10 s. DC generators arranged for parallel operation are to be provided with instantaneous or short-time delayed (less than one second) reverse current protection. The setting of reverse power (or reverse current) protection of generators arranged for parallel operation, dependent on the type of the prime mover used, is to be as follows:

(1) for diesel engines − 8% to 15% of the rated power (or current) of the generator;

(2) for steam turbines − 2% to 6% of the rated power (or current) of the generator.

A fall of 50% in the applied voltage is not to render the reverse power (or reverse current) protection inoperative, although it may alter the amount of reverse power required to open the breaker.

For the reverse-current protection, due consideration is to be given to the reverse current resulting from the ship's network (e.g. cargo winches).

Where equalizer leads are provided, the reverse current protection is to be connected to the positive pole of DC generators.

2.5.6.5 Generators arranged to operate in parallel are to be provided with undervoltage protection as follows:

(1) the operation of undervoltage release is to be instantaneous, if used to prevent the circuit-breaker from closing when the generator is not generating electrical energy;

(2) when the voltage drops down to 70% ~ 35% of the rated voltage, the undervoltage release is to operate

with a time delay for discrimination purpose.
2.5.6.6 Where turbine-driven DC generating sets are arranged to operate in parallel, means are to be provided for the purpose of opening simultaneously all circuit-breakers of the generators when the overspeed tripping device of the driving turbine functions.
2.5.6.7 In the case of substantial reduction of speed of generators, the protective devices associated with generators are to remain effective.
2.5.6.8 Emergency generators are to be protected against short-circuit. Audible and visual alarm signals are to be given in the event of over-currents of emergency generators, which are not to lead to tripping of the circuit breakers of emergency generators.

2.5.7 Automatic load shedding

2.5.7.1 Proper load shedding or other equivalent arrangements are to be provided to automatically shed non-essential services, services for habitable conditions and where necessary, secondary essential services to ensure that the connected generator(s) is/are not overloaded. This load shedding may be carried out in one or more stages according to the overloading ability of the generator. In such case, the non-essential services are to be shed firstly.

2.5.8 Protection of power and lighting transformers

2.5.8.1 The primary windings of power and lighting transformers are to be protected against short-circuit and overload by multi-pole circuit-breakers or fuses. Overload protection may also be provided in the secondary windings.
2.5.8.2 When transformers are arranged to operate in parallel, means of isolation are to be provided on the secondary windings. Switches and circuit breakers used for this purpose are to be capable of withstanding surge currents.

2.5.9 Protection of feeder circuits

2.5.9.1 Each feeder circuit is to be protected against overload and short circuits by a multi-pole circuit breaker arranged to interrupt simultaneously all insulated poles, or a multi-pole switch with fuses, but for a transitional emergency lighting feeder circuit it may also be accepted to use fuses only.
2.5.9.2 When a multi-pole switch with fuses is used, the following requirements are to be complied with:
(1) the fuse in the feeder sub-circuit from the main switchboard is to be fitted between the bus-bar and the switch;
(2) where the final sub-circuit from the distribution board has a rated current not exceeding 60 A and the consumers supplied by it can be disconnected at a nearby position, the switch may be omitted.
2.5.9.3 Circuits supplying consuming devices protected individually against overload (e.g. motors) may be provided with short-circuit protection only.
2.5.9.4 The protection of the steering gear circuits is to comply with 13.1.9.2 of PART THREE of the Rules.
2.5.9.5 Permanently fixed cables between the shore connection box and the main switchboard are to be protected by a circuit-breaker or an isolating switch and fuses. Such protection is to be fitted in the shore connection box.
2.5.9.6 In general, the interconnector feeder supplying the emergency switchboard from the main switchboard is to be protected at the main switchboard against overload and short-circuit. Where the system is arranged also for reverse power supply, the interconnector feeder is to be additionally protected at the emergency switchboard at least against short-circuit.

2.5.10 Protection of motors

2.5.10.1 Motors rated at 1.0 kW or above and all motors for essential services are to be protected individually against overload and short-circuit, and against undervoltage as required in 2.5.10.6 of this Section. The short-circuit protection can be provided by the same protective device for both the motor and its supply cable.
2.5.10.2 Protection of steering gear motors is to comply with 13.1.9.2 of PART THREE of the Rules.
2.5.10.3 The protective devices are to be designed to allow the flow of currents during the normal accelerating period of motors under normal conditions of service. When the time-current characteristics of the overload protective device of a motor are not adequate for the starting period of the motor, the overload protecting device may be rendered inoperative during the accelerating period provided that the protection against short-circuit remains operative and that the suppression of the overload protection is only temporary.
2.5.10.4 For continuous duty motors, protective devices are to have a time delay characteristic which

ensures reliable thermal protection of the motors for overload conditions. The maximum continuous current of the protective device is not to exceed 125% of the rated current of the protected motor.
2.5.10.5 For intermittent duty motors, the current setting and the delay characteristics for protective devices are to be chosen after considering the actual service condition.
2.5.10.6 Motors are to be provided with either:
(1) undervoltage protection, operative on the reduction or failure of voltage, to cause and maintain the interruption of power in the circuit until the motor is deliberately restarted; or
(2) undervoltage release, operative on the reduction or failure of voltage, to cause and maintain the interruption of power in the circuit, but so arranged that the motor restarts automatically and without excessive voltage drop or starting current on restoration of voltage.
The protective devices are to allow the motor to start when the voltage is above 85% of the rated voltage, and are without fail to intervene when the voltage is lower than approximately 20% of the rated voltage, at the rated frequency and with time delay when necessary.
2.5.10.7 When fuses are used to protect poly-phase motor circuits, consideration is to be given to protection against single phasing.

2.5.11 Protection of lighting circuits
2.5.11.1 Each lighting circuit is to be protected against overload and short-circuit.

2.5.12 Protection of storage batteries
2.5.12.1 Storage batteries, other than engine starting batteries, are to be protected against short-circuit with devices placed as near as practicable to the batteries.
2.5.12.2 Each battery charger is to be properly protected against discharging of the battery due to the reduction or loss of charging voltage.

2.5.13 Protection of meters, pilot lamps and control circuits
2.5.13.1 Voltmeters, voltage coils of measuring instruments, earthing indicators and pilot lamps together with their connecting leads are to be protected by fuses. A pilot lamp need not be individually protected provided the following conditions are satisfied:
(1) the pilot lamp is installed with the equipment in the same enclosure;
(2) the pilot lamp is supplied from the interior circuit of the enclosure of the equipment;
(3) the protection device in the circuit is rated less than 25 A;
(4) a fault in the pilot lamp would not jeopardize the supply to essential services.
2.5.13.2 The voltage coils of control and protective devices and equipment are to be protected by fuses. The coils themselves need not be protected provided the following conditions are satisfied:
(1) the coils are installed with the equipment in the same enclosure and protected by a general protective device;
(2) the coils are supplied from circuits of the equipment and the protective device of such circuits is rated less than 25 A.

2.5.14 Protection of semiconductor equipment
2.5.14.1 Semiconductor equipment is to be protected against overload and short circuit.

Section 6 AUXILIARY MACHINERIES

2.6.1 General requirements
2.6.1.1 Motors rated at 1.0 kW or above and motors required for essential services are to be supplied from distribution boards by separate final sub-circuits.
2.6.1.2 Every electric motor is to be provided with efficient means of starting and stopping which are, in general, placed near the motor, so as to be easily operated by the person controlling the motor.
2.6.1.3 Means are to be provided for the disconnection of the full load from all live poles of supply of every motor rated at 0.5 kW or above and its control gear. Where the control gear is mounted on or adjacent to a main or other distribution switchboard, a disconnecting switch in the switchboard may be used for this purpose. Otherwise, a disconnecting switch within the control gear enclosure or a separate enclosed disconnecting switch is to be provided.
2.6.1.4 When the starter or any other apparatus for disconnecting the motor is remote from the motor, it is required that either:
(1) provision be made for locking the circuit disconnecting in the OFF position; or

(2) an additional disconnecting-switch be fitted near the motor; or
(3) the fuse in each live pole or phase be so arranged that it can be readily removed and retained by an authorized person.
2.6.1.5 Where a single master-starter system (i.e. a starter used for controlling a number of motors successively) is used, undervoltage and over-current protection, means of isolation and a running indicator are to be provided for each motor, not less effective than those required for systems using a separate starter for each motor. Where the starter system is of an automatic type, suitable alternative means are to be provided for manual operation. Where the starter is used for motors for essential services, the starting portion is to be duplicated, and means are to be provided for change-over in the event of failure of one of the starters.
2.6.1.6 All motors with field adjustment for speed control are to be provided with a device which renders the motors to be started only when the field is fully excited.
2.6.1.7 The undervoltage, overload and short-circuit protection for motors are to comply with the requirements of Section 5, Chapter 2 of this PART.

2.6.2 Steering gear
2.6.2.1 Electrical or electrohydraulic steering gears are to comply with the relevant requirements of Chapter 13, PART THREE of the Rules.

2.6.3 Permanently installed submersible bilge pumps
2.6.3.1 The motors of permanently installed submersible bilge pumps are to be connected to the emergency switchboard. The feeder cables are to be installed in continuous lengths from above the bulkhead to the motor terminals.
The cables are to be impervious-sheathed and armoured. Cables and their connections to such pumps are to be capable of operating under a head of water equal to the height of the bulkhead deck.
2.6.3.2 Under all circumstances it is to be possible to start the motor of a permanently installed submersible bilge pump from a position above the bulkhead deck. If an additional start-stop push button is provided near the motor, the circuits are to be so arranged as to ensure that all control circuits of the start-stop push button may be disconnected from the position above the bulkhead deck.
2.6.3.3 The power source of a permanently installed submersible bilge pump is also to comply with the relevant requirements of Section 5, Chapter 3, PART THREE of the Rules.

2.6.4 Deck machinery
2.6.4.1 Electromagnetic brakes for electrical deck machinery are to have, in addition, a hand release device.
2.6.4.2 If not otherwise specially required in their specifications, the duty of windlass motors and winch motors is to be rated for not less than 30 min.
2.6.4.3 Boat winch motors are to be provided with limit switches for cutting off the power supply upon returning of the boat to its original position.
2.6.4.4 The control device of boat winch motors is to be interlocked with the manual drive and manual brake.

2.6.5 Fire safety equipment
2.6.5.1 The electrical power supply to fire pump motors and fixed emergency fire pump motors is to comply with the relevant requirements of this PART.
2.6.5.2 The electrical power supply to automatic sprinkler systems and water-spraying systems is to comply with the relevant requirements of the International Code for Fire Safety Systems.

2.6.6 Stopping of ventilating fans and oil pumps
2.6.6.1 Power ventilation of accommodation spaces, service spaces, cargo spaces and control stations is to be capable of being stopped from an easily accessible position outside the space being served. This position is not to be readily cut off in the event of a fire in the space served.
The exhaust fans in the exhaust ducts from galley ranges are to be capable of being shut off within the galley.
2.6.6.2 Stopping of the ventilation fans and oil pumps in machinery spaces
(1) The means provided for stopping the power ventilation serving the machinery spaces are to be grouped so as to be operable from two positions outside the space served, one of which is to be easily accessible and close to such space, and is not to be readily cut off in the event of a fire in the space served.
The means provided for stopping the power ventilation of the machinery spaces are to be entirely separate

from the means provided for stopping ventilation of other spaces.
(2) Means of control are to be provided for stopping forced and induced draught fans, oil fuel transfer pumps, oil fuel unit pumps, lubricating oil service pumps, thermal oil circulating pumps and oil separators (purifiers). Except oil separators, such means of control are to be situated outside each related space so that it will not to be cut off in the event of a fire in the space served.
2.6.6.3 Additional requirements for passenger ships
(1) In passenger ships, the controls required in 2.6.6.2 of this Section are to be situated at one control position or grouped in as few positions as possible. Such positions are to have safe access from the open deck.
(2) In passenger ships carrying more than 36 passengers, power ventilation, except machinery space and cargo space ventilation and unless otherwise specified in PART SIX of the Rules, is to be fitted with controls so grouped that all fans may be stopped from either of two separate positions which are to be situated as far apart as practicable.
Fans serving power ventilation systems to cargo spaces are to be capable of being stopped from a safe position outside such spaces.

2.6.7 Integrated cargo and ballast systems on tankers

2.6.7.1 The following requirements are applicable to integrated cargo and ballast systems on tankers.
2.6.7.2 An integrated cargo and ballast system means any integrated hydraulic and/or electric system used to simultaneously drive both cargo and ballast pumps (including active control and safety systems and excluding passive components, e.g. piping).
2.6.7.3 The operation of the cargo and/or ballast systems may be necessary, in certain emergencies or during navigation, to enhance the safety of the tanker, and measures are to be taken to prevent cargo and ballast pumps becoming inoperative simultaneously due to a single failure in the integrated cargo and ballast system (including its control and safety systems).
2.6.7.4 The following design features are, inter alia, to be fitted:
(1) the emergency stop circuits of the cargo and ballast systems are to be independent from the circuits of the control systems. A single failure in the control system circuits or the emergency stop circuits is not to render the integrated cargo and ballast system inoperative;
(2) manual emergency stops of the cargo pumps are to be arranged in a way that they will not cause the stop of the power pack, rendering ballast pumps inoperable;
(3) the control systems are to be provided with backup power supply, which may be achieved by duplicated power supply from the main switch board. The failure of any power supply is to activate an audible and visual alarm at each location where the control panel is fitted;
(4) in the event of failure of an automatic or remote control system, a secondary means of control is to be available for the operation of the integrated cargo and ballast system. This may be achieved by manual overriding and/or redundancy control arrangements within the control system.

2.6.8 Vehicle ramp control system for ferries

2.6.8.1 The vehicle ramp control station is to be so arranged that the movement of the ramp can be observed by the operator.
2.6.8.2 An audible and visual alarm is to be given for power failure of the control system. At the same time, the ramp is to be kept at its position automatically. When the power supply is recovered, operation of the control mechanism is not to be continued until it its reset.
2.6.8.3 The indicator of ramp conditions is to be provided in the control station.
2.6.8.4 Devices for preventing control and driving circuits from action are to be provided under the following conditions:
(1) any of the covers is not taken off;
(2) enclosures of vehicles are not closed.
2.6.8.5 Audible and visual indications are to be given continuously at a conspicuous position by the ramp when the ramp is running.
2.6.8.6 Where the ramp is fixed by a retractable locking device, means are to be provided to ensure that the power will not be interrupted when the locking device is clutched and that no launching of the ramp is possible before the locking device is disengaged.
2.6.8.7 Where a ramp, in addition to that for the stern door, is provided for access from the wharf, its angle to the horizontal is to be less than 10° before the stern door is opened or closed.
2.6.8.8 The maximum inclination of the access ramp in operation to the horizontal is not to be more than the predetermined angle. An audible and visual alarm is to be given if the inclination exceeds the allowable angle.

2.6.8.9 Where a remote locking device is fitted, alternative means is to be provided for locking the ramp in case of failure of the locking control or locking mechanism.

Section 7 LIGHTING AND NAVIGATION LIGHTS

2.7.1 General requirements

2.7.1.1 The lighting fittings fitted in cargo holds, exterior passageways, or other spaces where they are liable to mechanical damage, are to be provided with robust protective grids.

The lighting fittings located in such spaces where they are liable to considerable vibration are to be provided with means for damping the vibration.

Where lighting fittings are directly fixed on wooden panelling or other inflammable materials, precautions are to be taken against overheating and fire.

2.7.1.2 The switches of lighting fittings for baggage rooms, mail rooms, provisions rooms, refrigerated spaces and other similar spaces are not to be fitted inside such spaces, and are to be provided with a pilot lamp. Switches for lighting used in wet spaces and in spaces where the risk of explosion might arise are to be capable of isolating all insulated poles.

2.7.1.3 The warning signs showing "DANGER! HIGH VOLTAGE!" are to be provided in the spaces adjacent to discharge lamps operating at a voltage over 250 V and elsewhere as necessary.

2.7.2 Supply and control

2.7.2.1 The lighting point supplied by each final sub-circuit of rating of more than 16 A at the lighting distribution board is not to exceed one. The number of lighting points supplied by each final sub-circuit of rating 16 A or less at the lighting distribution board is not to exceed:

10 for circuits of rating 55 V or less;

14 for circuits of rating 56 ~ 120 V circuits;

24 for circuits of rating 121 ~ 250 V circuits.

In final sub-circuits for cornice lighting, panel lighting and electrical signs where lampholders are closely grouped, the number of points supplied is unrestricted provided that maximum operating current in the sub-circuit does not exceed 10 A.

Final sub-circuits for lighting are not to supply heating and power appliances, except for small galley equipment (e.g. toasters, mixers, coffee makers), small motors (e.g. of desk and cabin fans, refrigerators), wardrobe heaters and similar items.

2.7.2.2 The lighting for main engine rooms, large machinery spaces other than main engine rooms, large galleys, passageways (including accesses), stairways leading to boat decks, public spaces and berthing compartments accommodating more than 16 passengers is to be supplied by at least two final sub-circuits, and one of which may be the final sub-circuit for emergency lighting so that in the event of failure of any one of the sub-circuits the other one could still maintain the necessary lighting for such spaces. The lighting points for main engine and boiler rooms are to be distributed alternately.

In machinery spaces, the oil fuel system containing heated oil under pressure exceeding 0.18 MPa are to be adequately illuminated so that defects and leakage will readily be observed. In machinery spaces of category A and whenever practicable in other machinery spaces, the arrangements for storage, distribution and utilization of oil used in pressure lubrication systems are also to be adequately illuminated.

2.7.2.3 Each main vertical fire zone is to be provided with at least two separate lighting feeders, one of which may be an emergency light feeder.

2.7.2.4 The permanently fixed lighting in cargo holds is to be controlled by switches located in a suitable position outside the cargo holds, capable of isolating all insulated poles and provided with a pilot lamp to indicate the power supply.

2.7.2.5 The degree of protection of lighting fittings located in various spaces in ships is to comply with the requirements of Table 1.3.2.2 of this PART. Lighting switches for spaces with special requirements are to be installed in accordance with the requirements of 2.7.1.2 of this Section.

2.7.2.6 Lighting circuits are to be provided with protection in accordance with the requirements of 2.5.11.1 of this Chapter.

2.7.2.7 A main electrical lighting system is to provide illumination throughout those parts of the ship normally accessible to and used by passengers or crew, and is to be supplied from the main source of electrical power.

2.7.2.8 In assessing the current rating of lighting circuits, in case of lack of accurate information, every lampholder is to be assessed at the maximum load likely to be connected to it, with a minimum of 60 W, unless the fitting is so connected as to take only a lamp rated at less than 60 W. 200VA are to be counted for

each lighting socket in accommodation spaces.

2.7.3 Emergency lighting

2.7.3.1 The arrangement of emergency lighting and the supplementary emergency lighting for ro-ro passenger ships are to comply with the relevant requirements of Section 2 of this Chapter.

2.7.3.2 In passenger ships, the means of escape, including stairways and exits, are to be marked by lighting or photo-luminescent strip indicators complying with acceptable standards① and placed not more than 0.3 m above the deck at all points of the escape route including angles and intersections. The marking must enable passengers to identify the routes of escape and readily identify the escape exits.

If electric illumination is used, it is to be supplied by the emergency source of power (see 2.2.2.1(1)③ of this Chapter).

2.7.3.3 All emergency lighting fittings are to be provided with a prominent mark or structurally different from other luminaries.

2.7.3.4 No local switch is to be installed in the transitional emergency lighting feeders.

2.7.3.5 No local switch is to be installed in the emergency lighting circuits in the spaces so specified in 2.2.2.1(1) and 2.2.3.1(2) of this Chapter except for the emergency lights in the navigation bridge, at the stowage positions of lifeboats and life rafts.

2.7.3.6 Respective power sources of main and emergency switchboards, associated transforming equipment (if any), the main or emergency switchboard and lighting switchboard (excluding section board and distribution board) are not to be provided in the same space so that the two systems would not fail simultaneously in the event of a fire or other casualty in any space containing these appliances.

2.7.3.7 In passenger ships, supplementary lighting shall be provided in all cabins to clearly indicate the exit so that occupants will be able to find their way to the door. Such lighting, which may be connected to an emergency source of power or have a self-contained source of electrical power in each cabin, shall automatically illuminate when power to the normal cabin lighting is lost and remain on for a minimum of 30 min.

2.7.4 Navigation lights

2.7.4.1 Each navigation light is to be supplied by a sub-circuit connected separately to the control box fitted at an easily accessible position on the navigation bridge and is to be controlled and protected in each insulated pole by a switch and a fuse or by a circuit breaker fitted in the control box.

2.7.4.2 The control box for navigation lights is to be supplied directly from the main switchboard and emergency switchboard. Where the transitional source of emergency power is provided according to Section 2 of this Chapter, the control box is to be supplied directly from the emergency switchboard and transitional emergency charging and discharging switchboard.

2.7.4.3 The change-over switch for the supply circuits required in 2.7.4.2 of this Section is to be installed on the control box or at a suitable position on the navigation bridge.

2.7.4.4 Each navigation light is to be provided with an automatic indicator giving an audible and visual indication of failure of the light. If a visual signal is used and connected in series with the navigation light, means are to be provided to prevent extinction of the navigation light due to failure of the signal, and the audible and visual alarms for failure of the power source of the control box are to be provided.

2.7.4.5 The power supply from the control box of navigation lights may be extended to the signal lights required in the International Regulations for Preventing Collisions at Sea, and other consumers are not to be connected to the box.

Section 8 INTERNAL COMMUNICATION SYSTEMS

2.8.1 Main engine telegraph system

2.8.1.1 At least two independent means are to be provided for communicating orders from the navigating bridge to the position in the machinery space or in the control room from which the speed and direction of thrust of the propeller (hereinafter referred to as the normal control position of the propeller) are normally controlled. One of the means is to be the main engine telegraph system complying with the requirements of 2.8.1.2 of this Section.

2.8.1.2 The main engine telegraph system is to be in compliance with the following requirements:

(1) The controls of the transmitters and receivers are to be safeguarded by suitable means against being

---

① Refer to the Guidelines for the Evaluation, Testing and Application of Low-Location Lighting on Passenger Ships adopted by IMO resolution A.752(18).

inadvertently moved.
(2) The engine telegraph is to be a two-way system in which the signal given by the receiver is also immediately discernible at the transmitter.
(3) In the case of installations with several control positions the acknowledged command must be indicated at all control positions. Where a control position is selected by switching, an additional indication is to be provided to show which one is in use.
(4) Both the transmitter and the receiver are to be equipped with a call-up device which remains in operation from the start of the command transmission till it is correctly acknowledged. The audible signal is to be audible at any position in the engine room. If necessary, a visual signal is to be provided in addition to the audible signal.
(5) An audible alarm is to be provided for wrong direction of rotation of the main engine (applicable to reversible main engines) in the normal control position of the propeller.
(6) Power is to be supplied by the independent final sub-circuit and audible and visual alarms are to be provided on the navigation bridge for the purpose of indicating the failure of power supply.
2.8.1.3 The other means for communicating orders required in 2.8.1.1 may be an emergency engine telegraph system, the functions of which are to be in compliance with the requirements of 2.8.1.2(1) and (2), and which is to be supplied by the emergency power source.
2.8.1.4 A telephone system required in 2.8.2.2(4) may be fitted instead of the emergency engine telephone system.

2.8.2 Important telephone systems
2.8.2.1 The important telephone systems are to be such as to ensure clear vocal intercommunication in all conditions of the ship.
2.8.2.2 The telephone system is to be provided in the following spaces:
(1) Bridge – Engine control room;
(2) Bridge – Steering gear control position in steering gear compartment;
(3) Bridge – Radio room, not required if communication can be made without telephone;
(4) Bridge – Normal control position of the propeller, not required if an emergency main engine telegraph system is provided;
(5) Bridge – Other control positions of the propeller, not required if a repeater of the main engine telegraph is provided in these positions;
(6) Engine control room – Other control positions of the propeller, not required if a repeater of the main engine telegraph is provided in these positions.
2.8.2.3 The telephone systems required in 2.8.2.2 are to be individual links, although a common telephone system may be used if it is ensured that the bridge can cut into existing conversations at all times.
2.8.2.4 The common telephone system described in 2.8.2.3 is to be an independent one and is allowed to provide voice communications, in addition to the spaces described in 2.8.2.2, only for those that are relevant to ship safety, such as the fire control station, CO_2 room and emergency generator room, etc.
2.8.2.5 Two-way calling equipment is to be provided for the telephone systems fitted in the engine room (except engine control room) and designed as being audible at any position in the engine room under full-power operation of the main propelling plant, and visual signals are to be provided in addition to the audible signals.
2.8.2.6 The important telephone system is to remain operable in case of failure of the main power supply.

2.8.3 Communication in an emergency
2.8.3.1 An intercommunication system is to be provided which enables commands to be transmitted between strategic positions, i.e. the emergency control station, the muster and embarkation station of survival craft and navigation bridge etc.
2.8.3.2 The communication system may comprise portable or permanently installed equipment, and is to remain operable in case of failure of the main power supply.

2.8.4 Engineers' alarms
2.8.4.1 An engineers' alarm is to be provided to be operated from the engine room or engine control room and is to be clearly audible in the engineers' accommodation.
2.8.4.2 The audible alarm may be mounted centrally in the passageway of the engineers' accommodation, or individually in the cabins and the mess.
Where a decentralized arrangement is used, it is to be possible to transmit the alarm to the engineers both individually and collectively.

Section 9 SAFETY SYSTEMS FOR SHIPS AND PERSONS ONBOARD

2.9.1 General emergency alarms

2.9.1.1 In order to sound general emergency signals, a general emergency alarm system comprised of the ship's whistle or siren and additionally an electrically operated bell or klaxon or other equivalent apparatus, is to be provided on all passenger ships and cargo ships of 500 gross tonnage and above. In passenger ships, the alarm is to be capable of being given separately or simultaneously to crew and passengers. Cargo ships of 500 gross tonnage and above may not be fitted with an independent general emergency alarm system when a public address system meeting the requirements of 2.9.2.1 (1) to (8) has already been provided.

2.9.1.2 The system is to be capable of operation from the navigation bridge and, except for the ship's whistle or siren, also from at least one other strategic points[①]. The alarm is to continue to function after it has been triggered until it is manually turned off or is temporarily interrupted by a message from the public address system. For passenger ships there is also to be an additional activation point in the safety centre.

2.9.1.3 Where the general emergency alarm system is in operation, the acoustic system for entertainment is to be interrupted automatically.

2.9.1.4 The general alarm system is to be supplied from special feeders, being capable of automatically converting to the emergency source of electrical power in the event of failure of the main source of electrical power. In passenger ships, the system is also to be capable of being supplied by a temporary emergency source of electrical power.

2.9.1.5 The system is to be audible throughout all the accommodation and normal crew working spaces, including open decks in passenger ships.

The minimum sound pressure level for the emergency alarm tone in interior and exterior spaces is to be 80 dB(A) and at least 10 dB(A) above ambient noise levels existing during normal equipment operation with the ship underway in moderate weather. The sound pressure levels at the sleeping position in cabins and in cabin bathrooms are to be at least 75 dB(A) and at least 10 dB(A) above ambient noise levels.

2.9.1.6 Each electrically operated bell or klaxon or other equivalent warning system is to be separately protected against short circuit.

2.9.2 Public address system

2.9.2.1 Cargo ships of 500 gross tonnage and above are to be provided with a public address system in compliance with the following requirements:

(1) capable of broadcasting messages from the navigation bridge and fire control station etc. to all spaces where crew are normally present and muster stations;

(2) no operation required of receivers to accept the broadcast message;

(3) protected against unauthorized use;

(4) amplifiers have sufficient output power so that all loudspeakers for the purpose of emergency announcement can be operated at the same time;

(5) arranged to prevent feedback or any other interference;

(6) with the ship underway in normal conditions, the minimum sound pressure level for broadcasting emergency announcements is to be:

① in interior spaces 75 dB(A) and at least 20 dB(A) above the speech interference level;

② in exterior spaces 80 dB(A) and at least 15 dB(A) above the speech interference level;

(7) capable of being supplied by both main and emergency power sources;

(8) if the public address system is used to give the general alarm, the following requirements are to be fulfilled:

① the performance requirements of 2.9.1 of this Section are to be complied with;

② at least two amplifiers are to be provided, each of them separately supplied;

③ the loudspeaker circuits are to be so arranged that an announcement at a reduced acoustic irradiation is maintained in the event of a failure of an amplifier or loudspeaker circuit;

④ where loudspeakers with built-in volume controls are used, the volume controls are to be disabled by the release of the alarm signal;

⑤ it is to be possible to transmit the clearly audible alarm signal at all times and other simultaneous signal transmissions are to be automatically interrupted;

---

① Other strategic points are taken to mean those locations, other than the navigation bridge, from where emergency situations are intended to be controlled and the general alarm system can be activated. A fire control station or a cargo control station should normally be regarded as strategic points.

⑥ an independent short-circuit protection is to be provided for each loudspeaker.

2.9.2.2 All passenger ships are to be provided with a public address system in compliance with the following requirements:

(1) capable of simultaneously broadcasting messages from bridge and central control station, etc. to all spaces where crew and passengers or both are normally present and muster stations, and capable of broadcasting messages to crew and passengers separately;

(2) complying with the requirements of 2.9.2.1(2) to (6);

(3) capable of interrupting at the control position on the navigation bridge any broadcast of the system from any other position onboard;

(4) the spaces where control units of the system are located are the control stations as defined in Chapter II-2 of the SOLAS Convention, and each of the control stations is to be provided with the following emergency function controls:

① clearly indicating any emergency function;

② automatically overriding any other input system or programme;

③ automatically overriding all volume controls and on/off controls so that the required volume for the emergency mode is achieved in all spaces;

(5) at least two independent and separate amplifiers are to be provided, each of them separately supplied;

(6) at least two loudspeaker circuits connected to their respective amplifiers are to be installed in each fire zone, and their cables are to be laid as widely apart as practicable for their entire length;

(7) independent short-circuit protection is to be provided for each loudspeaker;

(8) capable of being supplied by main, emergency and temporary emergency sources of electrical power;

(9) if the public address system is used to give the general emergency alarm, the requirements of 2.9.1 of this Section are also to be complied with.

2.9.3 Pre-discharge alarms of fire extinguishing medium

2.9.3.1 In any ro-ro spaces, container holds equipped with integral reefer containers, spaces accessible by doors or hatches (except general cargo holds), and other spaces in which personnel normally work or to which they have access, which are protected by fixed gas fire-extinguishing systems, means are to be provided for automatically activating audible and visual alarms for the release of fire-extinguishing medium. The alarms are to operate for the time required to evacuate the space, but in no case less than 20 s before the medium is released.

2.9.3.2 Machinery spaces, cargo pump-rooms, vehicle spaces, ro-ro spaces and special category spaces which are protected by fixed high-expansion foam fire-extinguishing systems are to be provided with audible and visual alarms for the release of fire-extinguishing medium in order to give warning of the release of the system. The alarms are to operate for the time required to evacuate the space, but in no case less than 20 s before the medium is released.

2.9.3.3 The above-mentioned alarm system is to be supplied by the emergency source of electrical power.

2.9.3.4 The fixed fire-extinguishing system for the protection of machinery spaces where main propulsion engine and main generator set are located is to be designed such that any action other than the release of fire extinguishing media are not to lead to automatic shutdown of ventilation fans and oil pumps in these machinery spaces,such as opening the release box (cabinet) door during fire drills.

2.9.4 Elevator alarms

2.9.4.1 Elevators having an internal control are to be fitted with an emergency audible call-up device capable of being operated in the car and the alarm signal is to be transmitted to the positions where persons are normally present.

2.9.4.2 The emergency audible call-up device is to be independent from the power and control circuits of the elevator and supplied by the emergency source of electrical power.

2.9.5 Alarms for closing refrigerated spaces

2.9.5.1 Where the doors to refrigerated spaces such as refrigerated holds and refrigerating food chambers cannot be opened from the inside, an alarm capable of being activated within the spaces upon inadvertent closing of such doors is to be fitted and the alarm transmitted to normally manned positions.

2.9.6 Fire detection and fire alarm systems

2.9.6.1 The fire detection and fire alarm systems are to comply with the relevant requirements of Chapter II-2 of the SOLAS Convention in force and Chapter 9 of the International Code for Fire Safety Systems.

2.9.6.2 There are to be not less than two sources of power supply for the fixed fire detection and fire alarm system, one of which is to be an emergency source. The supply is to be provided by separate feeders

reserved solely for that purpose. Such feeders are to run to an automatic change-over switch situated in or adjacent to the control panel for the fire detection system. The main (respective emergency) feeder shall run from the main (respective emergency) switchboard to the change-over switch without passing through any other distributing switchboard.

2.9.6.3 Operation of the automatic changeover switch or a failure of one of the power supplies is not to result in permanent or temporary degradation of the fixed fire detection and fire alarm system.

2.9.6.4 Where the fixed fire detection and fire alarm system would be degraded by the momentary loss of power, a source of stored energy having adequate capacity is to be provided to ensure the continuous operation during changeover between power supplies.

2.9.6.5 Connection of electrical power supplies to an automatic changeover switch is to be arranged such that a fault will not result in the loss of all supplies to the automatic changeover switch.

2.9.6.6 The fixed fire detection and fire alarm system emergency power may be supplied by an accumulator battery. Where the system is supplied from an accumulator battery, the arrangements are to comply with the following requirements:

(1) The accumulator battery is to have the capacity to operate the fire detection system under normal and alarm conditions during the period required by 2.2.2 or 2.2.3 of this Chapter for the emergency source of power supply.

(2) The rating of the charge unit, on restoration of the input power, is to be sufficient to recharge the batteries while maintaining the output supply to the fire detection system.

(3) The accumulator batteries are to be suitably located for use in an emergency.

(4) The feeders are to run from the accumulator battery or the accumulator battery charging and discharging board to the automatic changeover switch without passing through any other distributor.

2.9.7 Fire doors

2.9.7.1 The power, control, indication and alarm systems of fire doors as required in Chapter II-2 of the SOLAS Convention in force are to be supplied by the emergency source of electrical power.

2.9.7.2 For passenger ships, an indicator to show whether each door operated by remote control is opened or closed is to be provided in the normally manned control station.

2.9.7.3 For passenger ships, the control and indication systems for the fire doors are to be designed on the fail-safe principle, provided with a release system having manual reset capable of being operated from either side of the door.

2.9.8 Watertight doors in passenger ships

2.9.8.1 The power circuit and its associated control, indication and alarm circuits for power-operated sliding watertight doors are to be supplied either directly by the emergency switchboard or by a dedicated distribution board connected with the emergency switchboard above the bulkhead deck.

2.9.8.2 Where a motor is provided for the opening and closing of the watertight doors, unless an independent reserve energy is provided, the power source is to be capable of being automatically changed over to the transitional source of emergency electrical power in the event of failure of either the main or the emergency source of electrical power. The capacity of the motor is to be sufficient to operate the watertight door at least three times, i.e. closed – open – closed.

2.9.8.3 A single electrical failure in the operating or control system of a power-operated sliding watertight door is not result in a closed door opening or interrupt any manual operation of the watertight door.

2.9.8.4 Availability of the power supply is to be continuously monitored at a point in the electrical circuit as near as practicable to the door operating equipment. Loss of any such power supply is to activate an audible and visual alarm at the central operating console on the navigation bridge.

2.9.8.5 Electrical power, control, indication and alarm circuits are to be protected against fault in such a way that a failure in one door circuit will not cause a failure in any other door circuit. Short circuits or other faults in the alarm or indicator circuits of a watertight door are not result in a loss of power operation of that door. Arrangements are to be such that leakage of water into the electrical equipment located below the bulkhead deck will not cause the door to open.

2.9.8.6 The enclosures of electrical components necessarily situated below the bulkhead deck are to provide suitable protection against the ingress of water as follows:

(1) electric motors, associated circuits and control components: IPX7;

(2) door position indicators and associated circuit components: IPX8.

Where the water pressure testing is to be based on the pressure that may occur at the location of the component during flooding for a period of 36 h;

(3) door movement warning signals: IPX6.

2.9.8.7 Electrical controls of watertight doors, including their cables, are to be kept as close as practicable

to the bulkhead in which the doors are fitted and so arranged as to minimize the likelihood of them being involved in any damage which the ship may sustain.

2.9.8.8 An audible alarm, distinct from any other alarm in the area, is to sound whenever the door is closed remotely by power and sound for at least 5 s but not more than 10 s before the door begins to move and is to continue sounding until the door is completely closed. In passenger areas and areas where ambient noise level exceeds 85 dB(A), the audible alarm is to be supplemented by an intermittent visual signal.

2.9.8.9 The central operating console is to be fitted on the navigation bridge, having a "master mode" switch with the following two modes of control:

(1) "Local control" mode for normal use, which is to allow any door to be locally opened and locally closed after use without automatic closure; and

(2) "Door closed" mode for emergency use, which is to automatically close any door that is opened while still permitting any door to be opened locally but with automatic reclosure upon release of the local control mechanism.

2.9.8.10 The central operating console at the navigation bridge is to be provided with a diagram showing the location of each door. Visual indicators showing whether the doors are open or closed are to be provided both on the central operating console and at hand operation positions above the bulkhead deck for watertight doors. A red light is to indicate a door is fully open and a green light is to indicate a door is fully closed. When the door is closed remotely, a red light is to indicate the intermediate position by flashing. The indicating circuit is to be independent of the control circuit for each door.

2.9.8.11 It is not to be possible to remotely open any watertight door from the central operating console.

2.9.9 Watertight access doors and hatch covers, etc. in cargo ships

2.9.9.1 For sliding watertight doors provided to ensure the watertight integrity of internal openings which are used while at sea, their operation, control and indicators are to comply with the following requirements:

(1) capable of being closed remotely at the navigation bridge and operated at either side of the bulkhead;

(2) an indicator to show whether the door is open or closed is to be provided in the control position;

(3) audible and visual alarms are to be given as the door is closed;

(4) each power-operated door is to be provided with an individual hand-operated mechanism, and it is to be possible to open and close the door by hand from each side.

2.9.9.2 Access doors and hatch covers normally closed at sea to ensure the watertight integrity of internal openings are to be provided with means of indication showing locally and on the navigation bridge whether these doors or hatch covers are open or closed.

2.9.9.3 All external openings leading to compartments assumed intact in the damage analysis, which are below the final damage waterline, except for cargo hatch covers, are to be fitted with indicators on the navigation bridge to show whether the openings are open or closed.

2.9.9.4 The electrical power, control, indication and audible and visual alarms required in 2.9.9.1 are to remain operable in the event of the failure of the main source of electrical power.

2.9.10 Boundary doors of special category spaces and ro-ro spaces

2.9.10.1 The requirements below are applicable to boundary doors of special category spaces or ro-ro spaces as defined in Chapter 9, PART TWO of the Rules. These spaces may be flooded through the doors. In cargo ships, where no part of a side shell door or stern door is under the highest waterline and the open area of the door is not greater than 6 m^2, the requirements from 2.9.10.2 to 2.9.10.5 of this Section are not applicable.

2.9.10.2 Separate indicator lights and audible alarms are to be provided on the navigation bridge and on each operating panel to show that the doors are closed and that their securing and locking devices are properly positioned.

The indication panel is to be provided with a lamp test function. It is not to be possible to turn off the indicator lights.

2.9.10.3 The indicator system is to be designed① on the fail-safe principle and is to show by a visual

---

① The indicator system is considered designed on the fail-safe principal when the following are provided:

a. The indication panel is provided with:
   – a power failure alarm;
   – an earth failure alarm;
   – a lamp test;
   – separate indication for door closed, door locked, door not closed and door not locked.

b. Limit switch electrically closed when the door is closed (when more limit switches are provided, they may be connected in series).

c. Limit switch electrically closed when securing arrangements are in place (when more limit switches are provided,

alarm if the door is not fully closed and not fully locked and by audible alarms if securing devices become open or locking devices become unsecured. The power supply for the indicator system is to be independent of the power supply for operating and closing the doors and is to be provided with a back-up power supply from the emergency source of electrical power or other secure power supply (e.g. UPS).
The sensors of the indicator system are to be protected from water, icing and mechanical damage.
2.9.10.4 The indication panel on the navigation bridge is to be equipped with a mode selection function "harbor/sea voyage", so arranged that an audible alarm is given on the navigation bridge if the vessel leaves harbor with the bow door or inner door not closed or with any of the securing devices not in the correct position.
2.9.10.5 For side shell doors or stern doors, a water leakage detection system① with audible alarm and television surveillance is to be arranged on passenger ships to provide an indication to the navigation bridge and to the engine control room of any leakage through the doors. A water leakage detection system② with audible alarm is to be arranged on cargo ships to provide an indication to the navigation bridge.
2.9.10.6 For inner doors, a water leakage detection system① with audible alarm and television surveillance is to be arranged to provide an indication to the navigation bridge and to the engine control room of leakage through the doors.
2.9.10.7 Between the bow door and the inner door a television surveillance system① is to be fitted with a monitor on the navigation bridge and in the engine control room. The system is to monitor the position of the doors and a sufficient number of their securing devices. Special consideration is to be given for the lighting and contrasting colour of objects under surveillance.
2.9.10.8 A drainage system① is to be arranged in the area between the bow door and ramp, or where no ramp is fitted, between the bow door and inner door. The system② is to be equipped with an audible alarm on the navigation bridge being set off when the water levels in these areas exceed 0.5 m or the high water level alarm threshold, whichever is lesser.
2.9.10.9 For ro-ro passenger ships, the special category spaces and ro-ro spaces are to be continuously patrolled or monitored by effective means (e.g. television surveillance) so that any movement of vehicles in adverse weather conditions, or unauthorized access by passengers thereto, will be detected whilst the ship is underway.

2.9.11 Emergency dumping system of dredgers and barges

2.9.11.1 For dredgers and hopper barges of which the operation draft is marked according to Section 13, Chapter 1, PART TWO of the Rules, emergency devices, controlled from the navigating bridge, are to be fitted so that the discharge of spoil is possible in case of failure of the main electric power supply or the main hydraulic unit and/or a single failure of the normal control systems.

Section 10 HEATING AND COOKING EQUIPMENT

2.10.1 General requirements

2.10.1.1 All electric space heaters are to be installed permanently.
2.10.1.2 Heating appliances are not to be installed in positions where combustible gases and dusts are likely to accumulate.
2.10.1.3 Heating appliances are to be so mounted that there will be no risk of excessive heating of adjacent decks, bulkheads or other surroundings.

2.10.2 Control and installation of heating and cooking equipment

2.10.2.1 Each item of heating or cooking equipment is to be controlled as a complete unit by a multi-pole linked switch mounted in the vicinity of the equipment. In the case of cabin heaters, a single-pole switch will be acceptable.

2.10.3 Supply of heating equipment

2.10.3.1 Each heater is to be connected to a separate final sub-circuit for heating except that up to ten

---

they may be connected in series).

d. Two electrical circuits (also in one multicore cable), one for the indication of door closed/not closed and the other for door locked/not locked.
e. In the case of dislocation of limit switches, indication to show: not closed/not locked/securing arrangement not in place, as appropriate.

① The system is to be designed on the fail-safe principle, see footnote of 2.9.10.3 of this Section.

small heaters of total connected current rating not exceeding 16 A may be connected to a single final sub-circuit for heating.

Section 11 STORAGE BATTERIES

2.11.1 Arrangement and installation

2.11.1.1 Storage batteries are not to be installed in spaces where they are exposed to excessively high or low temperatures, water splattering, steam or other factors which will impair their serviceability or shorten their service life. They are to be installed in such a way that persons will not be endangered and equipment will not be damaged by escaping gases or electrolytic leakage.

2.11.1.2 Storage batteries are to be so installed as to ensure accessibility for replacing cells, inspection, testing, topping-up and cleaning.

2.11.1.3 Storage batteries are not to be installed in the accommodation area. An exception may be granted for gastight cells, where charging does not result in the development of harmful gases.

2.11.1.4 Suitable protection measures are to be provided where the storage batteries are exposed to the risk of mechanical damage or falling objects.

2.11.1.5 Storage batteries connected to a charging device with a power output① of more than 2 kW are to be housed in a room assigned to the batteries only, or in a box or a locker on open deck.

2.11.1.6 Storage batteries connected to a charging device with a power output of 0.2 kW to 2 kW are to be installed in accordance with 2.11.1.5. They also may be installed in a box or a locker within a suitable space, or may be installed in an open position in a well ventilated machinery space.

2.11.1.7 Storage batteries connected to a charging device with a power output of less than 0.2 kW may be installed in an open position or in a battery box in any suitable space.

2.11.1.8 A gap of more than 20 mm is to be provided around each battery, and non-hygroscopic and electrolyte-resistant insulating material is to be used for the separation, dunnage and fixing of the battery. Measures are to be taken to prevent any leaking electrolyte from entering in contact with the ship's structure.

2.11.1.9 Any surface of dedicated battery rooms, boxes, lockers and associated ventilation ducts, etc., liable to corrosion, by the electrolyte or by the gas escaped from the electrolyte, are to be protected against corrosion.

2.11.1.10 Prime mover starter batteries are to be installed as close as practicable to the primer mover served.

2.11.1.11 Storage batteries used as emergency and temporary emergency source of electrical power are to be installed in accordance with the requirements of 2.2.1.2 of this PART.

2.11.1.12 A warning notice of "NO SMOKING OR NAKED LIGHTS" is to be displayed adjacent to doors of battery rooms and covers of battery boxes or lockers.

2.11.2 Ventilation

2.11.2.1 Battery rooms, boxes and lockers are to be ventilated to prevent the accumulation of flammable gases.

2.11.2.2 Natural ventilation may be employed if the required number of air changes is small and the duct can be run directly from the top of the battery room, box or locker to the open air above, with no part of the duct more than 45° from the vertical.

2.11.2.3 For natural ventilation of the battery room, the cross-sectional area A of the inlet is to be equal to that of the outlet, not less than:

(1) for vented type batteries

$$A = \frac{50 \times U_n \times Q \times n}{1000} \quad \text{cm}^2$$

(2) for valve-regulated sealed batteries

$$A = \frac{20 \times U_n \times Q \times n}{1000} \quad \text{cm}^2$$

where: U_n — nominal voltage of the battery, in V;

Q — battery capacity, in Ah;

n — number of cells in series.

2.11.2.4 Mechanical ventilation is to be provided for the battery room, box or locker containing vented

---

① Power output of the charging device is to be calculated from the maximum charging current multiplied by the rated voltage of batteries.

type batteries with a total charging power higher than 2 kW.

2.11.2.5 Except those boxes and lockers on open deck or within the spaces required in 2.11.1.6 and 2.11.1.7 of this Section, the ventilation system for battery rooms, boxes or lockers is to be separate from other ventilating systems. The exhaust ducting is to be led to a location where any flammable gas can be safely diluted, away from any source of ignition, and the inlet ducting is to be led into spaces where flammable gases may accumulate. The outlet is to be situated at the top and the inlet at the bottom with the means to prevent the ingress of water and flame.

2.11.2.6 Mechanical ventilators for battery rooms, boxes or lockers are to be provided with means to prevent sparking in case of the impeller touching the casing. Non-metal impellers are to be of an antistatic material.

2.11.2.7 All openings of battery rooms, other than ventilation openings, are to be effectively sealed to prevent the explosive gas from entering adjacent compartments.

2.11.2.8 The quantity Q of air expelled from the rooms, boxes or lockers containing vented type batteries is not to be less than:

$$Q = 0.11\ In \quad m^3/h$$

where: I — the maximum charging current during the development of gas, but not less than 25% of the maximum charging current output by the charging device, in A;

n — number of battery cells.

2.11.2.9 The quantity of air expelled from the rooms, boxes or lockers containing valve-regulated sealed batteries may be reduced to 25% of that required in 2.11.2.8.

2.11.3 Charging facilities

2.11.3.1 Charging facilities are to be provided for all storage batteries such that the completely discharged battery can be recharged to the rated capacity in not more than 10 h, having regard to the service requirements.

2.11.3.2 Suitable means are to be provided for controlling and monitoring charging of storage batteries, and to protect them in accordance with the requirements of 2.5.12.2 of this PART.

2.11.3.3 For floating circuits or any other conditions where the load is connected to the storage battery whilst it is on charge, the maximum battery voltage is not to exceed the safe value for any connected apparatus.

2.11.4 Electrical equipment

2.11.4.1 The installation of electrical equipment is to be avoided in battery rooms. Where this is necessary, the explosion-proof electrical equipment required in 1.3.3.3 of this PART is to be selected.

2.11.5 Recording of the type, location and maintenance cycle of batteries

2.11.5.1 A schedule of batteries used for essential and emergency services is to be compiled and maintained. The schedule, which is to be reviewed by the ISC attending Surveyor, is to include at least the following information regarding the batteries:

— type and manufacturer's type designation;
— voltage and ampere-hour rating;
— location;
— equipment and/or system(s) served;
— maintenance/replacement cycle dates;
— date(s) of last maintenance and/or replacement;
— for replacement batteries in storage, the date of manufacture and shelf life.

2.11.5.2 Procedures are to be put in place to ensure that, where batteries are replaced, they are of an equivalent performance type.

2.11.5.3 Where valve-regulated sealed batteries are replaced by vented type batteries, it is to be ensured that there is adequate ventilation as so required in 2.11.2.4 and 2.11.2.8 of this Section, and that the requirements in 2.11.1 of this Section relevant to the location and installation of vented type batteries are complied with.

2.11.5.4 Details of the schedule reviewed by the Surveyor and of the procedures, as mentioned above, are to be included in the ship's safety management system. Details of the schedule and of the procedures are to be integrated into the ship's operational maintenance routine as appropriate and be inspected at appropriate intervals, and to be verified by the surveyor.

Section 12 CABLES

2.12.1 General requirements

2.12.1.1 Cables are to be selected according to the environmental conditions of the space where the cables will be installed, methods of installation, rated current, duty, diversity factor, etc.

2.12.1.2 The rated voltage of any cable is not to be lower than the nominal voltage of the circuit for which it is used.

2.12.1.3 Portable electrical equipment is to be provided with movable flexible cables.

2.12.1.4 Cables used in the non-earthing system are to be provided with suitable rating so as to sustain the additional stress of the cable insulation in the event of failure.

2.12.2 Choice of insulating material and voltage rating

2.12.2.1 The rated maximum operating temperature of the insulating material is to be at least 10℃ higher than the maximum ambient temperature liable to be produced in the space where the cable is installed.

2.12.2.2 The insulating material of cables is generally to be selected in accordance with Table 2.12.2.2. The selection of other insulating materials is to comply with IEC publication 60092.

Maximum Rated Conductor Temperature of Insulating Material Table 2.12.2.2

Insulating material	Abbrev.	Max. rated conductor temp. (℃)	
		Normal operation	Short circuit
Ethylene propylene rubber	EPR	90	250
High modulus or hard grade ethylene propylene rubber	HEPR	90	250
Cross-linked polyethylene	XLPE	90	250
Silicone rubber	S95	95②	350①
Cross-linked polyolefin material for halogen-free cables	HF90	90	250

Notes: ① Applicable only to power cables and not appropriate for tinned copper conductors.

② The maximum rated conductor temperature for silicone rubber is 180℃, but the practical maximum working temperature is limited by the sheathing materials.

2.12.2.3 The rated voltage of a cable is expressed in U_0/U, where U_0 is the rated power voltage between conductor and "earth" (or metallic screen or surrounding medium of cables) and U is the rated power voltage between conductors. The choice of rated voltage of the cables depends on the system voltage and the system earthing arrangements, which is not to be lower than that given in Table 2.12.2.3.

Choice of Rated Voltage of Cables for AC Systems Table 2.12.2.3

Rated (between phases) voltage (kV) of Systems	Rated voltage U_0/U (kV) of cables	
	Category I distribution system	Category II distribution system
≤0.25	0.15/0.25	0.15/0.25
≤1.0	0.6/1.0	0.6/1.0
≤3.0 (3.3)	1.8/3.0	3.6/6.0
≤6.0 (6.6)	3.6/6.0	6.0/10.0
≤10.0 (11)	6.0/10.0	8.7/15.0

Notes:

① Category I distribution system: Protective devices are to be provided to automatically disconnect the circuits having earth faults.

② Category II distribution system: In AC insulation systems or in AC systems with high-resistance earthed neutral, circuits having earth faults are not to be automatically disconnected.

2.12.3 Choice of protective covering

2.12.3.1 Cables are to be provided with appropriate sheath that satisfies the fluid resistance requirements according to their installation locations. For example, cables permanently fitted on decks exposed to the weather, in bathrooms, cargo holds, refrigerated spaces, machinery spaces or in any other location where water condensation or harmful vapour (e.g. oil vapour) may be present are to have an impervious sheath. The nature of the impervious sheath is to satisfy the requirements for environmental conditions.

2.12.3.2 When choosing different types of protective coverings, consideration is to be given to the mechanical actions to which each cable may be subjected during installation and in service. If the mechanical strength of the protective covering is considered insufficient, the cable is to be fitted in pipes or

conduits or trunking or otherwise protected.

2.12.3.3 All cables and wiring external to electrical equipment are to be at least of a flame-retardant type. In general, cables which have passed the test of bunched flame-retardant cables in accordance with acceptable standards① are to be used. Where cables which have individually passed the test of a single flame-retardant cable in accordance with acceptable standards② are to be bunched, means are to be provided to limit the propagation of fire along the bunched cables (see 2.12.10).

2.12.3.4 Where cables for services, required to be operable under fire conditions, including their supply cables, pass through high fire risk areas③, and in addition for passenger ships, main vertical fire zones, other than those which they serve, they are to be so arranged that a fire in any of these areas or zones does not affect the operation of the service in any other area or zone. This may be achieved by either of the following:

(1) Cables being of a fire resistant type④ complying with the requirements of 3.5.1.1 of this PART are installed and run continuously to keep the fire integrity within the high fire risk area, as shown in Figure 2.12.3.4.

(2) At least two-loops/radial distributions run as widely apart as is practicable and so arranged that in the event of damage by fire at least one of the loops/radial distributions remains operational.

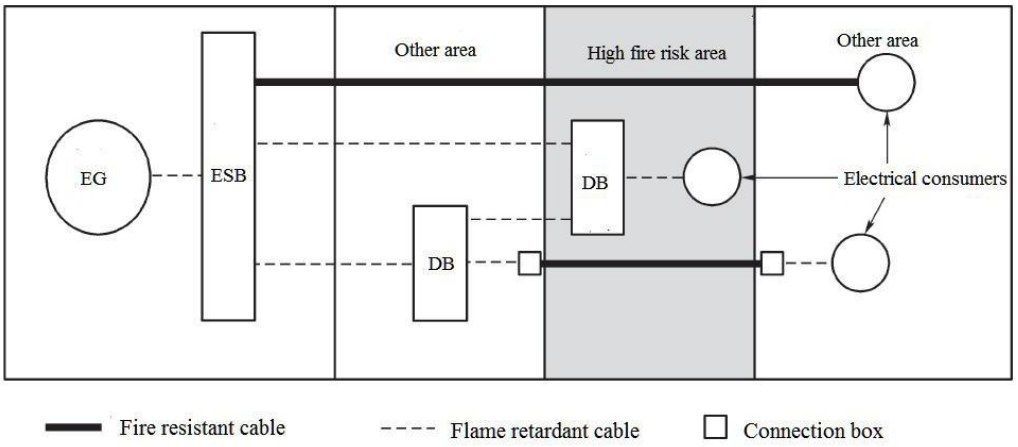


Figure 2.12.3.4 Cables for Services under Fire Conditions

2.12.3.5 Services required to be operable under fire conditions include:

(1) general emergency alarm system;
(2) fire detection and fire alarm system;
(3) fire extinguishing system and fire extinguishing medium release alarm;
(4) public address system;
(5) control and power systems of power operated fire doors and status indication systems for all fire doors;
(6) control and power systems of power operated watertight doors and their status indication systems;
(7) emergency lighting;
(8) low location lighting;
(9) remote emergency stop/shutdown arrangements for systems which may support the propagation of fire and/or explosion;
(10) emergency fire pump.

---

① Refer to IEC Publication 60332-3-22: Tests on electric and optical fibre cables under fire conditions – Part 3-22: Test for vertical flame spread of vertically-mounted bunched wires or cables – Category A, or the equivalent standards.

② Refer to IEC Publication 60332-1-2: Tests on electric and optical fibre cables under fire conditions – Part 1-2: Test for vertical flame propagation for a single insulated wire or cable – Procedure for 1 kW pre-mixed flame and IEC 60332-2-2: Tests on electric and optical fibre cables under fire conditions – Part 2-2: Test for vertical flame propagation for a single small insulated wire or cable – Procedure for diffusion flame, or the equivalent standards.

③ The "high fire risk areas" are defined as follows:
(1) machinery spaces as defined in SOLAS Reg. II-2/3.30, excluding spaces having little or no fire risk as defined in SOLAS Reg. II-2/9.2.2.3.2.2 (10) (including the interpretations for tables 9.3, 9.4, 9.5, 9.6, 9.7 and 9.8 given in MSC/Circ.1120 as amended by MSC.1/Circ.1436 and MSC.1/Circ.1510);
(2) spaces containing fuel treatment equipment or other highly flammable substances;
(3) galley and pantries containing cooking appliances;
(4) laundry containing drying equipment;
(5) spaces as defined in SOLAS Reg. II-2/9.2.2.3.2.2(8), (12), and (14) for ships carrying more than 36 passengers.

④ Fire resistant type cables are to be easily distinguishable.

2.12.3.6 The electrical cables to the emergency fire pump are not to pass through the machinery spaces containing the main fire pumps and their source(s) of power and/or prime mover(s). When cables pass through high fire risk areas, the cables are to be of a fire resistant type.
2.12.3.7 Where necessary for particular applications, ISC may permit the use of special types of cables which do not comply with the requirements of 2.13.3.3 of this Section, such as radio frequency cables or digital computer information transmission system cables.
2.12.3.8 In passenger spaces and in service areas only halogen-free cables are to be used.

2.12.4 Determination of the cross-sectional area of conductors

2.12.4.1 The maximum continuous load carried by a cable is not to exceed its current rating corrected by correction factors. The diversity factor of the individual loads and the duration of the maximum load may be taken into account in estimating the maximum continuous load.
2.12.4.2 Cables supplying cargo winches, revolving cranes, windlasses and capstans are to be suitably rated for their duty.
2.12.4.3 The cross-sectional area of the conductors of equalizer leads for DC generators is not to be less than 50% of that of the main circuit cables. The cross-sectional area of neutral conductors in three-phase four-wire distribution systems is to be equal to at least 50% of that of phase conductors. If the cross-sectional area of phase conductors is 16 mm^2 or less, the cross-sectional area of the neutral conductors is to be the same.

2.12.5 Continuous service current rating

2.12.5.1 The maximum continuous load carried by a cable is not to exceed the values as given in Table 2.12.5.1.
Where a more precise evaluation of current rating has been carried out based on empirical or calculated data, details may be submitted to ISC for approval.

Current Ratings for Cables during Continuous Working Time
(Based on Ambient Temperature of 45℃) (A) **Table 2.12.5.1**

Nominal cross-section	Maximum rated conductor temp 90℃			Maximum rated conductor temp 95℃		
mm^2	Single core	2 cores	3 or 4 cores	Single core	2 cores	3 or 4 cores
1	18	15	13	20	17	14
1.5	23	20	16	26	22	18
2.5	30	26	21	32	27	22
4	40	34	28	43	37	30
6	52	44	36	55	47	39
10	72	61	50	76	65	53
16	96	82	67	102	87	71
25	127	108	89	135	115	95
35	157	133	110	166	141	116
50	196	167	137	208	177	146
70	242	206	169	256	218	179
95	293	249	205	310	264	217
120	339	288	237	359	305	251
150	389	331	272	412	350	288
185	444	377	311	470	400	329
240	522	444	365	553	470	387
300	601	511	421	636	541	445

2.12.5.2 The continuous service of cables required in this Section is the service that the continuous service period of current with constant loading are three times longer than the time constant of cables, i.e. more than the critical duration (see Figure 2.12.5.2).

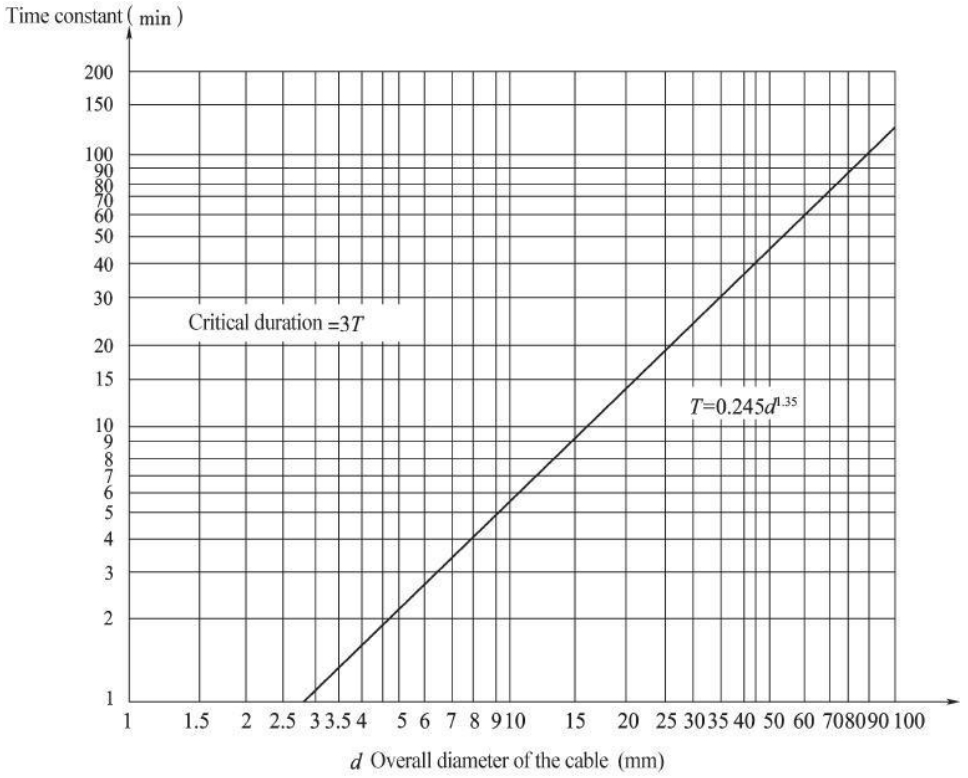

Figure 2.12.5.2 Time Constant of Cables

2.12.6 Correction factors for current rating

2.12.6.1 Correction factors for different ambient temperatures.

When it is known that the ambient temperature is different from 45℃, correction factors given in Table 2.12.6.1 are to be applied.

Correction Factor for Ambient Temperature **Table 2.12.6.1**

Ambient temp. (℃) / Max. operating conductor temp. (℃)	35	40	45	50	55	60	65	70	75	80	85
60	1.29	1.15	1.00	0.82	–	–	–	–	–	–	–
65	1.22	1.12	1.00	0.87	0.71	–	–	–	–	–	–
70	1.18	1.10	1.00	0.89	0.77	0.63	–	–	–	–	–
75	1.15	1.08	1.00	0.91	0.82	0.71	0.58	–	–	–	–
80	1.13	1.07	1.00	0.93	0.85	0.76	0.65	0.53	–	–	–
85	1.12	1.06	1.00	0.94	0.87	0.79	0.71	0.61	0.50	–	–
90	1.10	1.05	1.00	0.94	0.88	0.82	0.74	0.67	0.58	0.47	–
95	1.10	1.05	1.00	0.95	0.89	0.84	0.77	0.71	0.63	0.55	0.45

2.12.6.2 Correction factors for bunched cables

(1) For cables laid in one of the following manners and so arranged as to ensure free circulation of cooling air around each bunch, the current ratings in Table 2.12.5.1 may be directly applied:

① not more than six cables bunched together on cable trays, in cable conduits, pipes or trunking;

② more than six cables arranged in the following manners:

distance between any two sextuplets is at least equal to the diameter of the thickest cable

○○○○○○ ○○○○○○ ○○○○○○

or distance between any two triplets both horizontally and vertically is at least equal to the diameter of the thickest cable

○○○ ○○○ ○○○

○○○ ○○○ ○○○

(2) Where more than six cables, which may be expected to operate simultaneously at their rated capacity, are laid close together in a cable bunch[①] in such a way that there is an absence of free air circulation around

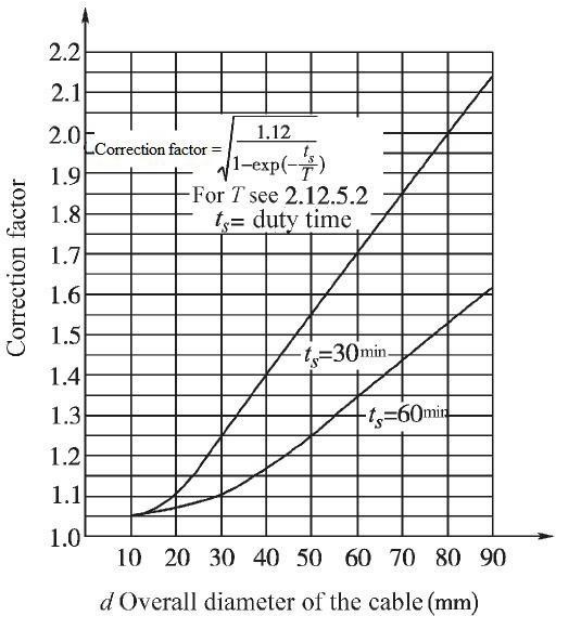
① Cables are said to be bunched when two or more are contained within a single conduit, trunking or duct, or if not enclosed, are not separated from each other.

them, a correction factor of 0.85 is to be applied. When a corrector factor of 0.85 is used, care is to be taken that there are in general not more than two layers in each cable bunch.

2.12.6.3 Correction factors for non-continuous service

(1) For half-hour and one-hour services, the corresponding correction factors given by Figure 2.12.6.3(1) may be applied. These correction factors are applicable only if the periods of no load are longer than the critical duration given in Figure 2.12.5.2.

(2) For repetitive short-time services, the corresponding correction factors given in Figure 2.12.6.3(2) may be applied.



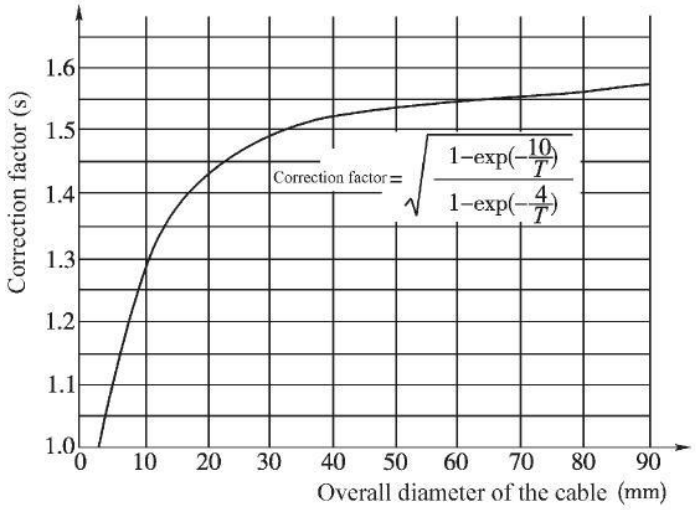


Figure 2.12.6.3(1) Correction Factors for Half-Hour and One-Hour Services

Note: The correction factors given in the Figure are roughly calculated for periods of 10 min, with a constant load for 4 min and without load for 6 min.

Figure 2.12.6.3(2) Correction Factors for Repetitive Short-Time Services

2.12.7 Parallel connection of cables

2.12.7.1 Parallel connection of cables will be permitted only for cables having a cross section of 10 mm^2 or more. The current rating of cables connected in parallel is the sum of the current ratings of all parallel conductors provided the cables have equal impedance, cross section and rated maximum operating conductor temperature.

2.12.8 Short-circuit capacity

2.12.8.1 Cables and their insulated conductors are to be capable of withstanding the mechanical and thermal effects of the maximum short-circuit.

2.12.9 Cable runs

2.12.9.1 Cable runs are to be, as far as possible, straight and accessible for inspection.

2.12.9.2 Cable runs are to be so arranged as to avoid the harmful effects from moisture or condensed water.

2.12.9.3 Cable runs are to be, as far as possible, away from the sources of heat such as boilers, hot pipes, resistors, etc., and are to be protected against mechanical damage.

2.12.9.4 Cables are not to be installed across expansion joints in any structure. Where this is unavoidable, a loop of cable having a length sufficient to accommodate the expansion of the joint is to be provided. The internal radius of the loop is to be at least 12 times the external diameter of the cable.

2.12.9.5 Cables having insulating materials with different maximum rated conductor temperatures are not to be bunched together. Where this is unavoidable, the cables are to be so installed that no cable reaches a temperature higher than that permitted for the cable with the lowest temperature rating in the bunch.

2.12.9.6 Cables having a protective covering or sheathing which may damage the covering or sheathing of other cables are not to be bunched together.

2.12.9.7 Where the main bus-bar is subdivided into two or more independent sections in accordance with the requirements of 2.1.1.1(5) of this Chapter, cables from different main generators to main switchboards are to follow at least two routes which are to be as far apart as practicable, for example from port and starboard or from different deck platforms.

2.12.9.8 Where a duplicate supply is required for essential electrical equipment, such as the two cables for the supply of the control box of navigation lights, the two cables are to follow different routes which are to be as far apart as practicable, both vertically and horizontally.

2.12.9.9 In the case of duplicated essential services, or systems which could operate as each other's stand-by for an essential function (such as duplicated power equipment of steering gears), the supply and any associated control cables are to follow different routes which are to be as far apart as practicable, both vertically and horizontally.

2.12.9.10 In passenger ships, distribution systems are to be so arranged that fire in any main vertical zone as defined in PART SIX of the Rules will not interfere with supply to services essential for safety in any other such zone. The requirement is considered satisfied if main and emergency feeders passing through any such zone are separated both vertically and horizontally as widely as is practicable.

2.12.9.11 Cables serving essential services or emergency power equipment, emergency lighting and internal communications or signals used in an emergency are to be as far as practicable routed clear of galleys, laundries, machinery spaces and their casings and other high fire risk areas, except for supplying equipment in these spaces.

Where possible, these cables are to be run in such a manner as to preclude their being rendered unserviceable by heating of the bulkheads that may be caused by a fire in an adjacent space.

2.12.9.12 Main cable runs and cables for the supply and control of essential services are to be kept away from the machinery and machinery parts① having an increased fire risk unless:

(1) the cables serve such installations;

(2) the cables are separated by a steel bulkhead or deck from such installations;

(3) the cables are of a fire-resisting type.

2.12.9.13 Where trunk cables are laid in concealed manner, the panelling in way of which is to be arranged for easy removal.

2.12.9.14 Cables are not to be directly embedded in the thermal or sound insulation made of combustible material. Where cables are separated by non-combustible covering, they may be laid in the insulation, but the load carried is to be reduced accordingly.

2.12.9.15 The arrangement and run of fire resistant cables are to be in compliance with the following:

(1) Cables are to be so arranged that the loss of these services due to a localized fire at any one area or zone specified in 2.12.3.4 of this Section is minimized.

(2) Cables are to be run as straight as is practicable.

2.12.9.16 Cables of intrinsically safe circuits are to be laid apart from those for non-intrinsically safe circuits, e.g. neither bundled together or placed in the same casing or pipe, nor fixed by common clamps. The outer sheath of the cable is to be coloured blue or alternatively black with clearly visible blue stripes. Intrinsically safe circuits of "ia" and "ib" class are not to be run in the same cable and to have their own separate cables.

2.12.10 Means to limit the propagation of fire along bunched cables

2.12.10.1 Where cables which have individually passed the test of a single flame-retardant cable in

① Machinery, machinery parts or equipment containing combustibles are considered to have an increased fire risk.

accordance with acceptable standards (see 2.12.3.3) are to be bunched, means are to be provided to limit the propagation of fire along the bunched cables[①], as required in 2.12.10.2 to 2.12.10.4.

2.12.10.2 Fire dampers are to be provided (see Figure 2.12.10.2).

(1) Cables laid vertically in enclosed or semi-enclosed spaces are to be provided with fire dampers in the following locations:

① at every second deck or approximately 6 m, except cables installed within the fully-closed trunking;

② at cable entrances of main switchboard and emergency switchboard;

③ at cable entrances of engine control room;

④ at cable entrances of centralized control panels for propulsion machinery and essential auxiliary machinery;

⑤ at each end of the fully-closed cable duct.

(2) Cables laid horizontally in closed or semi-enclosed spaces are to be provided with fire dampers in the same locations required in (1), but the maximum spacing of fire dampers may be increased to 14 m.

(3) In the passageways having a height lower than the neck of a standing person within cargo holds and cargo areas, fire dampers can only be fitted on the boundaries of compartments.

2.12.10.3 The fire dampers are to be designed to meet the following requirements:

(1) The fire resistance of cables passing through fire stops must meet the requirements for class B-0 divisions.

(2) Fire dampers are to be made of steel plate with the thickness of at least 3 mm.

(3) Where cables are laid vertically in the non-fully-closed trunking, the fire damper is to cover the sectional area of the trunking.

(4) Where cables are laid open, the fire damper is to extend around to twice the maximum laying size of cables, but not to penetrate ceilings, decks, bulkheads or the rigid sidewall of trunking.

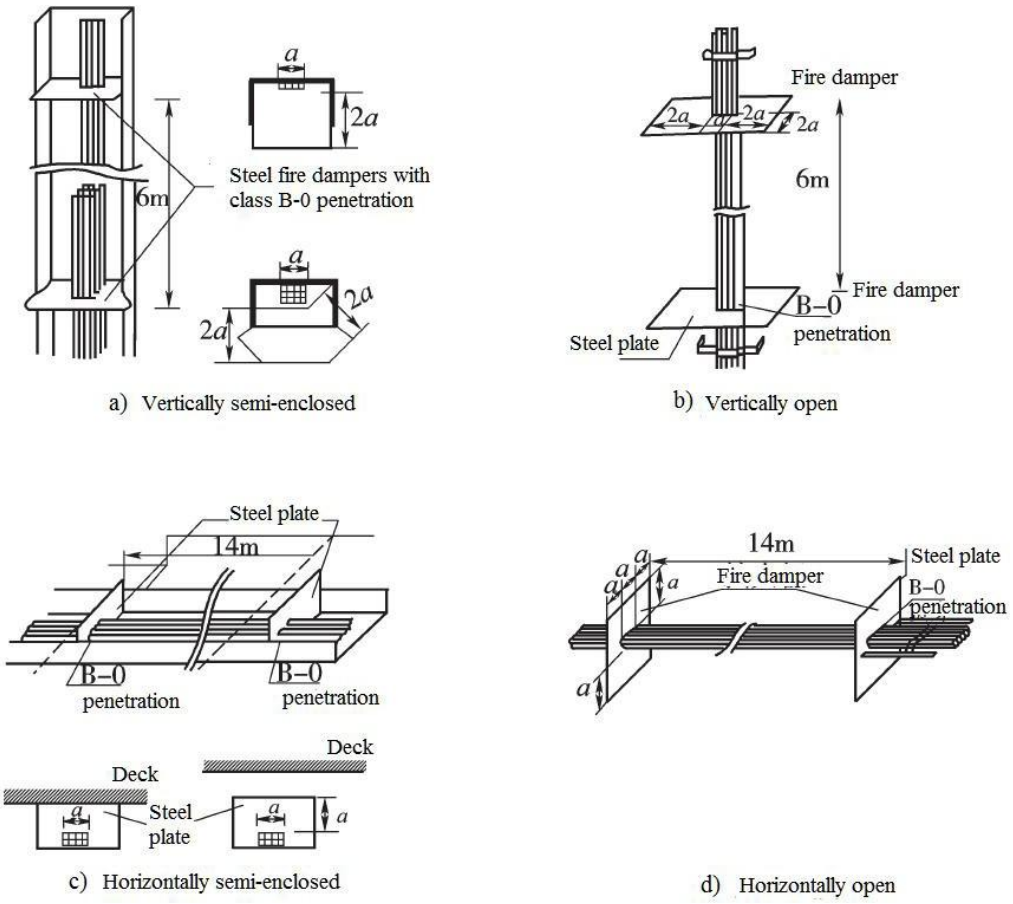

Figure 2.12.10.2 Locations of Fire Dampers

2.12.10.4 Instead of the fire dampers required above, installed cable bunches may be provided with

① The bunched cables mentioned here are 5 or more cables from machinery spaces and high fire hazard spaces and more than 10 cables from other spaces are laid close together in the cable trunking.

flameproof coating:
(1) over a length of 1 m in every 14 m for horizontal cable runs (see Figure 2.12.10.4a);
(2) over the entire length of vertical cable runs (see Figure 2.12.10.4b).

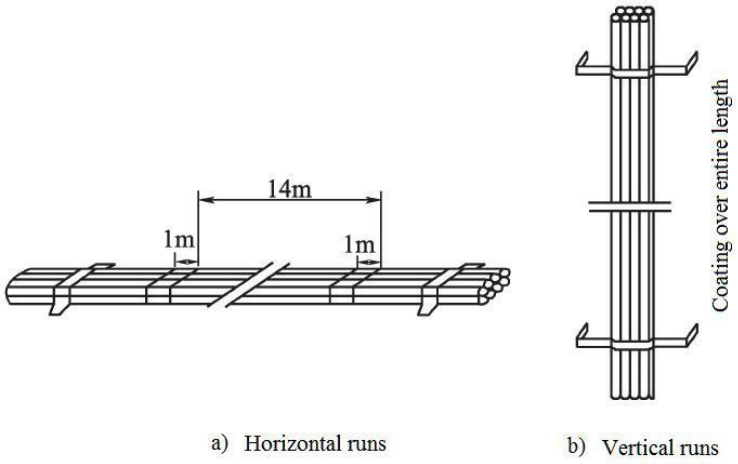

Figure 2.12.10.4 Location of Flameproof Coating

2.12.11 Mechanical protection of cables

2.12.11.1 Cables exposed to risk of mechanical damage are to be protected by metal channels or casings or enclosed in steel conduits, unless the protective sheathing of cables is sufficient to withstand the possible damage.

2.12.11.2 Cables in cargo holds and other spaces where there is exceptional risk of mechanical damage are to be suitably protected, even if armoured.

2.12.11.3 Metal casings for mechanical protection of cables are to be efficiently protected against corrosion.

2.12.11.4 Where cables are placed underneath the floor plates in machinery spaces, reliable precautions are to be taken to prevent such cables from being soaked in oil or water, or being exposed to mechanical damage.

2.12.12 Radius of bend

2.12.12.1 The minimum internal radius of bend of installed cables is to be generally in accordance with the manufacturer's recommendations, and is not to be less than the provisions of Table 2.12.12.1(1) and Table 2.12.12.1(2).

Minimum Internal Radius of Bends in Cables Rated up to 1.8/3kV Table 2.12.12.1(1)

Cable construction		Overall diameter of cable *D* (mm)	Minimum internal radius of bend *F*
Insulation	Outer covering		
Thermoset material (circular copper conductor)	Not armoured or not braided	≤ 25	4*D*
		> 25	6*D*
	Metal sheathed, braided or armoured	Any	6*D*
	Metal thread armoured, metal strip armoured	Any	6*D*
	Synthetic polyester/metal sheathed slice or combined sheathed	Any	8*D*
Thermoset material (circular copper conductor)	Any	Any	8*D*

Minimum Internal Radius of Bends in Cables Rated at 3.6/6.0(7.2) kV and above
Table 2.12.12.1(2)

Cable construction	Overall diameter of cable *D* (mm)	Minimum internal radius of bend *F*
Single core cable	Any	12*D*
3-core cable	Any	9*D*

2.12.13 Securing of cables

2.12.13.1 Cables are to be effectively supported and secured with the exception of cables for portable appliances and of those installed in pipes, conduits, trunking or special casings.

2.12.13.2 Clips or straps are to be robust and are to have a sufficient surface area and a certain shape so that the cables may remain tight without their covering or sheathing being damaged.

2.12.13.3 Clips, supports and accessories are to be made of corrosion-resistant material or suitably corrosion inhibited before erection.

2.12.13.4 The distance between supports is to be suitably chosen according to the type of cables and the possible vibration, and is generally to be in accordance with Table 2.12.13.4.

External Diameter of Cable and Distance between Supports Table 2.12.13.4

External diameter of cable (mm)		Distance between supports (mm)	
Exceeding	Not exceeding	Non-armoured cables	Armoured cables
–	8	200	250
8	13	250	300
13	20	300	350
20	30	350	400
30	–	400	450

2.12.13.5 When cables are fixed by means of non-metallic clips or straps, and are not laid on top of horizontal cable trays or supports, suitable metal cable clips or straps are to be added at regular distances not greater than 1 m in order that in the event of a fire, cables are prevented from falling and causing an injury to personnel or an obstruction to any escape route.

2.12.14 Penetration of bulkheads and decks by cables

2.12.14.1 Penetration of watertight bulkheads or decks may be carried out with either individual watertight glands or with packed watertight boxes carrying several cables, provided that the watertight integrity of the bulkheads or decks is to be maintained.

2.12.14.2 Where cables pass through non-watertight bulkheads or structural steel, the holes are to be bushed with suitable material.

If the steel is 6 mm or more in thickness, adequately rounded edges may be accepted as the equivalent of bushing.

2.12.14.3 Penetration of bulkheads and decks requiring a certain fire integrity is to be so effected as to ensure that the required fire integrity is not impaired.

2.12.14.4 Cables passing through decks are to be protected by deck tubes or ducts having a suitable height.

2.12.14.5 Materials used for glands and bushings are to be such that there is no risk of corrosion to cables or hull structures.

2.12.14.6 Where rectangular holes are cut in bulkheads or structural steel, the corners of the holes are to be radiused.

2.12.14.7 Where a cable transit seal system is used, a register is to be developed according to Appendix 3, Chapter 4, PART ONE of the Rules.

2.12.15 Installation of cables in pipes, conduits or trunking

2.12.15.1 When cables are installed in metal pipes, conduits or trunking, the following requirements are to be complied with:

(1) The internal surfaces of the pipes, conduits or trunking are to be smooth and protected against corrosion.

(2) Provision is to be made at the ends of pipes, conduits or trunking so as to protect the sheathing or covering of cables from being damaged.

(3) The internal sectional area and radius of bend of pipes or conduits are to be such as to permit easy drawing in and out the cables contained therein; the internal radius of bend of pipes or conduits is not to be less than that allowed for cables, provided that for pipes equal to or above 63 mm in external diameter, the internal radius of bend is not less than twice the external diameter of the pipe.

(4) The drawing-in factor (ratio of the sum of the cross-sectional areas of the cables to the internal cross-sectional area of the pipe) is not to exceed 0.4.

(5) Pipes, conduits or trunking are to be effectively earthed.

(6) Pipes, conduits or trunking are to be so arranged that water will not accumulate inside them (consideration being given to possible condensation).

(7) If necessary, ventilation openings are to be provided, preferably at the highest and lowest points, so as

to permit air circulation and to prevent possible accumulation of water at any part of the pipes, conduits or trunking. This may be done only if the fire risk will not be increased thereby.
(8) Expansion joints are to be provided where necessary for long pipe run.
2.12.15.2 Where cables are laid in trunks, the trunks are to be so constructed as not to afford passage for fire from one 'tween deck or compartment to another.
2.12.15.3 Cables used for cold cathode luminous discharge lamps are not to be installed in metal conduits unless protected by metal screen.

2.12.16 Installation of cables in refrigerated spaces
2.12.16.1 Cables not serving refrigerated spaces are not to pass through such spaces. Cables installed in refrigerated spaces are to have an impervious sheath and are to be protected against mechanical damage. If an armoured cable is used, the armour is to be protected against corrosion by a further moisture-resisting covering.
2.12.16.2 Cables are to be run in the open in refrigerated spaces.
2.12.16.3 Metal supports used for securing the cables are to be galvanized or otherwise protected against corrosion.

2.12.17 Relief of tension
2.12.17.1 Cables are to be so installed that the tension stress applied to them either by their own weight or for any other reason is minimized. This is particularly important for cables of small cross-sections and for cables laid vertically or in vertical pipes.

2.12.18 Electrodynamic forces
2.12.18.1 In order to guard against the effects of electrodynamic forces in the event of short-circuit, single-core cables are to be firmly fixed and the strength of supports is to be sufficient to withstand the electrodynamic forces corresponding to the prospective short-circuit currents.

2.12.19 Installation of single-core cables for alternating current
2.12.19.1 For AC power systems, two-core or multi-core cables are to be used as far as practicable. Where it is necessary to use single-core cables for circuits rated in excess of 20 A, the following requirements are to be complied with:
(1) Cables are to be either non-armoured or armoured and covered with non-magnetic material.
(2) Cables belonging to the same circuit are to be contained in the same pipe, conduit or trunking. Cable clips are to include cables of all phases of a circuit, unless the clips are of non-magnetic material.
(3) In the installation of two, three or four single-core cables forming respectively single-phase, three-phase, or three-phase four-wire circuits, the cables are to be as far as possible in contact with one another. In any event, the distance between adjacent cables is not to be greater than one cable diameter.
(4) When it is necessary to install single-core cables of current rating greater than 250 A near a steel bulkhead, the clearance between the cables and the bulkhead is to be at least 50 mm, unless the single-core cables belonging to different phases are installed in trefoil formation.
(5) Magnetic material is not to be placed between single-core cables of a group for the same circuit. Where cables pass through steel plates, all conductors of the same circuit are to pass through a plate or gland so constructed that there is no magnetic material between the cables, and the clearance between the cables and the magnetic material is not to be less than 75 mm, unless single-core cables belonging to different phases are installed in trefoil formation.
(6) In order to equalize to some degree the impedance of three-phase circuits of considerable length consisting of single-core cables having a cross sectional area of 185 mm^2 or over, the phases are to be transposed at regular intervals of not exceeding 15 m. Alternatively, the three single-core cables of different phases may be installed in a trefoil formation. The above precautions are, however, not necessary when the length of the run is less than 30 m.
(7) In circuits with several single-core cables in parallel for each phase, all cables are to follow the same route and have the same cross-sectional area.
In addition, cables belonging to the same phase are, as far as practicable, to be alternated with those of other phases so that an unequal division of current is avoided. For instance, in the case of six cables for each phase, the correct dispositions are as shown in Table 2.12.19.1.

Disposition of Cables **Table 2.12.19.1**

Cables in parallel for each phase	1-layer disposition	2-layer disposition
2	ABC CBA	ABC CBA
3		ABCA BCABC
4		ABCABC CBACBA
5		ABCABCA BCABCABC
6		ABCABCABC CBACBACBA

2.12.20 Installation of cables with respect to prevention of electromagnetic interference

2.12.20.1 In order to minimize the effects of unwanted electromagnetic interference, cables are to be installed in accordance with the relevant standards① accepted by ISC.

2.12.21 Earthing of metal protective coverings of cables

2.12.21.1 The earthing of metal protective coverings (braid or armour) of cables is to be in accordance with the relevant requirements of Section 3, Chapter 1 of this PART.

2.12.22 Cable ends

2.12.22.1 The ends of all conductors of a cross-sectional area greater than 4 mm^2 are to be fitted with soldered sockets, compression type sockets or mechanical clamps. Corrosive fluxes are not to be used.

2.12.22.2 The temperature of cable sockets and terminals is, in general, not to exceed the maximum operating temperature of insulated cables.

2.12.22.3 The fixing of conductors in terminals at joints and at tappings is to be capable of withstanding the thermal and dynamic effects of short-circuit currents.

2.12.23 Joints and tappings

2.12.23.1 Cable runs are normally not to include joints. If a joint is necessary in the case of repair or sectional construction of the ship, the joint is to be such that the electrical continuity, insulation, mechanical strength and protection, earthing and fire-resisting or flame-retardant characteristics are not inferior to those required for the cables.

2.12.23.2 Tappings are to be made in suitable boxes of such a design that the conductors remain suitably insulated, protected from atmospheric action and fitted with terminals or bus-bars of dimensions appropriate to the current rating.

2.12.23.3 Joints and tappings are to be clearly marked.

2.12.24 Connection boxes

2.12.24.1 Connection boxes are to be made of flame-retardant material. Mountings of live parts are to be robust, durable, flame-retardant and moisture-resistant, having permanently insulation resistance with high dielectric strength.

2.12.24.2 Live parts within the box are to be suitably spaced or provided with shielding by flame-retardant insulating material so that a short-circuit will not occur between conductors of different polarity or between conductors and earthed metal.

2.12.24.3 Each connection box is to be provided with a nameplate indicating its purpose or a durable no. mark corresponding to the wiring diagram. Where the connection boxes are installed in a concealed manner, the panelling in way of the boxes is to be arranged for easy removal.

2.12.25 Cable trays/protective casings made of plastic materials

2.12.25.1 Cable trays/protective casings② made of plastic③ materials are to be type tested in accordance with Appendix 2 of this PART − "Type Approval Procedure for Cable Trays/Protective Casings Made of Plastic Materials".

---

① Refer to IEC Publication 60533: Electrical and Electronic Installations in Ships – Electromagnetic Compatibility, or the relevant requirements in relevant standards.

② "Protective casing" means a closed cover in the form of a pipe or other closed ducts of non-circular shape.

③ "Plastic" means both thermoplastic and thermosetting plastic materials with or without reinforcement, such as PVC and fibre reinforced plastics - FRP.

2.12.25.2 Cable trays/protective casings made of plastic materials are to be supplemented by metallic fixing and straps such that in the event of a fire they, and the cables affixed, are prevented from falling and causing an injury to personnel and/or an obstruction to any escape route. When plastic cable trays/protective casings are used on open deck, they are additionally to be protected against UV light.
2.12.25.3 The load on the cable trays/protective casings is to be within the Safe Working Load (SWL). The support spacing is not to be greater than the manufacturer's recommendation nor in excess of spacing at the SWL test. In general the spacing is not to exceed 2 m. The selection and spacing of cable tray/protective casing supports are to take the following into account:
(1) cable trays/protective casings' dimensions;
(2) mechanical and physical properties of their material;
(3) mass of cable trays/protective casings;
(4) loads due to weight of cables, external forces, thrust forces and vibrations;
(5) maximum accelerations to which the system may be subjected;
(6) combination of loads.
2.12.25.4 The sum of the cables' total cross-sectional area, based on the cables' external diameter, is not to exceed 40% of the protective casing's internal cross-sectional area. This does not apply to a single cable in a protective casing.

Section 13 LIGHTNING PROTECTION

2.13.1 Protection against primary structural damage

2.13.1.1 A protective system need not be fitted to a ship of metallic construction where a low resistance path to earth will be inherently provided by masts, structural members and the hull.
2.13.1.2 A protective system is to be fitted to any ship having a substantial number of non-metallic structural members.
2.13.1.3 The protective system is to be comprised of air terminal, down conductor and earth termination.
2.13.1.4 Metallic masts and metallic structural members may form part or all of any protective system.
2.13.1.5 The metal rigging, such as stays, shrouds, etc., are to be bonded to the protective system.
2.13.1.6 Joints in down conductors are to be accessible and be located or protected so as to minimize accidental damage. They are to be made by means of copper rivets or clamps. Clamps may be of copper or of copper alloy and are to preferably be of the serrated contact type and effectively locked. No connection is to be dependent on a soldered joint.
2.13.1.7 The resistance between air terminals and earth terminations is not to exceed 0.02 Ω.
2.13.1.8 Suitable means are to be provided to enable ships when in dry dock, or on a slipway, to have their protective systems or metal hull connected to an efficient earth on shore. Connecting cables to the shore earth is to be external to the earth throughout their length.
2.13.1.9 Air terminals of the protective system are to comply with the following requirements:
(1) An air terminal is to be fitted to each non-metallic mast.
(2) Air terminals are to be made of copper or copper alloy conducting bar of not less than 12 mm diameter, and are to project at least 300 mm beyond the top of the mast. Other materials may be used, for example stainless steel or aluminium alloys, or steel bar effectively protected against corrosion, subject to the requirement of 2.13.1.7. The material is to be resistant to sea water.
(3) Vent outlets for flammable gases located at or near the top of masts on tankers are to be protected by air terminals which extend at least 2 m above the vent outlet. A steel mast may serve as the air terminal if it extends 2 m above the outlet.
2.13.1.10 Down conductors of the protective system are to comply with the following requirements:
(1) Down conductors are to be made of copper, or copper alloy tape or cable. Cable is preferred as both the insulation and the circuit shape inhibit surface discharge. Other materials may be used, for example stainless steel or aluminium alloys, subject to the requirement of 2.13.1.7. The material is to be resistant to sea water.
(2) Down conductors of copper are to have a minimum cross-section of 70 mm^2, be firmly secured to the structure and be run as straight as possible between the air terminal and the earth termination. Bends, where necessary, are to have a minimum radius of at least 10 times the equivalent diameter of the conductor.
2.13.1.11 The ends of down conductors are to be reliably bonded to the earth terminations of the metallic construction of the ship nearby. Where necessary, measures are to be taken for preventing electrochemical corrosion.

2.13.2 Protection against secondary damage

2.13.2.1 On all ships, equipment is to be so installed as to minimize the effect of secondary damage caused by lightning to the electrical system.
2.13.2.2 Metallic enclosures are to be reliably earthed. Particular attention is to be paid to navigation lights and other equipment at the top of masts and on other elevated structures.
2.13.2.3 Cable screens or armour, though normally earthed for signal interference suppression, are not to provide the sole lightning path to earth for equipment. Separate earthing, as required in 2.13.2.2, is to be provided.
2.13.2.4 The formation of cable loops, or metallic loops such as pipework, in proximity to down conductors of the protective system required in 2.13.1.2 is to be avoided. Cables in close proximity to down conductors are to be installed in metal pipes.
2.13.2.5 Cables along decks are to be installed close to the deck and advantage is to be taken of the screening effect of earthed metallic structures near to or above the cable runs, for examples handrails, pipes, etc.
2.13.2.6 Means are to be provided for the discharging to earth of any lightning energy that may be induced in for example radio and navigational equipment antennas. Consideration is to be given to installing devices such as spark gaps or surge diverters to provide protection from voltage transients.

Section 14 SPECIAL REQUIREMENTS FOR HIGH VOLTAGE ELECTRICAL INSTALLATIONS

2.14.1 General requirements

2.14.1.1 This Section applies to AC three-phase systems with nominal voltage (voltage between phases) exceeding 1 kV. If not otherwise stated herein, construction and installation applicable to low voltage equipment generally apply to high voltage equipment.
2.14.1.2 The nominal system voltage is not to exceed 15 kV. Where necessary for special application, higher voltages may be accepted by ISC.
2.14.1.3 Equipment with voltage above about 1 kV is not to be installed in the same enclosure as low voltage equipment, unless segregation or other suitable measures are taken to ensure that access to low voltage equipment is obtained without danger.

2.14.2 System design

2.14.2.1 The distribution of high-voltage electrical installations is to comply with the following:
(1) It is to be possible to split the main switchboard into at least two independent sections, by means of at least one circuit breaker or other suitable disconnecting devices, each supplied by at least one generator. If two separate switchboards are provided and interconnected with cables, a circuit breaker is to be provided at each end of the cable.
Services which are duplicated are to be divided between the sections.
(2) For earthed neutral systems in case of earth fault, the current is not to be greater than full load current of the largest generator on the switchboard or relevant switchboard section and not less than three times the minimum current required to operate any device against earth fault.
It is to be assured that at least one source neutral to ground connection is available whenever the system is in the energized mode. Electrical equipment in directly earthed neutral or other neutral earthed systems is to withstand the current due to a single phase fault against earth for the time necessary to trip the protection device.
(3) Means of disconnection are to be fitted in the neutral earthing connection of each generator so that the generator may be disconnected for maintenance and for insulation resistance measurement.
(4) All earthing impedances are to be connected to the hull. The connection to the hull is to be so arranged that any circulating currents in the earth connections do not interfere with radio, radar, communication and control equipment circuits.
(5) In the systems with neutral earthed, connection of the neutral to the hull is to be provided for each separate section of the main switchboard.
2.14.2.2 The degrees of protection provided by enclosures for the high-voltage electrical equipment is to be appropriate to the location of installation, as a minimum in compliance with the requirements of Table 1.3.2.2 of this PART and in addition the following:
(1) The degree of protection by enclosures for rotating electrical machines is to be at least IP23. The degree of protection of terminals is to be at least IP44. For motors installed in spaces accessible to unqualified personnel, a degree of protection against approaching or contact with live or moving parts of at least IP4X is required.

(2) The degree of protection by enclosures for transformers is to be at least IP23. For transformers installed in spaces accessible to unqualified personnel, a degree of protection of at least IP4X is required.
For transformers not contained in enclosures, 2.14.7.1 of this Section is to be complied with.
(3) The degree of protection of metal enclosed switchgear, control gear assemblies and static convertors is to be at least IP32. For switchgear, control gear assemblies and static converters installed in spaces accessible to unqualified personnel, a degree of protection of at least IP4X is required.
2.14.2.3 The air clearances and creepage distances are to comply with the following:
(1) In general, for non-type-tested equipment phase-to-phase air clearances and phase-to-earth air clearances between non-insulated parts are not to be less than those specified in Table 2.14.2.3.
Where intermediate values of nominal voltages are accepted, the next higher air clearance is to be observed. In the case of smaller clearances, appropriate voltage impulse test is to be applied.

Minimum Air Clearances **Table 2.14.2.3**

Nominal voltage (kV)	Minimum air clearance (mm)
3 (3.3)	55
6 (6.6)	90
10 (11)	120
15	160

(2) Creepage distances between live parts and between live parts and earthed metal parts for standard components are to be in accordance with IEC publication 60092-503 for the nominal voltage of the system, the nature of the insulation material and the transient overvoltage developed by switch and fault conditions.
2.14.2.4 For protection of the high-voltage electrical system, the following special requirements are to be complied with:
(1) Protective devices are to be provided against phase-to-phase faults in the cables connecting the generators to the main switchboard and against interwinding faults within the generators. The protective devices are to trip the generator circuit breaker and automatically de-excite the generator.
In distribution systems with a neutral earthed, phase to earth faults are also to be treated as above.
(2) Any earth fault in the system is to be indicated by means of a visual and audible alarm. In low impedance or direct earthed systems (a system is defined effectively earthed when the earthing factor① is lower than 0.8), provision is to be made to automatically disconnect the faulty circuits. In high impedance earthed systems (a system is defined non-effectively earthed when the earthing factor is higher than 0.8), where outgoing feeders will not be isolated in case of an earth fault, the insulation of the equipment is to be designed for the phase to phase voltage.
(3) Power transformers are to be provided with overload and short circuit protection. When transformers are connected in parallel, tripping of the protective devices at the primary side has to automatically trip the switch connected at the secondary side.
(4) Voltage transformers are to be provided with overload and short circuit protection on the secondary side.
(5) Fuses are not to be used for overload protection.
(6) Lower voltage systems supplied through transformers from high voltage systems are to be protected against overvoltages. This may be achieved by:
① direct earthing of the lower voltage system;
② appropriate neutral voltage limiters;
③ earthed screen between the primary and secondary windings of transformers.

2.14.3 Rotating machinery

2.14.3.1 Generator stator windings are to have all phase ends brought out for the installation of the differential protection.
2.14.3.2 Rotating machinery is to be provided with temperature detectors in their stator windings to actuate a visual and audible alarm in a normally attended position whenever the temperature exceeds the permissible limit.
If embedded temperature detectors are used, means are to be provided to protect the circuit against overvoltage.
2.14.3.3 In addition to the tests normally required for rotating machinery, a high frequency high voltage

① Earthing factor is defined as the ratio between the phase to earth voltage of the health phase and the phase to phase voltage. This factor may vary between $1/\sqrt{3}$ and 1.

test in accordance with acceptable standard(s)[①] is to be carried out on the individual coils in order to demonstrate a satisfactory withstand level of the inter-turn insulation to steep fronted switching surges.

2.14.4 Power transformers

2.14.4.1 Dry type transformers are to comply with acceptable standard(s)[②], and liquid cooled transformers are also to comply with acceptable standard(s)[③].

2.14.4.2 Oil immersed transformers are to be provided with the following alarms and protections:

(1) liquid level (Low) – alarm;

(2) liquid temperature (High) – alarm;

(3) liquid level (Low) – trip or load reduction;

(4) liquid temperature (High) – trip or load reduction;

(5) gas pressure relay (High) – trip.

2.14.5 Cables

2.14.5.1 Cables are to be constructed in accordance with acceptable standards[④].

2.14.6 Switchgear and control gear assemblies

2.14.6.1 Switchgear and control gear assemblies are to be constructed according to acceptable standards[⑤].

2.14.6.2 Switchgear and control gear assemblies are to be constructed in accordance with the following requirements:

(1) Switchgear is to be of metal-enclosed type or of the insulation-enclosed type in accordance with acceptable standard(s)[⑥].

(2) Withdrawable circuit breakers and switches are to be provided with mechanical locking facilities in both service and disconnected positions. For maintenance purposes, key locking of withdrawable circuit breakers and switches and fixed disconnectors is to be possible.

Withdrawable circuit breakers are to be located in the service position so that there is no relative motion between fixed and moving portions.

(3) The fixed contacts of withdrawable circuit breakers and switches are to be so arranged that in the withdrawable position the live contacts are automatically covered. Shutters are to be clearly marked for incoming and outgoing circuits. This may be achieved with the use of labels or colours.

(4) For maintenance purposes an adequate number of earthing and short-circuiting devices is to be provided to enable circuits to be worked upon with safety.

(5) Switchgear and controlgear assemblies are to be internal arc classified (IAC). Where switchgear and controlgear assemblies are accessible by authorized personnel only, Accessibility Type A is sufficient (refer to IEC 62271-200; Annex AA; AA 2.2). Accessibility Type B is required if accessible by non-authorized personnel. Installation and location of the switchgear and controlgear assemblies are to correspond with their internal arc classification and classified sides (F, L and R).

2.14.6.3 Requirements for auxiliary systems

(1) If electrical energy and/or physical energy is required for the operation of circuit breakers and switches, a store supply of such energy is to be provided for at least two consecutive operations of all the components. However, the tripping due to overload or short-circuit, and under-voltage is to be independent of any stored electrical energy sources. This does not preclude shunt tripping provided that alarms are activated upon lack of continuity in the release circuits and power supply failures.

(2) When external source of supply is necessary for auxiliary circuits, at least two external sources of supply are to be provided and so arranged that a failure or loss of one source will not cause the loss of more

---

① Refer to IEC Publication 60034-15 Rotating electrical machines – Part 15: Impulse voltage withstand levels of rotating AC machines with form-wound stator coils, or other equivalent standards.

② Refer to IEC Publication 60076-11 Dry-type power transformers, or other equivalent standards.

③ Refer to the applicable Parts of the IEC 60076 Series, or other equivalent standards.

④ Refer to IEC Publication 60092-353 Electrical installations in ships – Part 353: Power cables for rated voltages 1 kV and 3 kV and IEC Publication 60092-354 Electrical installations in ships – Part 354: Single- and three-core power cables with extruded solid insulation for rated voltages 6 kV (Um = 7.2 kV) up to 30 kV (Um = 36 kV).

⑤ Refer to IEC Publication 62271-200: AC metal-enclosed switchgear and control gear for rated voltages above 1 kV and up to and including 52 kV, or other equivalent standards.

⑥ Refer to IEC Publication 62271-200: AC metal-enclosed switchgear and control gear for rated voltages above 1 kV and up to and including 52 kV, and compliance with IEC Publication 62271-201: AC insulation-enclosed switchgear and control gear for rated voltages above 1 kV and up to and including 52 kV.

than one generator set and/or set of essential services. Where necessary, one source of supply is to be from the emergency source of electrical power for the start-up from dead ship condition.

2.14.6.4 A power-frequency voltage test is to be carried out on any switchgear and control gear assemblies. The test procedure and voltages are to be according to acceptable standard(s)[①].

2.14.7 Installation

2.14.7.1 Where equipment is not contained in an enclosure but a room forms the enclosure of the equipment, the access doors are to be so interlocked that they cannot be opened until the supply is isolated and the equipment earthed down.

At the entrance of the spaces where high-voltage electrical equipment is installed, a suitable marking is to be placed which indicates danger of high-voltage. As regards the high-voltage electrical equipment installed outside a.m. spaces, the similar marking is to be provided.

An adequate, unobstructed working space is to be left in the vicinity of high voltage equipment for preventing potential severe injuries to personnel performing maintenance activities. In addition, the clearance between the switchboard and the ceiling/deckhead above is to meet the requirements of the internal arc classification[②].

2.14.7.2 Run of high-voltage cables is to comply with the following:

(1) In accommodation spaces, high voltage cables are to be run in enclosed cable transit systems.

(2) High voltage cables are to be segregated from cables operating at different voltage ratings each other; in particular, they are not to be run in the same cable bunch, nor in the same duct or pipe, or, in the same box. Where high voltage cables of different voltage ratings are installed on the same cable tray, the air clearance between cables is not to be less than the minimum air clearance for the higher voltage side in 2.14.2.3(1) of this Section. However, high voltage cables are not to be installed on the same cable tray for the cables operating at the nominal system voltage of 1 kV and less.

(3) High-voltage cables, in general, are to be installed on carrier plating when they are provided with a continuous metallic sheath or armour which is effectively bonded to earth; otherwise they are to be installed for their entire length in metallic casings effectively bonded to earth.

(4) Terminations in all conductors of high voltage cables are to be, as far as practicable, effectively covered with suitable insulating material. In terminal boxes, if conductors are not insulated, phases are to be separated from earth and from each other by substantial barriers of suitable insulating materials. High voltage cables of the radial field type, i.e. having a conductive layer to control the electric field within the insulation, are to have terminations which provide electric stress control.

Terminations are to be of a type compatible with the insulation and jacket material of the cable and are to be provided with means to ground all metallic shielding components (i.e. tapes, wires etc.).

(5) High-voltage cables are to be readily identifiable by suitable marking.

(6) Before a new high voltage cable installation, or an addition to an existing installation, is put into service, a voltage withstand test is to be satisfactorily carried out on each completed cable and its accessories. After completion of the test the conductors are to be connected to earth for a sufficient period in order to remove any trapped electric charge. An insulation resistance test is then repeated. The voltage withstand test is to be carried out in accordance with the following methods:

① For cables with rated voltage above 1.8/3 kV (U_m[③]=3.6 kV) an a.c. voltage withstand test may be carried out upon advice from high voltage cable manufacturer. One of the following test methods may be used: test for 5 min with the phase-to-phase voltage of the system applied between the conductor and the metallic screen/sheath, or test for 24 h with the normal operating voltage of the system; alternatively, a d.c. test voltage equal to 4 U_0 may be applied for 15 min.

② For cables with rated voltage up to 1.8/3 kV (U_m=3.6 kV) a d.c. voltage equal to 4 U_0 is to be applied for 15 min.

---

① Refer to IEC Publication 62271-200: AC metal-enclosed switchgear and control gear for rated voltages above 1 kV and up to and including 52 kV – Part 7: Routine test, or other equivalent standards.

② Refer to 6.2.5 of IEC Publication 62271-200: AC metal-enclosed switchgear and control gear for rated voltages above 1 kV and up to and including 52 kV.

③ *U*m is the maximum value of the "highest system voltage" for which the equipment may be used. Highest system voltage is the highest value of voltage which occurs under normal operating conditions at any time and at any point on the system. It excludes voltage transients, such as those due to system switching, and temporary voltage variations.

Section 15 ADDITIONAL REQUIREMENTS FOR ELECTRICAL PROPULSION MACHINERY

Electrical propulsion machinery is to comply with the applicable requirements of this PART and the requirements of Chapter 15, PART EIGHT of the Rules.

Section 16 ADDITIONAL REQUIREMENTS FOR OIL TANKERS

2.16.1 General requirements

2.16.1.1 Electrical installations on tankers carrying crude oil and oil products are to comply with the provisions of this Section and other provisions of this PART as appropriate.

2.16.1.2 The classification of typical hazardous areas of oil tankers is carried out in accordance with zone 0, zone 1 and zone 2 based on the provisions of IEC60092-502 in this Section. For areas or spaces not mentioned in this Section, the classification of hazardous areas may be carried out in accordance with the principles given in IEC60079-10-1.

2.16.1.3 Electrical equipment and cables are, in principle, not to be installed in any hazardous areas. If it is impracticable to avoid doing so, the relevant provisions of this Section are to be complied with.

2.16.2 Distribution systems

2.16.2.1 The following distribution systems may be used:

(1) DC, two-wire, insulated;

(2) AC, single-phase, two-wire, insulated;

(3) AC, three-phase, three-wire, insulated.

2.16.2.2 No direct electrical connection is allowed between power networks operating at different voltages.

2.16.2.3 All circuits of generation, supply and distribution systems are not to be earthed, and hull return system is not permitted with the following exceptions:

(1) intrinsically safe circuits;

(2) power supplied control circuits and instrumentation circuits where technical or safety reasons preclude the use of a system with no connection to earth, provided the current in the hull is limited to not more than 5 A in both normal and fault conditions;

(3) limited and locally earthed systems, provided that any possible resulting current does not flow directly through any of the hazardous spaces;

(4) AC distribution systems with 1,000 V (root mean square) and over between phases, provided that any possible resulting current does not flow directly through any of the hazardous spaces.

2.16.3 Cables and their installation

2.16.3.1 All cables, other than those of intrinsically safe circuits, installed in zone 0 and zone 1, are to be provided with an impervious sheath in combination with braiding or other metallic covering.

2.16.3.2 Cables of intrinsically safe circuits are to have a metallic shielding with at least an impervious sheath.

2.16.3.3 Where cables are subject to lengthy immersion in the cargo, the construction of the cables is to be such as to withstand the substances to which they can be exposed, or the cables are to be enclosed in casings (such as metallic pipes) capable of withstanding such substances.

2.16.3.4 Where corrosion may be expected, an impervious sheath is to be applied over the metal braid or armour of the cable.

2.16.3.5 Where cables pass through gastight bulkheads or decks separating hazardous areas from non-hazardous areas, arrangements are to be such that the gastight integrity of the bulkhead or deck is not impaired.

2.16.3.6 Cables installed on deck or on fore and aft gangways are to be protected against mechanical damage. Cables are to be so installed as to avoid strain or chafing and due allowance is to be made for expansion or working of the structure. Where ring-type expansion bends are fitted, they are to be accessible for maintenance.

2.16.3.7 Cables installed in pump rooms are to be suitably protected against mechanical damage.

2.16.3.8 Flexible cables or wires for portable electrical appliances are not to pass through hazardous areas or spaces, with the exception of flexible cables or wires of intrinsically safe type.

2.16.4 Electrical equipment in hazardous areas

2.16.4.1 For electrical equipment installed in hazardous areas, the appropriate certified explosion-proof equipment is to be selected in accordance with the category of hazardous areas, and the explosion group and temperature class are not to be lower than II A T3.

2.16.4.2 The following equipment is allowed to be installed in zone 0:

(1) certified intrinsically-safe apparatus of category "ia";

(2) simple electrical apparatus and components (for example thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically safe circuits of category "ia", not capable of storing or generating electrical power or energy in excess of the limits given in IEC 60079-14;

(3) submersible pumps, having at least two independent methods of shutting down automatically in the event of low liquid level.

2.16.4.3 The following equipment is allowed to be installed in zone 1:

(1) electrical equipment specified in 2.16.4.2 of this Section;

(2) certified intrinsically-safe apparatus of category "ib";

(3) simple electrical apparatus and components (for example thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically safe circuits of category "ib", not capable of storing or generating electrical power or energy in excess of the limits given in IEC 60079-14;

(4) certified flameproof (type "d");

(5) certified pressurized (type "p");

(6) certified increased safety (type "e");

(7) certified encapsulated (type "m");

(8) certified sand filled (type "q");

(9) certified specially (type "s")[①];

(10) anodes or electrodes of an impressed current cathodic protection system, or transducers such as those for depth-sounding or log systems, provided that such fittings are housed within a gastight enclosure, and are not located adjacent to a cargo tank bulkhead;

(11) through runs of cable.

2.16.4.4 The following equipment is allowed to be installed in zone 2:

(1) electrical equipment specified in 2.16.4.3 of this Section;

(2) non-sparking electrical equipment "n";

(3) the type which ensures the absence of sparks and arcs and of "hot spots" during its normal operation.

2.16.4.5 Transmitting aerials and any associated riggings are to be sited well clear of gas and vapour outlets.

2.16.4.6 For the electrical equipment permitted in hazardous areas or spaces, all switches and protective devices are to be capable of interrupting all poles or phases and are to be located in a non- hazardous area or space. Such equipment, switches and protective devices are to be clearly and durably labelled for identification purposes.

2.16.5 Earth connection and static electricity protection

2.16.5.1 The metal casings of all electrical equipment in any hazardous areas or spaces, regardless of the working voltage, are to be reliably earthed.

2.16.5.2 Cargo tanks, process plants and piping systems are to be earthed in accordance with 1.3.4.12 of this PART for the control of static electricity.

2.16.5.3 All rigging is to be effectively bonded to ship's hull.

2.16.6 Classification of hazardous areas of oil tankers carrying cargo oils having a flash point (closed cup) not exceeding 60℃

2.16.6.1 Zone 0 is to include the following areas or spaces:

(1) cargo tanks, slop tanks, any pipework of pressure-relief or other venting systems for cargo and slop tanks;

(2) interior spaces containing the pipes and equipment containing cargo oil.

2.16.6.2 Zone 1 is to include the following areas or spaces:

(1) cofferdams and ballast tanks adjoining cargo tanks;

(2) cargo pump rooms and the mechanical ventilation is to comply with the following requirements:

① audible and visual alarms are to be given at a manned location in case of failure of the mechanical

---

① Where explosion-proof types (flameproof, increased safety, intrinsically-safe, pressurized, oil filled, sand filled, encapsulated and non-sparking) not included in the special standards are used for electrical equipment, they may be treated as electrical equipment certified specially (type "s").

ventilation in the cargo pump room;

② actions are to be taken to restore ventilation immediately after failure of the mechanical ventilation;

③ where the mechanical ventilation can not be restored for an extended period, the remaining electrical equipment other than those mentioned below is to be capable of being disconnected outside of hazardous areas and provided with means against unauthorized re-connections:
(a) intrinsically safe equipment;
(b) flameproof lighting;
(c) general emergency alarm sounder of flameproof type, without internal sparking contacts;

④ where the mechanical ventilation has been stopped for an extended period or it is initially used, the cargo pump room is to be purged for at least five air changes before connecting the electrical equipment (except the intrinsically safe equipment, flameproof lighting and general emergency alarm sounder of flameproof type);

(3) enclosed or semi-enclosed spaces immediately above cargo tanks (e.g. 'tween-deck spaces) or having bulkheads above and in line with cargo tank bulkheads;

(4) spaces other than cofferdams adjoining to and below the top of a cargo oil tank (e.g. trunks, passageways and general cargo holds), and double bottom and pipe tunnels below cargo tanks;

(5) areas on open deck, or semi-enclosed spaces on open deck, within 3 m of any cargo tank outlet, gas or vapour outlet[①], cargo manifold valve, cargo valve, cargo pipe flange, cargo pump-room ventilation outlets and cargo tank pressure/vacuum relief valve provided to permit the flow of small volumes of gas or vapour mixtures caused by thermal variation;

(6) areas on open deck, or semi-enclosed spaces on open deck above and in the vicinity of any cargo gas outlet intended for the passage of large volumes of gas or vapour mixture during cargo loading and ballasting or during discharging, within a vertical cylinder of unlimited height and 6 m radius centred upon the centre of the outlet, and within a hemisphere of 6 m radius below the outlet;

(7) areas on open deck, or semi-enclosed spaces on open deck, within 1.5 m of cargo pump room entrances, cargo pump room ventilation inlet, openings into cofferdams or other zone 1 spaces;

(8) areas on open deck over all cargo tanks (including all ballast tanks within the cargo tank area) where structures are restricting the natural ventilation and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2.4 m above the deck;

(9) areas on open deck within spillage coamings surrounding cargo manifold valves and 3 m beyond these, up to a height of 2.4 m above the deck;

(10) compartments for cargo hoses;

(11) enclosed or semi-enclosed spaces in which pipes containing cargoes are located;

(12) fore peak tank and vent pipe openings as defined in 3.4.14.1, Chapter 3, PART SIX of the Rules.

2.16.6.3 Zone 2 is to include the following areas or spaces:

(1) areas of 1.5 m surrounding the open spaces or semi-enclosed spaces in zone 1 as specified in 2.16.6.2, if not otherwise specified in this standard;

(2) spaces 4 m beyond the area defined in 2.16.6.2(6);

(3) areas within 2 m beyond areas on open deck, or semi-enclosed spaces on open deck, within 3 m of any cargo tank outlet, cargo tank pressure/vacuum relief valve provided to permit the flow of small volumes of gas or vapour mixtures caused by thermal variation;

(4) the spaces forming an air-lock leading to zone 1;

(5) areas on open deck extending to the coamings fitted to keep any spills on deck and away from the accommodation and service areas and 3 m beyond these up to a height of 2.4 m above the deck;

(6) areas on open deck over all cargo tanks (including all ballast tanks within the cargo tank area) where unrestricted natural ventilation is guaranteed and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2.4 m above the deck surrounding open or semi-enclosed spaces of zone 1;

(7) spaces forward of the open deck areas to which reference is made in 2.16.6.2(8) and 2.16.6.3(6) of this Section, below the level of the main deck, and having an opening on to the main deck or at a level less than 0.5 m above the main deck, unless:

① the entrances to such spaces do not face the cargo tank area and, together with all other openings to the spaces, including ventilating system inlets and exhausts, are situated at least 5 m from the foremost cargo tank and at least 10 m measured horizontally from any cargo tank outlet or gas or vapour outlet; and

② the spaces are mechanically ventilated.

---

① Such areas are sight ports, tank cleaning openings, ullage openings, sounding pipes, cargo vapour outlets.

2.16.6.4 The hazards in some hazardous areas or spaces, e.g. those having direct openings into hazardous areas or spaces, may be reduced or these zones or spaces may be regarded as non-hazardous areas or spaces, provided that the arrangements of ventilation, pressurization, doors at openings, and other safety precautions are in compliance with relevant acceptable standards①.

2.16.7 Classification of hazardous areas of oil tankers carrying cargo oils having a flash point (closed cup) exceeding 60℃ and not heated or heated to a temperature more than 15℃ below their flash point

2.16.7.1 The interiors of cargo tanks, slop tanks, any pipework of pressure/vacuum relief valve or other venting systems for cargo and slop tanks, pipes and equipment containing the cargo or handling flammable gas or vapour belong to zone 2.

2.16.8 Classification of hazardous areas of oil tankers carrying cargo oils having a flash point (closed cup) exceeding 60℃ and heated to a temperature above their flash point or heated to a temperature within 15℃ of their flash point

2.16.8.1 Such tankers are to comply with the requirements for oil tankers carrying cargo oils having a flash point (closed cup) not exceeding 60℃, as specified in 2.16.6 of this Section.

Section 17 ADDITIONAL REQUIREMENTS FOR SHIPS CARRYING VEHICLES WITH FUEL IN THEIR TANKS FOR THEIR OWN PROPULSION

2.17.1 General requirements

2.17.1.1 This Section applies to the electrical installations of ships with spaces for carrying vehicles with fuel in their tanks for their own propulsion.

2.17.1.2 The certified explosion-proof equipment required by this Section is to comply with the provisions of 1.3.3 of this PART, and the explosion group and temperature class are not to be lower than II A, T3.

2.17.2 Carriage of vehicles in special category spaces above the bulkhead deck of passenger ships and in closed ro-ro spaces and closed vehicle spaces (with not less than 10 air changes per hour) of passenger ships and cargo ships

2.17.2.1 The electrical equipment fitted within a height of 450 mm above the vehicle deck or any platform on which vehicles are carried and within the exhaust ventilation trunking for the spaces is to be of certified safe type.

2.17.2.2 In spaces other than those specified in 2.17.2.1, where electrical equipment other than that of certified safe type is fitted, the enclosure of which is to be of at least IP55 type.

2.17.3 Carriage of vehicles in special category spaces below the bulkhead deck of passenger ships and in closed ro-ro spaces and closed vehicle spaces (with less than 10 air changes per hour) of passenger ships and cargo ships

2.17.3.1 The electrical equipment fitted within such spaces and their exhaust ventilation trunking are to be of certified safe type.

2.17.4 Carriage of vehicles in cargo spaces other than vehicle, special category or ro-ro spaces

2.17.4.1 On all ships, when vehicles with fuel in their tanks for their own propulsion are carried in cargo spaces other than vehicle, special category or ro-ro spaces, the requirements of SOLAS regulation II-2/20.2.1.2 are to be complied with.

2.17.5 Carriage of vehicles in open ro-ro spaces, open vehicle spaces and an area on weather deck of passenger ships and cargo ships

2.17.5.1 For the electrical equipment fitted in the area, the degrees of protection by enclosures are to comply with the relevant requirements of Table 1.3.2.2 of this PART.

① See IEC publication 60092-502: Electrical installations in ships –Part 502: Tankers – Special Features.

Section 18 ADDITIONAL REQUIREMENTS FOR SHIPS CARRYING DANGEROUS GOODS

2.18.1 General requirements

2.18.1.1 The electrical installations onboard ships fitted with cargo spaces intended for carrying dangerous goods specified in 2.18.1.2 are to comply with the requirements of this Section and other applicable requirements of this PART.

2.18.1.2 Dangerous goods, for which safety measures are required with respect to the electrical equipment, are grouped into the following classes in accordance with IMO International Maritime Dangerous Goods Code (IMDG Code) and International Maritime Solid Bulk Cargoes (IMSBC) Code:

(1) Dangerous goods in packaged form

Class 1 Explosives, except goods in division 1.4, compatibility group S of IMDG Code;

Class 2.1 All flammable gases, compressed, liquefied or dissolved under pressure;

Class 2.3 All toxic gases having a subsidiary risk class 2.1;

Class 3 All flammable liquids having a flashpoint below 23℃ (closed-cup test);

Class 4.3 Liquids having a flashpoint below 23℃, which in contact with water, emit flammable gases;

Class 6.1 All toxic substances having a flashpoint below 23℃ (closed-cup test);

Class 8 All corrosive liquids having a flashpoint below 23℃ (closed-cup test);

Class 9 Miscellaneous dangerous substances emitting flammable gases.

(2) Solid dangerous goods in bulk

Class 4.1 Flammable solids;

Class 4.2 Substances liable to spontaneous combustion;

Class 4.3 Substances, which in contact with water, emit flammable gases;

Class 5.1 Oxidizing substances;

Class 9 Miscellaneous dangerous substances, that is, any other substance which experience has shown, or may show, to be of such a dangerous character that the provisions of this Section apply to it;

MHB Materials which may possess chemical hazards when transported in bulk other than materials classified as dangerous goods in the IMDG Code.

2.18.1.3 Possible hazardous areas for carrying the dangerous goods specified in this Section comprise the following:

(1) Zones and spaces, in which an explosive atmosphere① is likely to occur in normal operation, are defined as hazardous areas.

(2) Zones and spaces, in which an explosive atmosphere is not likely to occur in normal operation and, if it does occur, is likely to do so only infrequently and will exist for a short period only, are defined as extended hazardous areas.

2.18.1.4 Electrical equipment is to be installed in hazardous areas only when it is essential for the safety and operation of the ship. The explosion protection of the installed and operated electrical equipment is to be suitable for the characteristics of the dangerous goods.

2.18.2 Carriage of explosives class 1 in packaged form as specified in 2.18.1.2 (1) (except goods in division 1.4, compatibility group S)

2.18.2.1 The following zones or spaces are hazardous areas:

(1) closed cargo spaces, and closed or open ro-ro cargo spaces;

(2) permanently fixed containers (e.g. magazines).

2.18.2.2 Cables required in 2.18.8.2 and the electrical equipment not inferior to that required in Table 2.18.2.2 are permitted in the hazardous areas specified in 2.18.2.1 of this Section.

Permitted Electrical Equipment **Table 2.18.2.2**

Environment	Electrical equipment			
	Type	Explosion group	Temperature class or maximum surface temperature	Degree of protection
Explosive dust	General electrical equipment		100℃	IP65
Explosive gas	Intrinsically safe Ex "i"	IIA	T5	
	Flameproof Ex "d"	IIA		

① An explosive atmosphere may exist due to gas and/or dust.

Environment	Electrical equipment			
	Type	Explosion group	Temperature class or maximum surface temperature	Degree of protection
	Increased safety Ex “e” (only for lighting)	II		
Explosive gas and dust	Intrinsically safe Ex “i”	IIA	T5	IP65
	Flameproof enclosure Ex “d”	IIA		
	Increased safety Ex “e” (only for lighting)	II		

2.18.3 Carriage of solid dangerous goods in bulk, including classes 4.1, 4.2, 5.1, 9 and MHB creating explosive dust atmosphere

2.18.3.1 The following zones or spaces are hazardous areas:

(1) closed cargo spaces;

(2) ventilation ducts (if any) for hazardous areas;

(3) enclosed or semi-enclosed spaces having a direct opening into any of the spaces listed in (1) or (2) above, without appropriate measures to prevent flammable dust from entering.

2.18.3.2 Cables required in 2.18.8.2 and the electrical equipment not inferior to that required as follows are permitted in the hazardous areas specified in 2.18.3.1 of this Section (unless otherwise specified in 2.18.5):

(1) general electrical equipment

— degree of protection IP55;

— maximum surface temperature 200℃; or

(2) certified explosion-proof electrical equipment

— degree of protection IP55;

— temperature class T3.

2.18.3.3 Where dangerous goods are to be carried which require a lower surface temperature than that given in 2.18.3.2 of this Section, the relevant requirements are to be complied with (see also 2.18.7).

2.18.3.4 Where ammonium nitrate (UN1942) and ammonium nitrate fertilizer (UN2067) of class 5.1, ammonium nitrate fertilizer (UN2071) of class 9, ammonium nitrate-based fertilizer and ammonium nitrate-based fertilizer MHB are to be carried, all electrical equipment, other than that of certified safe type, in hazardous areas are to be electrically disconnected from the power source in accordance with the requirements of 2.18.8.1.

2.18.4 Carriage of flammable liquids having a flashpoint below 23 ℃ (classes 3, 6.1 and 8), flammable gas in packaged form (class 2.1), miscellaneous dangerous substances emitting flammable gases in packaged form (class 9) and substances emitting flammable gases in contact with water (solid class 4.3 and MHB generating flammable gases in contact with water)

2.18.4.1 The following zones or spaces are hazardous areas:

(1) closed cargo spaces and closed ro-ro cargo spaces;

(2) ventilation ducts (if any) for hazardous areas;

(3) areas on weather deck, or semi-enclosed spaces on weather deck, within 1.5 m of any exhaust ventilation outlet of a hazardous area;

(4) enclosed or semi-enclosed spaces having a direct opening into any of the spaces listed in (1) and (2) above, and without appropriate measures to prevent flammable gas from entering.

2.18.4.2 The following zones or spaces are extended hazardous areas:

(1) spaces which are separated by self-closing gastight doors (watertight doors may be regarded as gastight) from the hazardous areas as mentioned in 2.18.4.1(1) and (2), and have natural ventilation;

(2) inside the air lock (if any) adjoining the hazardous areas as mentioned in 2.18.4.1;

(3) open or semi-enclosed spaces within 1.5 m of the hazardous areas as specified in 2.18.4.1(3).

2.18.4.3 Cables required in 2.18.8.2 and the electrical equipment not inferior to that required in Table 2.18.4.3 are permitted in the hazardous areas specified in 2.18.4.1 and 2.18.4.2 of this Section (unless otherwise specified in 2.18.5).

Permitted Electrical Equipment **Table 2.18.4.3**

Type of hazardous areas	Electrical equipment		
	Type	Explosion group	Temperature class or maximum surface temperature
Hazardous areas	Intrinsically safe Ex “i”	IIC	T4
	Flameproof Ex “d”	IIC	
	Pressurized enclosure Ex “p”	II	
	Encapsulated Ex “m”	II	

Type of hazardous areas	Electrical equipment		
	Type	Explosion group	Temperature class or maximum surface temperature
Extended hazardous areas	Electrical equipment permitted in the above hazardous areas	IIC or II	T4
	Non-sparking Ex "n"	II	
	Appliances which do not generate sparks or arcs during normal operation		135℃

2.18.4.4 If cargoes to be carried do not include hydrogen gases, hydrogen mixtures or bulk cargo which may produce hydrogen under certain conditions, the explosion group required above may be IIB.

2.18.5 Carriage of solid dangerous goods in bulk and MHB only

2.18.5.1 Where solid dangerous goods in bulk (solid dangerous goods capable of creating explosive gas atmosphere) and MHB are to be carried, electrical equipment of certified safe type installed in hazardous areas are to be in compliance with the minimum requirements of Table 2.18.5.1.

Characteristics of Electrical Equipment for Use in Hazardous Areas (Example)

Table 2.18.5.1

Dangerous goods	IMO class	Dominant risk①	Protection against explosive dust atmosphere	Protection against explosive gas atmosphere

Direct reduced iron (C)	MHB (SH and/or WF)	H_2	—	IIC	T2
Ferrophosphorus (including briquettes)	MHB (WF and/or WT)	H_2	—	IIC	T1
Ferrosilicon, with at least 25% but less than 30% silicon, or 90% or more silicon (including briquettes)	MHB (WF and/or WT)	H_2	—	IIC	T1
Ferrosilicon UN1408, with	4.3	H_2	—	IIC	T1

Dangerous goods	IMO class	Dominant risk①	Protection against explosive dust atmosphere	Protection against explosive gas atmosphere	
			Degree of protection	Explosion group	Temperature class
30% or more but less than 90% silicon(including briquettes)					
Iron oxide, spent or sponge iron, spent UN1376	4.2	Dust	IP55	IIA	T2
Seed cake, containing vegetable oil UN1386	4.2	Hexane	—	IIA	T3
Seed cake UN2217	4.2	Hexane	—	IIA	T3
Seed cakes and other residues of processed oily vegetables	MHB (SH)	Dust	IP55	IIA	T3
Silicomanganese (low-carbon)	MHB(WF and/or WT and/or TX)	H_2	—	IIC	T1
Solidified fuels recycled from paper and plastics	MHB (SH)	Combustible	IP55	—	T3
Sugarcane biomass pellets	MHB(CB and/or WF and/or WT and/or OH)	Combustible, dust	IP55	IIA	T3
Sulphur UN1350 (crushed lump and coarse grained)	4.1	Combustible, dust	IP55	—	T4
Zinc Ashes UN1435	4.3	H_2	—	IIC	T2
Wood torrefied	MHB(CB and/or SH and/or CR)	Combustible, dust	IP55	—	T3
Wood pellets, containing additives and/or binders	MHB(WF)	Dust	IP55	—	T3
Wood pellets, not containing any additives and/or binders	MHB(OH)	Dust	IP55	—	T3

Note: ① The term "risk" relates only to the risk of explosion due to dangerous goods and electrical appliances.

2.18.6 Pressurized protection and air locks

2.18.6.1 Spaces having openings into adjacent hazardous spaces or areas (such as the hazardous areas specified in 2.18.4.1(4) of this Section) may be regarded as non-hazardous spaces provided they are pressurized as indicated in the acceptable standards①.

2.18.6.2 Where air locks are fitted adjacent to a hazardous area specified in 2.18.4.1, the external spaces adjacent to the air locks and fitted with natural ventilation may be regarded as non-hazardous spaces.

2.18.7 Special requirements

2.18.7.1 If no details of the characteristics of the prospected cargo are available, or if a ship is intended for the carriage of all the materials defined in 2.18.1.2, the electrical equipment permitted in hazardous areas are to be in compliance with the following requirements:

— degree of protection provided by enclosure IP65;
— maximum surface temperature 85°C;
— explosion group IIC;
— temperature class T6.

2.18.8 Installation of electrical system in hazardous areas

2.18.8.1 If the electrical equipment installed is not suitable for use in areas where a risk of explosion exists, the equipment is to be capable of being disconnected and protected against unauthorized

① See IEC publication 60092-506: Special features – Ships carrying specific dangerous goods and materials hazardous only in bulk.

re-connection. Disconnection is to be made outside the hazardous areas and be effected with isolating links or lockable switches.
2.18.8.2 Cables are to be armoured or braided, or to be laid in metallic conduits.
2.18.8.3 Cable joints in cargo spaces are to be avoided where possible. Where joints are unavoidable, they are to be enclosed in explosion-proof metallic or high strength plastic junction boxes, or encapsulated crimp sleeve cable joints.
2.18.8.4 Cable penetrations of decks and bulkheads are to be sealed against the passage of inflammable gas or vapour.

2.18.9 Portable electrical appliances in hazardous areas

2.18.9.1 Portable electrical appliances, which must be used in hazardous areas for operation of the ship, are to be of a certified safe type suitable for such areas and except for intrinsically safe circuits, generally provided with their own power source.

2.18.10 Carriage of flammable liquids having a flashpoint below 23℃ in packaged form (classes 3, 6.1 and 8), aluminium smelting by-products or aluminium remelting by-products (UN 3170), aluminium smelting or remelting by-products processed (MHB), ferrosilicon (MHB) and ferrosilicon (UN 1408)

2.18.10.1 The bilge pipes with flanges, valves, pumps, etc., constitute a source of release and the enclosing spaces (e.g. pipe tunnels, bilge pump rooms, etc.) are to be classified as an extended hazardous area (comparable with Zone 2) unless these spaces are continuously mechanically ventilated with a capacity for at least six air changes per hour.
2.18.10.2 Except where the space is protected with redundant mechanical ventilation capable of starting automatically, equipment not certified for Zone 2 are to be automatically disconnected following loss of ventilation while essential systems such as bilge and ballast systems are to be certified for Zone 2.
2.18.10.3 Where redundant mechanical ventilation is employed, equipment and essential systems not certified for Zone 2 are to be interlocked so as to prevent inadvertent operation if the ventilation is not operational. Audible and visual alarms are to be provided at a manned station if failure occurs.

Section 19 DETECTION OF WATER INGRESS IN CARGO HOLDS

2.19.1 Application

2.19.1.1 This Section applies to all bulk carriers, single hold cargo ships other than bulk carriers and multiple hold cargo ships other than bulk carriers and tankers of 500 gross tonnage and upwards engaged on international voyages. Bulk carriers mentioned in this Section are bulk carriers as defined in SOLAS Chapter XII.

2.19.2 Water level detector system

2.19.2.1 Water level detectors installed in cargo holds, ballast tanks and dry spaces are to comply with the relevant requirements of acceptable standards① in addition to the provisions of this Section, and are to be subject to type approval.
2.19.2.2 All bulk carriers to which this Section is applicable are to be fitted with water level detectors and the following requirements are to be satisfied:
(1) Audible and visual alarms are to be given in each cargo hold, one when the water level above the inner bottom in any hold reaches a height of 0.5 m and another at a height not less than 15% of the depth of the cargo hold but not more than 2.0 m. On bulk carriers to which SOLAS regulation XII/9.2 applies, detectors with only the latter alarm need be installed. For cargo holds which are used for water ballast, an alarm overriding device may be installed. The audible and visual alarms are to clearly discriminate between the two different water levels detected in each hold.
(2) In any ballast tank forward of the collision bulkhead required by SOLAS regulation II-1/12, an audible and visual alarm is to be given when the liquid in the tank reaches a level not exceeding 10% of the tank capacity. An alarm overriding device may be installed to be activated when the tank is in use.
(3) In any dry or void space other than a chain cable locker, any part of which extends forward of the foremost cargo hold, an audible and visual alarm is to be given at a water level of 0.1 m above the deck. Such alarms need not be provided in enclosed spaces the volume of which does not exceed 0.1% of the

① See resolution MSC.188(79)/Rev.2 adopted by IMO − Performance standards for water level detectors on ships subject to SOLAS regulations II-1/25, II-1/25-1 and XII/12.

ship's maximum displacement volume.

2.19.2.3 Single hold cargo ships having a length of less than 80 m and a single cargo hold below the freeboard deck or cargo holds below the freeboard deck which are not separated by at least one bulkhead made watertight up to that deck are to be fitted in such space or spaces with water level detectors, which are to give an audible and visual alarm at the navigation bridge when the water level above the inner bottom in the cargo hold reaches a height of not less than 0.3 m, and another when such level reaches not more than 15% of the mean depth of the cargo hold. The audible and visual alarms are to clearly discriminate between the two different water levels detected in each hold. The water level detectors required by this paragraph need not be fitted in ships having watertight side compartments each side of the cargo hold length extending vertically at least from inner bottom to freeboard deck.

2.19.2.4 Multiple hold cargo ships other than bulk carriers and tankers are to be fitted with water level detectors in each cargo hold intended for dry cargoes. Water level detectors are not required for cargo holds located entirely above the freeboard deck. The following requirements are to be satisfied:

(1) Giving audible and visual alarms at the navigation bridge, one when the water level above the bottom of the cargo hold reaches a height of not less than 0.3 m, and another at a height not less than 15% of the depth of the cargo hold but not more than 2 m. For cargo holds which are occasionally used for water ballast, an alarm overriding device may be installed. The visual alarms are to clearly discriminate between the two different water levels detected in each hold.

(2) As an alternative to the water level detector at a height of not less than 0.3 m as per (1) of this paragraph, a bilge level sensor serving the bilge pumping arrangements required by SOLAS regulation II-1/35-1 and installed in the cargo hold bilge wells or other suitable location is considered acceptable, subject to:

① the fitting of the bilge level sensor at a height of not less than 0.3 m at the aft end of the cargo hold;

② the bilge level sensor giving audible and visual alarm at the navigation bridge which is clearly distinctive from the alarm given by the other water level detector fitted in the cargo hold.

2.19.2.5 The audible and visual alarms specified in 2.19.2.2 to 2.19.2.4 are to be located on the navigation bridge.

2.19.2.6 Detection equipment is to be suitably corrosion resistant for all intended cargoes. Detection equipment includes the sensor and any filter and protection arrangements for the detector installed in cargo holds and other spaces.

Equipment which is to be used in refrigerated cargo spaces is to satisfy the requirements of a suitable industry standard covering the relevant service temperatures.

2.19.2.7 Detection equipment is to be electrical equipment of a certified safe type complying with the requirements of 1.3.3.1, Chapter 1 of this PART. The explosion groups and temperature classes are determined in accordance with carried cargoes. The part of the water level detector system which has circuitry in the cargo area is to be of an intrinsically safe type and explosion protection type as specified in acceptable standards[①]. Where a ship is designed only for the carriage of cargoes that cannot create a combustible or explosive atmosphere, then the requirement for electrical equipment of certified safe type may not be mandatory provided that this is specified in the operation manual of the water level detector system, the ship's cargo book and the certificate relating to the carriage of specially identified cargoes.

2.19.2.8 Where the characteristics of the dust and gas are unknown, the explosion group of electrical equipment used in dust and/or gas hazardous space is not to be lower than IIIC and/or IIC and the temperature class is to be T6.

2.19.2.9 The electrical power supply for the water level detector system is to comply with the following:

(1) It is to be supplied from two independent sources of electrical power:

① the main source of electrical power and the emergency source of electrical power; or

② the main source of electrical power, and a continuously charged dedicated accumulator battery of which the arrangement, location and endurance for power supply (18 h) are equivalent to those of the emergency source of electrical power. The battery may be an internal battery of the water level detector system;

(2) The changeover of supply from one source of electrical power to another need not be integrated into the water level detector system;

(3) Failure of any of the two electrical power supplies is to be indicated by an alarm.

2.19.2.10 The degree of protection provided by enclosures for electrical components installed in cargo holds, ballast tanks and dry spaces are to satisfy the requirements of IP 68.

2.19.2.11 Where the cargo hold is used as water ballast, sensors provided in the hold are to be suitable for the maximum pressure that might occur in the hold.

---

① See IEC publication 60079.

2.19.3 Installation requirements for water level detectors

2.19.3.1 The sensors are to be located in a protected position that is in communication with the specified part of the cargo hold (usually the aft part) such that the position of the sensor detects the level that is representative of the levels in the actual hold space. These sensors are to be located either as close to the centerline as practicable, or at both the port and starboard sides of the cargo hold.

The sensors are to be placed at a distance not exceeding 1 corrugation spacing or 1 bulkhead vertical stiffener spacing from the centerline, otherwise sensors are to be located at both the port and starboard sides of the cargo hold.

2.19.3.2 The sensors are to be located at the specified height. These heights are to be measured from the upper surface of the inner bottom. For bilge level sensors in 2.19.2.4(2) of this Section, if the bottom of the bilge well is below the upper surface of the inner bottom, the heights of those sensors are to be measured from the bottom of the bilge well.

2.19.3.3 When a lining or insulation is fitted, if the lining or insulation is not constructed to a watertight standard, then the height is to be measured from the upper surface of the inner bottom. If the lining or insulation is tested as watertight, then the heights may be measured from the upper surface of the lining/insulation.

2.19.3.4 The detector installation is not to inhibit the use of any sounding pipe or other water level gauging device for cargo holds or other spaces.

2.19.3.5 Detectors and equipment are to be installed where they are accessible for survey, maintenance and repair.

2.19.3.6 Any filter element fitted to detectors is to be capable of being cleaned before loading.

2.19.3.7 Electrical cables and any associated equipment installed in cargo holds are to be protected from damage by cargoes or mechanical handling equipment associated with bulk carrier operations, such as in tubes of robust construction or in similar protected locations.

2.19.3.8 Any change/modification to the ship’s structure, electrical systems or piping systems that involves cutting and/or welding are to be approved by ISC prior to commencement of work.

CHAPTER 3 CONSTRUCTION AND TESTING OF ELECTRICAL EQUIPMENT

Section 1 GENERAL PROVISIONS

3.1.1 General requirements

3.1.1.1 This Chapter applies to class-related electrical equipment. The additional requirements for high voltage electrical installations are given in Section 14, Chapter 2 of this PART, and additional requirements for electrical propulsion machinery are given in Chapter 15, PART EIGHT of the Rules.

3.1.1.2 Class-related electrical equipment is to be provided with certificates corresponding to its type. The specific requirements for certificates are given in Chapter 3, PART ONE of the Rules.

Section 2 ROTATING MACHINES

3.2.1 General requirements

3.2.1.1 The characteristics of the prime movers of generators and their governors are to comply with the relevant requirements of Chapters 7, 8 and 9, PART THREE of the Rules.

3.2.1.2 For generating sets operating in parallel, the governing characteristics of the prime mover are to be such as to ensure the load sharing specified in 3.2.7.5 and 3.2.8.5 of this Section. Facilities are to be provided to adjust the governor sufficiently fine to permit an adjustment of load not exceeding 5% of the rated load at normal frequency.

3.2.1.3 Shaft material for electrical propulsion motors and for main engine driven generators where the shaft is part of the propulsion shafting is to be certified by ISC.

3.2.1.4 Electrical machines are to be protected against ill effects of shaft current.

3.2.1.5 For non-closed-type bearings of electrical machines, consideration is to be to the fitting of grease cups or oil holes and corresponding oil drainage so as to ensure efficient lubrication.

3.2.2 Plans and documents

3.2.2.1 The following plans and documents are to be submitted for approval:

(1) General plan;

(2) Detailed drawings of main parts including assembly of stators, assembly of rotors, drawing of rotating shaft, assembly of slip rings or commutators, drawing of bedplate, and structural drawing of connection boxes;

(3) Technical specifications of the products;

(4) Front panel arrangement and system control flow diagram (applicable to electrical propulsion motors and their controls);

(5) Electrical schematic diagram (applicable to electrical generators and their excitation systems, electrical propulsion motors and their controls);

(6) External wiring diagram (applicable to electrical generators and their excitation systems, electrical propulsion motors and their controls).

3.2.2.2 The following plans and documents are to be submitted for information:

(1) Specifications of associated electrical appliances (applicable to electrical generators and their excitation systems, electrical propulsion motors and their controls).

3.2.3 Temperature rise

3.2.3.1 The limits of temperature rise of air-cooled machines based on an ambient air temperature of 45℃ are given in Table 3.2.3.1.

3.2.3.2 Where the ambient air temperature for motor operation is more than 45℃, the permissible temperature rise is to be reduced by an amount equal to the difference between the actual air ambient temperature and 45℃, based on the specified value given in Table 3.2.3.1.

Where the ambient air temperature for motor operation is less than 45℃, the permissible temperature rise is to be increased by a value equal to the difference between the actual ambient air temperature and 45℃, based on the specified value given in Table 3.2.3.1, and the increased value is not to be more than 15 K.

For motors fitted with water-cooled heat exchanger, the temperature of cooling water at the inlet of the heat exchanger may be regarded as the ambient air temperature for motor operation.

Limits of Temperature Rise (K) of Air-Cooled Machines **Table 3.2.3.1**

Thermal classification		B			F			H		
Method of measurement		Th	R	ETD	Th	R	ETD	Th	R	ETD
Item	Part of machine									
1a)	AC windings of machines having output of 5,000 kW (or kVA) or more	–	75	80	–	100	105	–	120	125
1b)	AC windings of machines having output above 200 kW (or kVA), but less than 5,000 kW (or kVA)	–	75	85	–	100	110	–	120	135
1c)	AC windings of machines having output of 200 kW (or kVA) or less, other than those of items 1d) or 1e)	–	75	–	–	100	–	–	120	–
1d)	AC windings of machines having rated output of less than 600 W (or VA)	–	80	–	–	105	–	–	125	–
1e)	AC windings and/or encapsulated windings of self-cooled machines without a fan (IC410)	–	80	–	–	105	–	–	125	–
2	Windings of armatures having commutators	65	75	–	80	100	–	100	120	–
3	Field windings of AC and DC machines other than those of item 4	65	75	–	80	100	–	100	120	–
4a)	Field windings of synchronous machines with cylindrical rotors having DC excitation windings embedded in slots, excluding synchronous induction motors	–	85	–	–	110	–	–	130	–
4b)	Stationary field windings of DC machines having more than one layer	65	75	85	80	100	110	100	120	135
4c)	Single-layer low-resistance field windings of AC and DC machines and compensating windings of DC machines having more than one layer	75	75	–	95	100	–	120	120	–
4d)	Single-layer windings of AC and DC machines with exposed bare or varnished metal surfaces and single-layer compensating windings of DC machines	85	85	–	105	110	–	130	130	–

Notes:
1) The temperature rise or the temperature of any part of machine is not to be detrimental to the insulation of that part or to any other part adjacent to it.
2) With application of the superposition test method to windings of machines in items 1c), 1d) and 1e) with insulation classes B and F, the limits of temperature rise given for the resistance method may be exceeded by 5 K.
3) Multi-layer windings are to comply with the requirements of item 4d) where the under layers are all in contact with the circulating primary coolant.
4) Th – thermometer, R – resistance, and ETD – embedded temperature detector.

3.2.3.3 Main and emergency generators, including their exciters, and continuously rated motors are to be suitable for continuous duty at their full rated output at maximum cooling air temperature for an unlimited period, without the limits of temperature rise in Table 3.2.3.1 being exceeded.
Other generators and motors are to be rated in accordance with the duty which they have to perform and when tested under rated load conditions, the temperature rise is not to exceed the values given in Table 3.2.3.1. For intermittent service S2 machines, the limits of temperature rise of windings may be 10 K above the values given in Table 3.2.3.1.

3.2.4 Sparking

3.2.4.1 Direct current motors and generators are to work with fixed brush setting from no load to the momentary overload specified without injurious sparking.
3.2.4.2 Alternating current commutator motors are to work over the specified range of load and speed without injurious sparking.

3.2.5 Overloads

3.2.5.1 Machines are to withstand, on test, the following overcurrents or excess torques without injury:
DC generators: 50% overcurrent for 15 s;
AC generators: 50% overcurrent for 2 min;
DC motors: 50% excess torque for 15 s;
Polyphase asynchronous motors: 60% excess torque for 15 s;
Polyphase salient synchronous motors: 50% excess torque for 15 s;
Polyphase non-salient synchronous motors: 35% excess torque for 15 s;
Polyphase synchronous motors of asynchronous construction (wound rotor): 35% excess torque for 15 s.

3.2.6 Short-circuits

3.2.6.1 Ship's service generators are to be capable of withstanding the mechanical and thermal effects of a short-circuit current for the duration of any time delay for discrimination purposes when tripping a protective device. AC generators and their excitation systems are to be capable of maintaining, under steady-state short-circuit conditions, a current of at least 3 times the full load rated current for a duration of 2 s or where precise data are available, for the duration of any time delay which may be provided by a tripping device.

3.2.6.2 For determining the discrimination settings in the distribution system where the generator is going to be used, the generator manufacturer is to provide documentation showing the transient behaviour of the short circuit current upon a sudden short-circuit occurring when excited, and running at nominal speed. The influence of the automatic voltage regulator is to be taken into account, and the setting parameters for the voltage regulator are to be noted together with the decrement curve. Such a decrement curve is to be available when the setting of the distribution system's short-circuit protection is calculated. The decrement curve need not be based on physical testing. The manufacturer's simulation model for the generator and the voltage regulator may be used where this has been validated through the previous type test on the same model.

3.2.7 DC generators

3.2.7.1 All DC generators other than charging generators are, in general, to be of compound-wound or shunt-wound with automatic voltage regulator, or stabilized shunt-wound (shunt-wound with few turns of series windings).

3.2.7.2 Manual voltage regulators are to be provided at the control panel to enable the voltage of each DC generator to be adjusted separately. For each DC generator, at any temperature within the working range and at any load between no load and full load, and when the voltage varies from 80% to 105% of the rated value, the accuracy of voltage adjustment is to be as follows:
(1) 0.5% of rated voltage for generators of rating exceeding 100 kW;
(2) 1.0% of rated voltage for generators of rating not exceeding 100 kW.
The circuit of manual voltage regulators is in general to be capable of being opened and means are to be provided to protect against over-voltage when the circuit is opened. Non-opened circuit is permitted only in such a case where the manual voltage regulator could adjust the no-load voltage to a value approaching to the remanence voltage.
The handwheel of manual voltage regulators is to be so arranged that when it is turned clockwise, the generator voltage will rise and vice versa.

3.2.7.3 Equalizer leads are to have a cross-sectional area appropriate to the system but in no case less than 50% of that of the negative lead from the generator to the switchboard.

3.2.7.4 For compound-wound generators rated at 50 kW and over, at full load operating temperature and with due regard being paid to governing characteristics of the prime mover, the voltage regulation characteristics are to be such that voltage variations are within 1% of the rated voltage for 20% of the rated load, that voltage variations are within 2.5% of the rated voltage for the full rated load and that the average of the ascending and descending curves of voltage regulation characteristics between 20% load and full load does not vary more than 3% from the rated voltage.

3.2.7.5 All DC generating sets arranged to run in parallel are to be stable in operation. When the combined load on the sets is varied between 20% and 100% of the combined ratings, the individual load on each machine is not to differ from the theoretical load (proportional to rating) by an amount greater than:
(1) ±12% of the rated full load of the largest machine; or
(2) ±25% of the rating of the smallest machine when the rating of the smallest machine is less than 50% of that of the largest one.
Such a load sharing is not to result in overloading the smaller set.

3.2.8 AC generators

3.2.8.1 Each AC generator, unless of the self-regulated type, is to be provided with separate automatic and manual voltage regulators at the generator control panel.
3.2.8.2 Each AC generator driven by the prime mover having governing characteristics complying with Chapter 7, 8 or 9, PART THREE of the Rules together with its excitation system is to be capable of maintaining the voltage under steady conditions within ±2.5% of the rated voltage from zero to full load at rated power factor. These limits may be increased to ±3.5% for emergency generators.
3.2.8.3 When the generator is driven at rated speed and a voltage close to its rated voltage on no-load, and is subjected to a sudden change of symmetrical load within the limits of 60% of the rated current with a power factor not exceeding 0.4 (lagging), the transient voltage is not to fall below 85% nor exceed 120% of the rated voltage. The voltage of the generator is then to be restored to within plus or minus 3% of the rated voltage in not more than 1.5 s. For emergency generators, these values may be increased to plus or minus 4% of the rated voltage in not more than 5 s, respectively.
3.2.8.4 For AC generators, the sinusoidal distortion of the voltage waveform under no-load conditions is not to exceed 5%, except for small (e.g. less than 24 kW) generators.
3.2.8.5 All AC generating sets arranged to run in parallel are to be stable in operation. In the range between 20% and 100% of the combined rated load of all generators, the load sharing is to be as follows:
(1) The active load on any individual generator is not to differ from the proportionate share of the total active load by more than the lesser of the following:
① ±15% of the rated active output of the largest generator; or
② ±25% of the rated active output of the individual generator.
Facilities are to be provided to adjust the governor of the prime mover sufficiently fine to permit an adjustment of load not exceeding 5% of the rated load at normal frequency.
(2) The reactive load on any individual generator is not to differ from the proportionate share of the total reactive load by more than the lesser of the following:
① ±10% of the rated reactive output of the largest generator;
② ±25% of the rated reactive output of the smallest generator.

3.2.9 Testing
3.2.9.1 All electrical machines are to be tested by the manufacturer according to IEC Publication 60092-301. Manufacturer's test records are to be provided for machines for essential services.
3.2.9.2 All machines of 50 kW and over, intended for essential services, are to be surveyed by ISC Surveyors during test and, if appropriate, during manufacturing. ISC and the manufacturer may agree on an alternative survey plan which makes Surveyor's attendance in accordance with the requirements above unnecessary.
3.2.9.3 Items for type and routine tests of the electrical machines are to be in compliance with Table 3.2.9.3. Test requirements may differ for shaft generators, special purpose machines and machines of novel construction.

Items for Type and Routine Tests of Electric Machines **Table 3.2.9.3**

No	Tests	AC Generators		Motors	
		Type test①	Routine test②	Type test①	Routine test②
1	Examination of the technical documentation, as appropriate and visual inspection	×	×	×	×
2	Insulation resistance measurement	×	×	×	×
3	Winding resistance measurement	×	×	×	×
4	Verification of the voltage regulation system	×	×③		
5	Rated load test and temperature rise measurements	×		×	
6	Overload/overcurrent test	×	×④	×	×④
7	Verification of steady short circuit conditions⑤	×			
8	Overspeed test	×	×	×⑥	×⑥
9	Dielectric strength test	×	×	×	×
10	No-load test	×	×	×	×
11	Verification of degree of protection	×		×	
12	Verification of bearings	×	×	×	×

Notes: ① Type tests on prototype machine or tests on at least the first batch of machines.
② The report of machines routine tested is to contain the manufacturer's serial number of the machine which has been type tested and the test result.
③ Only functional test of voltage regulator system.
④ Only applicable for machines of essential services rated above 100 kW.

⑤ Verification of steady short circuit condition applies to synchronous generators only.
⑥ Not applicable for squirrel cage motors.

3.2.9.4 The tests required in Table 3.2.9.3 are to be in accordance with the requirements in 3.2.9.5 to 3.2.9.15, in addition to complying with the relevant requirements of acceptable standards①.

3.2.9.5 Visual inspection

A visual examination is to be made of the machine to ensure, as far as is practicable, that it complies with submitted technical documentation.

3.2.9.6 Insulation resistance measurement

Immediately after the high voltage tests the insulation resistances are to be measured using a direct current insulation tester (DC megameter) between:

(1) all current carrying parts connected together and earth;

(2) all current carrying parts of different polarity or phase, where both ends of each polarity or phase are individually accessible.

The minimum values of test voltages and corresponding insulation resistances are given in Table 3.2.9.6. The insulation resistance is to be measured close to the operating temperature, or an appropriate method of calculation is to be used.

Minimum Test Voltage and Minimum Insulation Resistance Value Table 3.2.9.6

Related voltage U_n (V)	Minimum test voltage (V)	Minimum insulation resistance (MΩ)
$U_n \leq 250$	$2 \times U_n$	1
$250 < U_n \leq 1{,}000$	500	1
$1{,}000 < U_n \leq 7{,}200$	1,000	$(U_n/1{,}000) + 1$
$7{,}200 < U_n \leq 15{,}000$	5,000	$(U_n / 1{,}000) + 1$

3.2.9.7 Winding resistance measurement

The resistances of the machine windings are to be measured and recorded using an appropriate bridge method or voltage and current method.

3.2.9.8 Verification of voltage regulation system

Verification results are to meet the requirements in 3.2.8.2 and 3.2.8.3 of the Section. Subject to agreement of ISC, such voltage regulation during transient conditions may be calculated values based on the previous type test records, and need not be tested during factory testing of a generator, however the calculation report is to be submitted by the manufacturer to demonstrate that the requirements of 3.2.8.3 are met.

3.2.9.9 Rated load test and temperature rise measurements

The temperature rises are to be measured at the rated output, voltage, frequency and the duty for which the machine is rated and marked in accordance with the testing methods specified in IEC Publication 60034-1, or by means of a combination of other tests. Temperature rise is to be measured after the test and the limits of temperature rise are those specified in Table 3.2.3.1.

3.2.9.10 Overload/over-current tests

Electrical machines are to be able to withstand the overload/over-current tests as required in 3.2.5.1 of this Section after the rated load test. The overload test can be replaced at routine test by the over-current test.

3.2.9.11 Verification of steady short-circuit conditions

Verification of AC synchronous generators and their excitation systems is to be in accordance with the requirements in 3.2.6.1, 3.2.6.2 of this Section.

3.2.9.12 Overspeed test

Machines are to withstand the overspeed test as specified in IEC Publication 60034-1. This test is not applicable for squirrel cage motors.

3.2.9.13 Dielectric strength test

Machines are to withstand a dielectric test as specified in IEC Publication 60034-1. For high voltage machines an impulse test is to be carried out on the coils according to 2.14.3.3 of this PART.

3.2.9.14 No load test

Machines are to be operated at no load and rated speed whilst being supplied at rated voltage and frequency as a motor or if a generator it is to be driven by a suitable means and excited to give rated terminal voltage. During the running test, the vibration of the machine and operation of the bearing lubrication system, if appropriate, are to be checked.

3.2.9.15 Verification of degree of protection

---

① Refer to IEC Publication 60092-301: Electrical installations in ships – Part 301: Equipment – Generators and motors and IEC Publication 60034-1: Rotating electrical machines – Part 1: Rating and performance, or other equivalent standards.

As specified in the standards acceptable to ISC①.

3.2.9.16 Verification of bearings

Upon completion of the above tests, machines which have sleeve bearings are to be opened to establish that the shaft is correctly seated in the bearing shells.

Section 3 SWITCHGEAR ASSEMBLIES

3.3.1 Plans and documents

3.3.1.1 The following plans and documents are to be submitted for approval:

(1) General plan;

(2) Front panel arrangement;

(3) Technical specifications of the products;

(4) Electrical schematic diagram.

3.3.1.2 The following plans and documents are to be submitted for information:

(1) Specifications of associated electrical appliances;

(2) Operation instructions for the products (which may be omitted if they are covered in other plans and documents for switchgear assemblies);

(3) External wiring diagram.

3.3.2 Design and construction of switchgear assemblies

3.3.2.1 The construction of main and emergency switchboards is to satisfy the following requirements:

(1) The top of switchboards is to have a degree of protection of IP22, and where the switchboard is installed in the control room complying with the requirements of 2.1.4.2 of this PART, a protection of IP21 at the top may be accepted. The sides of switchboards are to have at least a degree of protection of IP2X. For switchboards having a rated voltage in excess of 500 V, a protection of at least IP2X at the rear is to be provided.

(2) For switchboards having a voltage to earth or a working voltage above 50 V, exposed live parts are not to be installed on the front.

(3) Insulated handrails are to be provided at the front of all main and emergency switchboards. Where access to the rear of above-mentioned switchboards is necessary for operational or maintenance purposes, an insulated handrail is to be fitted on the rear. And horizontal insulated handrails are to be fitted on a fixed part of the switchboard.

(4) Provision is to be made at the cable entry to switchboards so that there is no water leakage into the switchboard along the cables.

(5) The main bus-bar is to be subdivided in accordance with the requirements in 2.1.1.1(5) of this PART.

(6) Where the total capacity of the main generating sets exceeds 100 kVA, a separate cubicle is to be provided for each generator, and the cubicles are to be separated from each other by partitions of steel or flame-retardant material.

(7) Terminals for systems having a rated voltage above 500 V are to be separated from terminals for lower voltages and are to be clearly marked.

3.3.2.2 Section and distribution boards are to be enclosed according to Table 1.3.2.2 of this PART. All enclosures are to be constructed of flame-retardant and non-hygroscopic material, and are to be of robust construction.

3.3.2.3 The arrangement of protection of electrical installations and the choice of protective devices are to comply with the relevant requirements of Section 5 of Chapter 2 of this PART.

3.3.2.4 All instruments, switchgear, pilot lamps, push buttons, operating handles or handwheels fitted on switchboards are to be provided with durable labels indicating their purposes and operating positions.

3.3.2.5 A durable label indicating the purpose of each circuit and the rating or appropriate setting of its overload protective device is to be provided at the location of the protective device. For fuses above 500 V where the fuse holders permit the insertion of fuses for lower rated voltages, special warning labels are to be placed, for example, “CAUTION: 660 V FUSES ONLY!”.

3.3.2.6 Devices for monitoring the insulation level to earth, which are in compliance with the requirements of 2.4.2.2 of this PART, are to be provided on the main and emergency switchboards.

3.3.2.7 Pilot lamps are to be provided at the generator control panels to indicate whether the generator circuit breakers are at the on or off position. Where a space heater is provided for the generator, a pilot lamp

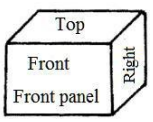
---

① Refer to IEC Publication 60034-5 Rotating electrical machines – Part 5: Degrees of protection provided by the integral design of rotating electrical machines (IP code) – Classification, or other equivalent standards.

indicating the operation of the space heater is to be provided at the control panel.
3.3.2.8 Means are to be provided at the control panel of DC generators to enable the voltage to be regulated in accordance with the requirements of 3.2.7.2 of this PART.
3.3.2.9 For each AC generator arranged to operate in parallel, a remote control device is to be provided at the control panel to enable the speed of the prime mover to be adjusted within 10% of its rated value.
3.3.2.10 Means are to be provided at the control panel for magnetization of the DC generator.
3.3.2.11 Shore connection boxes of shore supply or other external sources are to be provided with the following:
(1) suitable terminals for connecting the flexible cables;
(2) an earth terminal for connecting the hull to the shore;
(3) switches with necessary protection complying with the requirements of 2.5.9.5 of this PART;
(4) a lamp or voltmeter to indicate the terminal voltage;
(5) means for checking the polarity (for direct current) or the phase sequence (for three-phase AC) of the incoming supply in relation to the ship's system;
(6) means to prevent the imposing of excessive mechanical forces on cable terminals;
(7) a nameplate giving full information on the system of supply, the rated voltage and frequency (for AC) of the ship's system.
3.3.2.12 The charging facilities of battery charging and discharging boards for the emergency or transitional source of electrical power are to comply with the requirements of 2.11.3 of this PART.
3.3.2.13 A disconnect switch and a indicator light for power supply are to be provided on battery charging and discharging boards for the emergency or transitional source of electrical power.

3.3.3 Bus-bars

3.3.3.1 Bus-bars are to be made of conducting cathode copper or copper-sheeted aluminium alloy. The maximum permissible temperature rise for bus-bars is 45 K.
3.3.3.2 Bus-bars and their supports are to be designed to withstand the mechanical stresses which will arise during short-circuits.
3.3.3.3 Bare main bus-bars in main and emergency switchboards (excluding the conductors between the main bus-bar and the supply side of outgoing units) are to have the minimum clearances and creepage distances as given in Table 3.3.3.3.



Minimum Clearances and Creepage Distances **Table 3.3.3.3**

Rated voltage (V)	Minimum clearance (mm)	Minimum creepage distance (mm)
$U_n \leq 250$	15	20
$250 < U_n \leq 690$	20	25
$U_n > 690$	25	35

Note: Values given in the Table apply to clearances and creepage distances between live parts as well as between live parts and exposed conductive parts.

3.3.3.4 The current rating of equalizer bus-bars is not to be less than 50% of the rated full load current of the largest generator in the generating plant.
3.3.3.5 The cross sectional area of neutral bus-bar in AC three-phase four-wire systems are not to be less than 50% of that of the bus-bar in the corresponding phase.
3.3.3.6 The arrangement of bus-bars in the switchboard as per the phase sequence (DC) or the polarity (AC) is to be arranged in accordance with Table 3.3.3.6 (as viewed from the front of the assembly).

Arrangement per Phase Sequence or Polarity **Table 3.3.3.6**

Bus bar	Phase sequence or polarity	Position of bus bars			Sketch
		Vertically	Horizontally	Outgoing	
AC	1st phase	Top	Front	Left	As viewed from the front of switchboard assembly 
	2nd phase	Middle	Middle	Middle	
	3rd phase	Bottom	Back	Right	
DC	Positive pole	Top	Front	Left	
	Equalizer pole	Middle	Middle	Middle	
	Negative pole	Bottom	Back	Right	

Note: AC neutral bus-bars may be located at suitable positions.

3.3.4 Measuring instruments

3.3.4.1 The precision grade of instruments is to be selected according to the service of the instruments, but in no case is the precision grade to be inferior to 1.5.
3.3.4.2 The range and scale of the measuring instruments are to comply with the following requirements:
(1) The upper limit of the scale of every voltmeter is to be approximately 120% of the normal voltage of the circuit.
(2) The upper limit of the scale of every ammeter is to be approximately 130% of the normal rating of the circuit in which it is installed.
(3) The upper limit of the scale of every wattmeter is to be approximately 120% of the normal rating of the circuit in which it is installed. Ammeters for use with direct current generators operating in parallel and wattmeters for use with alternating current generators operating in parallel are to be capable of indicating 15% reverse current or power respectively.
(4) The frequency meter is to have a scale range of approximately ±10% of the rated frequency.
(5) Ammeters, voltmeters and wattmeters are to be clearly marked on the scale to indicate their rated values.
3.3.4.3 Generator control panels are to be provided at least with the measuring instruments as required in Table 3.3.4.3.
3.3.4.4 The secondary windings of potential and current transformers are to be effectively earthed.
3.3.4.5 At least the following meters are to be provided for battery charging and discharging boards for emergency or transitional sources of power:
(1) voltmeter to measure the charging voltage;
(2) ammeter to measure the charging current.

Measuring Instruments of Generator Control Panel **Table 3.3.4.3**

Generator	Operating condition	Type of instrument	Quantity
DC	Not in parallel	Ammeter	1 for each generator (connected to positive pole)
		Voltmeter	1 for each generator
	In parallel	Ammeter	1 for each generator (connected to positive pole)
		Voltmeter	2 (1 for measuring the bus-bar voltage, 1 for measuring the voltage of each generator)
AC	Not in parallel	Ammeter	1 for each generator (to be capable of measuring the current in each phase or each line separately)
		Voltmeter	1 for each generator (to be capable of measuring the voltage in each phase or each line separately)
		Wattmeter	1 for each generator (excluding generators rated less than 50 kW (kVA))
		Frequency meter	1 for each generator
		Excitation ammeter	1 for each generator (to be fitted only when necessary)
	In parallel	Ammeter	1 for each generator (to be capable of measuring the current in each phase or each line separately)
		Voltmeter	2 (1 for measuring the voltage in each phase or each line of the generator separately, 1 for measuring the bus-bar voltage)
		Wattmeter	1 for each generator
		Frequency meter	2 (1 for measuring the bus-bar voltage, 1 for measuring the frequency of each generator)
		Synchronous meter	1 for all generators
		Excitation ammeter	1 for each generator (to be fitted only when necessary)

3.3.5 Circuit breakers and switches

3.3.5.1 Circuit breakers are to be designed, manufactured and tested in accordance with IEC Publication 60947-2 or other recognized standards. Circuit breakers are to be of the trip-free type.
3.3.5.2 Circuit breakers and switches are to be so arranged that when in the OFF position, they cannot accidentally move to close the circuit.
3.3.5.3 The protective performance of circuit breakers for generators is to comply with the requirements of 2.5.6 of this PART. The overcurrent trip setting of these circuit breakers is to be adjustable, or if not adjustable, the set values are to be readily replaceable by different ones.
3.3.5.4 Where circuit breakers are operated by a power operating device, a hand operated mechanism is to be provided to operate the circuit breaker in case of failure of the electrical driven gear. For AC main switchboard of less than 1 kV in rated voltage, the generator circuit breaker is to be operated at the front of panels without opening the panel.
3.3.5.5 The fused circuit breakers are to be so constructed that single phasing does not occur in the event

of blowing of fuses and that the fuses can be replaced easily without the risk of accidental touch to their live parts.
3.3.5.6 Durable labels are to be fitted on circuit breakers to indicate their rated voltage, and the rated current and setting of their overcurrent trip devices, etc.

3.3.6 Fuses
3.3.6.1 Fuses are to be designed, manufactured and tested in accordance with IEC Publication 60269 or other recognized standards.
3.3.6.2 Fuses are to be of enclosed type and the construction is to be such that the enclosure is not broken or burnt and the adjacent insulation is not deteriorated by melted metal or emitted gases, when the fuse element has blown out.
3.3.6.3 Fuses are to be easily replaceable for their spare parts without the risk of getting electrical shock or burn on removing and replacing of fuses.
3.3.6.4 When fuses are operating for long periods at rated current, the temperature rise at the terminals is to be such that the maximum permissible operating temperature of the connected cable is not exceeded.
3.3.6.5 Fuses are to be durably marked to indicate their rated voltage, rated current and rated breaking capacity.

3.3.7 Testing
3.3.7.1 Switchboards are to be tested at the manufacturer in accordance with the provisions of 3.3.7.2 to 3.3.7.5 of this Section. However, the test required in 3.3.7.2 may be omitted for batch products of the same type.
3.3.7.2 Switchboards are to be subjected to temperature rise test at the specified load current.
3.3.7.3 Switchboards are to be subjected to functional testing for verifying the function of instruments and switchgear.
3.3.7.4 Switchboards are to be subject to high voltage test as required in Table 3.3.7.4. The test voltage may be applied at any frequency between 25 and 100 Hz and is to be maintained for one minute without breakdown. Instruments and ancillary apparatus may be disconnected during the test.

Test Voltage **Table 3.3.7.4**

Rated voltage (V)	Test voltage a.c. r.m.s.(V)	Test voltage d.c.(V)
$U_n \leq 60$	1000	1415
$60 < U_n \leq 300$	1500	2120
$300 < U_n \leq 690$	1890	2670
$690 < U_n \leq 800$	2000	2830
$800 < U_n \leq 1{,}000$	2200	3110
$1{,}000 < U_n \leq 1{,}500$①	——	3820

Notes: ① For DC only.
② During testing all semi-conductor component parts are to be disconnected from the circuits to be tested and in the meantime, the measuring instruments, condensers, pilot lamps and other ancillary apparatus may also be disconnected.
③ The test voltage is to be applied between all current carrying parts and earthed enclosure, and between current carrying parts of different polarity or phase.

3.3.7.5 Insulation resistance measurement: Immediately after the high-voltage test, the insulation resistance between all current-carrying parts connected together and earth and between all current-carrying parts of different polarity or phase is not to be less than 1 MΩ, tested at least with a DC 500 V megameter.

Section 4 CONTROL GEAR

3.4.1 General requirements
3.4.1.1 The operating wheels or handles of the control gear are to comply with the following requirements:
(1) The temperature is not to exceed 55℃ for those made of metal , and not to exceed 65℃ for those made of insulating material.
(2) They are to be provided with mechanically locking devices so that their operating positions will not be changed due to shock or vibration.

(3) They are to be provided with durable labels to indicate their purposes, positions and effect of movement.
3.4.1.2 The hand wheels of the control gear are to be arranged to rotate clockwise to "raise", "heave anchor", "haul in rope", and counterclockwise to "lower", "drop anchor", "pay out rope", if position "0" is the starting point.
The handles of control gear are to be arranged to move forward to "lower", "drop anchor", "pay out rope", and counterclockwise to "raise", "heave anchor", "haul in rope", if position "0" is the starting point.
3.4.1.3 The control gear is to be provided with protective devices complying with the relevant requirements of Section 5, Chapter 2 of this PART.
3.4.1.4 Suitable means are to be provided for the control push buttons against wrong action due to inadvertent touching.
3.4.1.5 Parallel field windings which allow an open circuit are to be provided with discharge circuits to protect against induced overvoltage.

3.4.2 Plans and documents
3.4.2.1 The following plans and documents are to be submitted for approval:
(1) General plan;
(2) Detailed drawings of main parts;
(3) Technical specifications of the products;
(4) Electrical schematic diagram.
3.4.2.2 The Operation Instructions for the Products is to be submitted for information.

3.4.3 Motor control gear
3.4.3.1 The motor control gear is to be provided with an indicating device to show that the motor is running.
3.4.3.2 The control gear of motors used for various services is also to comply with the relevant requirements of Section 6, Chapter 2 of this PART. The control gear of the steering gear is also to comply with the relevant requirements of Chapter 13, PART THREE of the Rules.
3.4.3.3 The control gear of windlasses, warping winches, and cargo winches is to be provided with a device for emergency disconnection of the circuits.
3.4.3.4 Where windlass motors and warping winch motors have rating equal to or more than 10 kW, their control gears are to be provided with an ammeter to monitor the operating current of the motors, and this ammeter is to be properly illuminated or to be of fluorescent type.

3.4.4 Testing
3.4.4.1 Temperature rise test: Control gear is to be subjected to temperature rise test under normal working conditions. However, for the products of the same type and the same specification, only the first product is required to be tested.
3.4.4.2 Functional test: All control gears are to be subjected to functional testing.
3.4.4.3 High voltage test: The test is to be carried out according to Table 3.3.7.4. The test voltage may be applied at any frequency between 25 and 100 Hz and is to be maintained for one minute without breakdown. Instruments and ancillary apparatus may be disconnected during the test.
3.4.4.4 Insulation resistance test: Immediately after the high voltage test, the insulation resistance is not to be less than 1 MΩ, tested at least with a DC 500 V megameter.

Section 5 CABLES

3.5.1 General requirements
3.5.1.1 Cables are to comply with the requirements of this Section. Those not covered in this Section are to comply with the relevant requirements of acceptable standards①. Fire-resisting cables are to additionally comply with the relevant requirements for fire-resisting cables of acceptable standards②.

---

① Refer to IEC publications 60092-350, 60092-352, 60092-353, 60092-354, 60092-360, 60092-370 and 60092-376.
② Refer to:
IEC publication 60331-1 for testing electric cables of greater than 20 mm overall diameter;
IEC publication 60331-21 or 60331-2 for testing electric cable of up to 20 mm overall diameter;
IEC publication 60331-23 for testing electric data cables;
IEC publication 60331-25 for testing optical fibre cables.

3.5.1.2 Cables manufactured and tested to standards other than those specified in 3.5.1.1 will be accepted provided they are in accordance with an acceptable and relevant international or national standard and are of an equivalent or higher safety level than those listed in 3.5.1.1. However, cables such as flexible cable, fibre-optic cable, etc., used for special purposes may be accepted provided they are manufactured and tested in accordance with the relevant standards accepted by ISC.
3.5.1.3 Structural drawings and technical specifications of cables are to be submitted for approval.

3.5.2 Conductors

3.5.2.1 Conductors are to be of annealed copper with or without metal coating. The component copper wires are to be metal-coated and the wire surface is to appear smooth, uniform and bright when used for conductors having a thermosetting insulation, unless a separator between the conductor and the insulation is provided. The same applies to thermosetting insulation provided suitable type tests demonstrate that no harmful effects occur.
3.5.2.2 Conductor composition and stranding is to be according to IEC 60028 class 2 or class 5 and that adequate flexibility of the finished cable is assured. Cores of multi-core cables are to be readily identifiable.

3.5.3 Insulating materials

3.5.3.1 Permitted insulating materials and maximum rated conductor temperatures are to comply with the requirements of 2.12.2.2 of this PART. Insulating materials are to comply with the provisions of IEC60092-360.

3.5.4 Sheaths

3.5.4.1 The sheath is to be selected from one of those listed in IEC 60092-360 as specified in Table 3.5.4.1.

Sheath Materials **Table 3.5.4.1**

Type of materials		Remarks
Cross-linked material	Polychloroprene rubber	Suitable for use on insulating materials other than cross-linked polyethylene (XLPE); harmful smoke is released in case of fire.
	Chlorosulphonated polyethylene or chlorinated polyethylene rubber	
	Halogen-free rubber	——
Thermoplastic material	Polyvinyl chloride thermoplastic compound	Harmful smoke is released in case of fire.
	Halogen-free thermoplastic compound	——

3.5.4.2 Metal braid armour is to be made of galvanized steel, copper or copper alloy wires. The coverage density of the braid is to be such that the weight of the braid is at least 90% of the weight of a tube of the same metal, having an internal diameter equal to the internal diameter under the braid and a thickness equal to the nominal diameter of the wires forming the braid.
3.5.4.3 A protective bedding is to be inserted beneath armour (of any type). This may be textile tape or braid, chloroprene rubber tape or other suitable material. Textile materials are to be treated against moisture. The bedding is to be compatible with the operating temperature of the cable. It is to be possible to remove the bedding without damaging the underlying part.

3.5.5 Testing

3.5.5.1 Tests in accordance with the relevant acceptable standards① are to be made at the manufacturer prior to delivery.

Section 6 POWER AND LIGHTING TRANSFORMERS

3.6.1 General requirements

3.6.1.1 The requirements of this Section apply to single phase transformers rated at 1 kVA or more and 3-phase transformers rated at 5 kVA or more.

---

① Refer to IEC Publication 60092 or relevant standards.

3.6.1.2 All transformers, except those used for motor starting, are to be double wound or multi wound, with no electrical connection between primary and secondary windings.
3.6.1.3 In general, transformers are to be of dry air-cooled type. The use of liquid-filled transformers is to comply with the following requirements:
(1) Liquid fillings for transformers are to be non-toxic and of a type which does not readily support combustion. Such transformers are to have a pressure release device with an alarm and there is to be a suitable means provided to contain any liquid which may leak from the transformer due to the operation of the release device or damage to the tank.
(2) Where forced liquid cooling is used, there is to be temperature monitoring of the cooling medium and transformer windings with an alarm being given when the temperature exceeds a preset limit, and provision is to be made for reducing the load to a level commensurate with the cooling available.
3.6.1.4 Transformers rated at 50 kVA and over are to be inspected by ISC Surveyors during testing and where necessary, during manufacturing.

3.6.2 Plans and documents

3.6.2.1 The following plans and documents are to be submitted for approval:
(1) General plan;
(2) Detailed drawings of main parts including coils, magnetic cores and connection boxes;
(3) Technical specifications of the products.
3.6.2.2 The following plans and documents are to be submitted for information:
(1) Operation instructions for the products;
(2) External wiring diagram.

3.6.3 Voltage regulation

3.6.3.1 The voltage drop of transformers supplying secondary distribution systems from no load to rated load at resistive load is not to exceed the following:
(1) 2.5% for single phase transformers rated more than 5 kVA or 3-phase transformers rated more than 15 kVA;
(2) 5% for single phase transformers rated up to 5 kVA or 3-phase transformers rated up to 15 kVA.

3.6.4 Temperature rise

3.6.4.1 The temperature rise of transformers at any part is not to exceed the values given in Table 3.6.4.1 during continuous operation at rated output, where the ambient air temperature is based on 45℃.

Limit of Temperature Rise **Table 3.6.4.1**

Part of transformer		Limit of temperature rise (K)	Method of measurement
Windings	Class A insulation	55	Resistance method
	Class E insulation	70	
	Class B insulation	75	
	Class F insulation	95	
	Class H insulation	120	
External surface of the magnetic core and structural components		Not to exceed the permissible temperature rise of the insulating material in contact	Thermometer or thermocouple

3.6.5 Short-circuits

3.6.5.1 All transformers are to be capable of withstanding, without damage, the thermal and mechanical effects of a short-circuit at the terminals of any winding for 2 s.

3.6.6 Tests

3.6.6.1 Performance tests (winding resistance measurement, voltage ratio measurement and check of phase displacement, short-circuit impedance and load loss measurement, no-load loss and no-load current measurement, etc.) are to to be carried out to all transformers at the manufacturer and in addition to the tests in 3.6.6.2 to 3.6.6.5 of this Section as a minimum, relevant tests are to be carried out in accordance with the requirements of IEC 60076 series publication and equivalent standards. However, the test required in 3.6.6.2 may only be carried out to the first product for batch products of the same type and specification.
3.6.6.2 Temperature rise test: Transformers are to be tested for temperature rise at rated output or in accordance with accepted standards[①]. The limits of temperature rise are not to exceed the values given in

① Refer to publications of IEC 60076 series or equivalent standards.

Table 3.6.4.1.

3.6.6.3 High voltage test[①②]: Transformers are to be subjected to high voltage test according to Table 3.6.6.3, applying a test voltage between primary and secondary windings and between windings and the earthed enclosure for 1 min without breakdown and flashover.

Voltage of High Voltage Test **Table 3.6.6.3**

Highest voltage (root-mean-square value) kV	Rated short duration power frequency withstand voltage (root-mean-square value) kV
≤ 1.1	3
3.6	10
7.2	20
12.0	28
17.5	38
24.0	50
36.0	70

3.6.6.4 Induced high voltage test: Transformers are to withstand an induced high voltage test with a voltage twice the rated voltage. The duration of the test is to be 1 min with a frequency less than or equal to twice the rated frequency. If the frequency is greater than twice the rated frequency, the duration of the test is to be obtained from the following formula with a minimum of 15 s:

$$t = \frac{60 \times 2 \times \text{rated frequency}}{\text{test frequency}} \quad \text{s}$$

For transformers subject to temperature rise test, the induced high voltage test is to be carried out immediately after the temperature rise test.

3.6.6.5 Insulation resistance test: The insulation resistance of each winding to earth is to be measured, with all other windings, magnetic core, frame and casing or enclosure connected together to earth, and recorded together with the temperature of the transformer at the test.

Section 7 STORAGE BATTERIES

3.7.1 General requirements

3.7.1.1 This Section is applicable to the permanently installed batteries.

3.7.2 Plans and documents

3.7.2.1 The following plans and documents are to be submitted for approval:

(1) General plan;

(2) Detailed drawings of main parts including enclosures and pole plates;

(3) Technical specifications of the products.

3.7.2.2 The Operation Instructions for the Products is to be submitted for information.

3.7.3 Type

3.7.3.1 Storage batteries used on board ships may be of lead-acid or nickel-alkaline type. Other types of batteries are not to be put on board ships without agreement of ISC.

3.7.4 Construction

3.7.4.1 All pole plates are to be of rigid construction, and are to be designed to reduce the shedding of active material to a minimum. The cells are to be so constructed as to prevent spilling of electrolyte due to an inclination of 40° from the normal, and to prevent emission of acid or alkaline spray.

3.7.4.2 The cells are to be grouped in crates or trays of rigid construction and suitable material and equipped with means to facilitate handling. The weight of the assembled batteries is preferably not to exceed 100 kg. This requirement does not apply to the cells the assembly of which in the above-mentioned crates or trays is impossible due to their weight.

3.7.4.3 Emergency accumulator batteries are to be so designed and arranged as to ensure that they will

---

① For transformers subject to temperature rise test, the high voltage test is to be carried out immediately after the temperature rise test.

② The high voltage test is in general not to be repeated, but if it is necessary, one additional test is permitted to be carried out with a test voltage equal to 75% of the voltage at the first test.

function at full rated power when the ship is upright or when inclined at any angle of list up to 22.5° or when inclined up to 10° either way in the fore or aft direction, or is in any combination of angles within those limits.

3.7.5 Nameplate

3.7.5.1 Each crate or tray is to be provided with a durable nameplate securely attached, indicating the manufacturer's name, type designation, voltage and the ampere-hour rating at a specific rate of discharge (preferably that corresponding to the duty for the specific application 5 h, 10 h or 20 h rating).

Section 8 POWER SEMICONDUCTOR CONVERTORS

3.8.1 General requirements

3.8.1.1 This Section is applicable to power semiconductor convertors using semiconductor rectifying elements such as diodes, reverse blocking triode thyristors etc., and does not apply to convertors for communication and the ancillary apparatus for instrumentation. The conversion may be from AC to DC, from DC to AC, from DC to DC and from AC to AC.

3.8.1.2 Unless otherwise specified by the manufacturer, the maximum permissible junction temperature of the rectifier cells is not to exceed the following values:

Selenium diodes: 70℃;
Silicon diodes: 150℃;
Silicon thyristor: 100℃ (up to 50 A);
125℃ (more than 50 A).

3.8.1.3 Semiconductor convertors are preferably to be of the dry air-cooled type.

3.8.1.4 Liquid-filled semiconductor convertors are preferably to be hermetically sealed. If provision is made for breathing, suitable desiccants are to be provided.

3.8.1.5 Transformers used in combination with semiconductor convertors are to be of two-winding transformers and are to comply with the relevant requirements of Section 6 of this Chapter.

3.8.1.6 Semiconductor convertors or semiconductor components are to be mounted in such a manner that they may be removed from a unit without dismantling the complete unit.

3.8.1.7 Mercury-based fungicides are not to be used in the vicinity of the selenium rectifiers.

3.8.2 Plans and documents

3.8.2.1 The following plans and documents are to be submitted for approval:

(1) General plan;
(2) Electrical schematic diagram;
(3) Technical specifications of the products.

3.8.2.2 The following plans and documents are to be submitted for information:

(1) External wiring diagram;
(2) Specification list of associated electrical appliances;
(3) Operation instructions for the products.

3.8.3 Protection

3.8.3.1 Where forced cooling is provided, the circuit is to be so designed that the convertor cannot remain in operation unless effective cooling is maintained.

3.8.3.2 Semiconductor convertors are to be capable of withstanding the effects of transient over-voltage from the ship's network and the effects of DC voltage rise due to regenerated power.

3.8.3.3 Semiconductor convertors are to be protected against overload and short-circuit in accordance with the requirements of 2.5.14.1 of this PART.

3.8.3.4 For liquid-filled semiconductor convertors, consideration is to be given to the provision of an alarm for excessive liquid temperature and of pneumatic protection devices.

3.8.4 Testing

3.8.4.1 Semiconductor convertors are to be tested at the manufacturer in accordance with the requirements of 3.8.4.2 to 3.8.4.5 of this Section. However, the test required in 3.8.4.2 may be omitted for the products produced in series.

3.8.4.2 Semiconductor convertors are to be subjected to temperature rise test under normal working conditions.

3.8.4.3 Semiconductor convertors are to be subjected to functional test.

3.8.4.4 Semiconductor convertors are to withstand a high voltage test at the following testing voltage (with a minimum of 2,000 V):

$$U_p = 2 \times \frac{U_m}{\sqrt{2}} + 1000 \quad \text{V}$$

where: U_p — the effective value of testing voltage, in V;

U_m — the maximum no-load peak value between any pair of terminals of semiconductor convertors. If the voltage to earth is higher than the voltage between two terminals (e.g. the convertors are connected in series), the higher voltage, in V, is to be taken.

If $U_m/\sqrt{2}$ is less than 90 V, U_p is to be taken as 1,000 V.

This testing voltage is to be alternating at any frequency between 25 and 100 Hz and is to be applied between the live parts and any non-current carrying metal part which may be earthed for a period of 1 min without breakdown or flashover.

3.8.4.5 The insulation resistance between live parts of convertors or their accessories and earth is not to be less than 1 MΩ when tested with a DC 500 V megameter.

Section 9 UNINTERRUPTIBLE POWER SYSTEM

3.9.1 Application

3.9.1.1 The UPS① units, to which this Section applies, may provide an alternative power supply or transitional power supply, in lieu of independent accumulator batteries, to services as defined in 2.2.2.1(3) and 2.2.3.1(4) of Chapter 2 of this PART.

3.9.2 Plans and documents

3.9.2.1 The following plans and documents are to be submitted for approval:

(1) General plan;

(2) Electrical schematic diagram;

(3) Technical specifications of the products.

3.9.2.2 The following plans and documents are to be submitted for information:

(1) External wiring diagram;

(2) Specifications of associated electrical appliances;

(3) Operation instructions for the products.

3.9.3 Design and construction

3.9.3.1 UPS units are to be constructed in accordance with IEC 62040, or an acceptable a standard.

3.9.3.2 The operation of the UPS is not to depend upon external services.

3.9.3.3 The type of UPS unit employed, whether off-line, line interactive or on-line, is to be appropriate to the power supply requirements of the connected load equipment.

3.9.3.4 An external bypass is to be provided.

3.9.3.5 The UPS unit is to be monitored and audible and visual alarm is to be given in a normally attended location for:

(1) power supply failure (voltage and frequency) to the connected load;

(2) earth fault;

(3) operation of battery protective device;

(4) when the battery is being discharged; and

(5) when the bypass is in operation for on-line UPS units.

3.9.4 Performance

3.9.4.1 The output power is to be maintained for the duration required for the connected equipment as stated in 2.2.2.1(3) and 2.2.3.1(4) of Chapter 2 of this PART.

3.9.4.2 No additional circuits are to be connected to the UPS unit without verification that the UPS unit has adequate capacity. The UPS battery capacity is, at all times, to be capable of supplying the designated loads for the time specified in Chapter 2 of this PART.

3.9.4.3 On restoration of the input power, the rating of the charge unit is to be sufficient to recharge the batteries while maintaining the output supply to the load equipment.

---

① Refer to IEC publication 62040.

3.9.5 Testing and survey

3.9.5.1 UPS units of 50 kVA and over are to be surveyed by ISC Surveyors during manufacturing and testing.

3.9.5.2 Appropriate testing is to be carried out to demonstrate that the UPS unit is suitable for its intended environment. This is expected to include as a minimum the following tests:

(1) Functionality, including operation of alarms;

(2) Temperature rise;

(3) Ventilation rate;

(4) Battery capacity.

3.9.5.3 Where the supply is to be maintained without a break following a power input failure, this is to be verified after installation by practical test.

Section 10 OTHER ELECTRICAL EQUIPMENT

3.10.1 Incandescent lighting

3.10.1.1 The voltage and load of tungsten filament lamps and lampholders are not to exceed the values specified in Table 3.10.1.1.

Voltage and Load of Tungsten Filament Lamps **Table 3.10.1.1**

Type of lampholders		Voltage (V)	Load
Bayonet cap	B22	250	200W/4A
	B15d	250	250W/4A
	B15s	55	15W/2A
Screw cap	E40	250	3,000W/16A
	E27	250	250W/4A
	E14	250	60W/2A

3.10.1.2 Lampholders are to be constructed of non-toxic, flame-retarding and non-hygroscopic material, and provided with means for locking the lamp in the holder.

3.10.1.3 The temperature rise of terminals for connection of supply cables is not to exceed 40 ℃. Insulation materials of internal parts are to have temperature class corresponding to the maximum temperature within the luminaires.

3.10.2 Tubular fluorescent lamp

3.10.2.1 The voltage and load of the fluorescent lamps and lampholders are not to exceed the values specified in Table 3.10.2.1.

Voltage and Load of Fluorescent Lamps **Table 3.10.2.1**

Type of lampholders	Voltage (V)	Load (W)
G13	250	115
G5	250	80

3.10.2.2 The construction of fluorescent lamp holders is to comply with the requirements of 3.10.1.2 and 3.10.1.3 of this Section.

3.10.3 Discharge lamps operating at voltages above 250 V

3.10.3.1 Discharge lamps must be securely fixed.

3.10.3.2 All independent ballasts, capacitors and other accessories mounted separately from the luminaires are to be enclosed in earthed metal casing.

3.10.3.3 Warning notices calling attention to "DANGER! HIGH VOLTAGE!" are to be provided in accordance with 2.7.1.3 of this PART.

3.10.4 Heating and cooking appliances

3.10.4.1 Heating elements are to be substantially guarded. The holes of the protective guard are to be sufficiently narrow to prevent foreign bodies from falling in.

3.10.4.2 Heating and cooking appliances are to be so constructed that the temperature of supply cable terminals will not exceed the maximum rated conductor temperature given in Table 2.12.2.2 of this PART.

3.10.4.3 Internal connection wires of heating and cooking appliances are to be continuously insulated with incombustible material. Connections between heating elements are not to be effected by soldering.

3.10.4.4 The insulation resistance of heating and cooking appliances in hot condition is not to be less than

0.5 MΩ.

3.10.4.5 Heating and cooking appliances are to be so constructed that the parts which must be hand-held in use cannot be heated to a temperature exceeding the values given in Table 3.10.4.5.

Maximum Temperature of Hand-Held Parts **Table 3.10.4.5**

Material of handles, grips and the like	Maximum temperature for normal hand-held operation (°C)	
	Long period	Short period
Metal	55	60
Porcelain, vitreous material, moulded material, rubber or wood	65	70

3.10.4.6 Heating and cooking appliances and their control gear fitted in galley spaces are to have a degree of protection of at least IP44. Their enclosures are to be corrosion-resistant and provided with one or more drainage holes.

3.10.4.7 Cooking appliances are to be so constructed that spilling or overflowing of liquid or food will not cause insulation failures or short-circuits.

3.10.4.8 Space heaters are to be so constructed, protected and installed that clothing, bedding or other combustible materials cannot come in contact with them in such a manner as to cause risk of fire. Furthermore, they are to be so constructed that combustible materials cannot be placed on the top of their enclosures.

3.10.4.9 Space heaters are to be equipped with means to interrupt the current when the temperature exceeds the permissible limit.

3.10.5 Accessories to luminaires

3.10.5.1 Accessories are to be so designed and constructed that the passages for the insulated conductors are of ample size and free from rough projections, sharp angles, and abrupt bends. All outlets for cables are to have well-rounded edges or be suitably bushed.

3.10.5.2 Accessories are to be so designed and insulated conductors so installed that stress cannot be applied by the conductors to any terminal to which the conductors may be connected.

3.10.5.3 Accessories are to be so designed and fixed that dust and moisture will not readily accumulate on live parts and their insulation.

3.10.5.4 Enclosures are to be made of metal or halogen-free flame-retardant insulating material.

3.10.5.5 When a socket has an earthing pin, the socket and plug are to have additional connections to earth the casing or frame of appliance. When inserting the plug, the earthing pin is to be connected before the live contact pins.

3.10.5.6 Socket outlets of current rating in excess of 16 A are to be interlocked with a switch such that the plug cannot be inserted or withdrawn when the switch is in the “on” position.

3.10.5.7 Socket outlets and plugs with protection degree of IP56 are to be provided with means to maintain the same degree of protection whether the plug is inserted or withdrawn.

3.10.6 LED luminaires for lighting purpose

3.10.6.1 LED luminaires described in this section are used for general lighting purpose only, excluding navigation lights, signal lights and colorful lights for decoration purpose.

3.10.6.2 LED luminaires are to comply with the provisions of IEC Publication 60598-1 Luminaires – Part 1: General requirements and tests and IEC 62722-2-1 Luminaire performance - Part 2-1: Particular requirements for LED luminaires.

CHAPTER 4 SUPPLEMENTARY REQUIREMENTS FOR CARGO SHIPS OF LESS THAN 500 GROSS TONNAGE

Section 1 CARGO SHIPS OF LESS THAN 500 GROSS TONNAGE

4.1.1 General requirements

4.1.1.1 The requirements of this Chapter apply to electrical installations on cargo ships of less than 500 gross tonnage, and may substitute for the related aforesaid requirements in this PART.

4.1.1.2 Except for tankers carrying dangerous liquid cargoes and ships carrying other dangerous goods, an earth indicator may be used instead of an alarm device for monitoring the insulation level to earth as required in 2.4.2.2 of this PART.

4.1.2 Distribution systems

4.1.2.1 In addition to the distribution systems as referred to in 2.4.1.1 of this PART, an AC three-phase four-wire insulated system may be used.

4.1.3 Main source of electrical power

4.1.3.1 The minimum comfortable conditions of habitability as required in 2.1.1.1(2) of this PART may not be complied with.

4.1.3.2 The requirements in 2.1.1.1(4) and (5) of this PART may not be complied with.

4.1.3.3 Distribution boards are not required to be positioned in accordance with 2.1.4.1 of this PART.

4.1.4 Reserve sources of electrical power

4.1.4.1 The emergency source of electrical power as required in Section 2, Chapter 2 of this PART may not be fitted provided that an independent reserve power source in compliance with the following requirements is fitted.

(1) The reserve power source is to be the accumulator battery in compliance with the following requirements:

① located not in the same space as the main source of electrical power and located above the uppermost continuous deck as far as practicable;

② complying with the requirements of 2.2.1.4(1), (2) and 1.2.1.1(2) of this PART;

③ capable of providing immediately power supply for any equipment as required in 4.4.4.1(2) of this Section.

(2) The capacity of the reserve power source is to be sufficient to supply the following equipment for at least 3 h:

① lighting at muster and embarkation stations, over the sides, in all alleyways, stairways and exits, in cabins accommodating more than 16 persons, and at the main switchboard, reserve power source and control stations;

② navigation lights and other signal lights as required in the International Regulations for Preventing Collisions at Sea;

③ internal communication equipment required in emergency;

④ fire detection and fire alarm system (if any);

⑤ daylight signalling lamp in intermittent operation, the ship's whistle, the manually operated call points (if any) and all internal signals that are required in an emergency (e.g. general emergency alarm system, etc.);

⑥ radio communications on board.

4.1.5 Control box for navigation lights

4.1.5.1 The control box of navigation lights may be supplied by the main switchboard and the reserve power source.

4.1.5.2 The alarms for failure required in 2.7.4.4 of this PART may not be satisfied.

4.1.6 Engineers' alarm system

4.1.6.1 Engineers' alarm system required in 2.8.4 of this PART may not be provided.

APPENDIX 1 SHORT-CIRCUIT CURRENTS CALCULATIONS WITH REGARD TO ELECTRICAL INSTALLATIONS

1.1 General Provisions

1.1.1 General requirements

1.1.1.1 This Appendix applies to the calculation of three-phase short-circuit currents that occur on a marine AC electrical installation and short-circuit power factors. The value of a two-phase short-circuit current may be taken as 0.866 times the corresponding value of a three-phase short-circuit current.

1.1.1.2 The calculation methods are for use on unmeshed low and high voltage three-phase alternating current systems operating at 50 Hz or 60 Hz, and having their neutral point connected to the ship's hull through an impedance, or having their neutral point isolated from the ship's hull.

1.1.1.3 The calculating methods described produce sufficiently accurate results to calculate the short-circuit current during the first 100 ms of a fault condition. The results of calculation may be used for:

(1) checking short-circuit making and breaking capacity of the protection devices selected;

(2) checking electrodynamic stability and thermal equilibrium of bus-bars etc.;

(3) providing the basis for design and setting of electrical system protection;

(4) providing the basis for the selection, if necessary, of suitable devices capable of limiting short-circuit currents within the capacity of protective devices.

1.1.1.4 When calculating the maximum short-circuit current, the following are to be considered in the most severe condition, i.e. the condition corresponding to the fully loaded generating plant of ships or offshore installations:

(1) All short-circuit currents fed through generators which may be connected in parallel to the main bus-bar (including the generators transferring load in short time).

(2) All short-circuit currents fed through motors which may be put into service.

1.1.1.5 In general, the short-circuit current is to be calculated at:

(1) output of generators;

(2) main bus-bars;

(3) bus-bars of emergency switchboards, sub-switchboards and distribution boards;

(4) secondary side of power and lighting transformers.

Sometimes, feeder terminal short-circuit currents are additionally to be calculated for design and setting of electrical system protection.

1.1.1.6 The manufacturers are to provide the characteristic parameters of generators, motors, transformers and cables as needed by the calculations and ensure that the parameters are within sufficiently accurate.

1.1.2 Definitions

1.1.2.1 Short-circuit

The accidental or intentional connection, by a relatively low resistance or impedance, of two or more points in a circuit, which are normally at different voltages.

1.1.2.2 Short-circuit current

An over-current resulting from a short circuit due to a fault or an incorrect connection in an electric circuit without any change of the supply.

1.1.2.3 Prospective short-circuit current (with respect to a switching device)

The short-circuit current that would flow in the circuit if each pole of the device were replaced by a conductor of negligible impedance.

1.1.2.4 Symmetrical short-circuit current

The r.m.s. value of the AC symmetrical component of a prospective (available) short-circuit current, the DC component, if any, being neglected.

1.1.2.5 DC component of the short-circuit current

The component of current in the circuit immediately after it has been suddenly short-circuited, all components of fundamentals and harmonics being excluded.

1.1.2.6 Peak short-circuit current

The maximum possible instantaneous value of the prospective (available) short-circuit current.

1.1.2.7 Equivalent generator

In order to calculate short-circuit currents, individual generators and motors in service are combined to form an equivalent generator, the short-circuit current fed through which is equivalent to the sum of the short-circuit currents fed through such generators and motors.

1.1.2.8 Equivalent motor

In order to simplify the calculation of short-circuit currents, individual motors in service, other than large

motors, are combined to form an equivalent motor, the short-circuit current fed through which is equivalent to the sum of the short-circuit currents fed through such motors.

1.1.2.9 Large motor

Any motor rated more than 100 kW or 25% of the rated power of the maximum generator in the system.

1.1.3 Symbols, Subscripts and superscripts

1.1.3.1 General requirements

(1) The symbols, subscripts and superscripts specified in 1.1.3.2 and 1.1.3.3 below are used and uniform units provided in this Appendix.

(2) In case of impedance, reactance, resistance and voltage drops, capital letters denote absolute values and lowercase letters denote relative values (per unit or per cent).

(3) For time-dependent values (current, voltage), capital letters denote r.m.s. values and lowercase letters denote momentary (instantaneous) values.

1.1.3.2 Symbols

(1) Voltage symbols are given in Table 1.1.3.2(1).

Voltage Symbols **Table 1.1.3.2(1)**

Symbol	Name	Unit
E''_{q0}	Subtransient q-axis voltage of a generator	V
E'_{q0}	Transient q-axis voltage of a generator	V
E''_M	Subtransient voltage of a motor	V
U_r	Rated voltage (line to line)	V
U_{rM}	Rated voltage of a motor	V
U_{rT2}	Rated line voltage at the secondary side of a transformer	V
u_K	Rated short circuit voltage of a transformer in %.	%
u_R	Rated ohmic voltage of a transformer in %	%
u_x	Rated ohmic voltage of a transformer in %	%

(2) Current symbols are given in Table 1.1.3.2(2).

Current Symbols **Table 1.1.3.2(2)**

Symbol	Name	Unit
I''_{Kd}, I'_{Kd}	Subtransient and transient short-circuit current of a synchronous generator (r.m.s.)	kA
I''_*, I'_*	Subtransient and transient short-circuit current of an equivalent generator (r.m.s.)	kA
I_*	Current of an equivalent generator (r.m.s.)	kA
I''_M, I''_{M*}	Subtransient short-circuit current of a asynchronous motor and an equivalent motor (r.m.s.)	kA
I_{ac}	Symmetrical short-circuit current at the fault point (r.m.s.)	kA
I_{acG}	Symmetrical short-circuit current of a synchronous generator (r.m.s.)	kA
I_{acM}	Symmetrical short-circuit current of a asynchronous motor (r.m.s)	kA
i_{dc}	DC component of the short-circuit current at the fault point	kA
i_{dcG}	DC component of the short-circuit current of a synchronous generator	kA
i_{dcM}	DC component of the short-circuit current of an asynchronous motor	kA
i_K	Upper envelope of the short-circuit current	kA
I_{K*}	Steady state short-circuit current of an equivalent generator (r.m.s.)	kA
I_{Kd}	Steady state short-circuit current of a synchronous machine (r.m.s.)	kA
i_M	Upper envelope of the short-circuit current of a asynchronous motor	kA
i_{pG}	Peak value of the short-circuit current of a synchronous machine	kA
i_{pM}	Peak value of the short-circuit current of an asynchronous motor	kA
i_p	Peak value of the short-circuit current at the fault point	kA
I_r	Rated current (r.m.s.)	kA
I_{ac2}	Symmetrical short-circuit current at the secondary side of a transformer (r.m.s.)	kA
i_{K2}	Upper envelope of the short-circuit current at the secondary side of a transformer	kA
i_{p2}	Peak value of the short-circuit current at the secondary side of a transformer	kA
I_{CR}	Rated short-circuit breaking capacity of a circuit breaker, as given	kA

Symbol	Name	Unit
I_{Cr}	Rated short-circuit breaking capacity of a circuit breaker, as converted	kA

(3) Symbols of reactance, resistance and impedance are given in Table 1.1.3.2(3).

Symbols of Reactance, Resistance and Impedance **Table 1.1.3.2(3)**

Symbol	Name	Unit
R	Resistance	mΩ
r	Cable resistance per unit length	mΩ/m
R_*	Stator resistance of an equivalent generator	mΩ
R_a	Stator resistance of a synchronous generator	mΩ
R_M	Resistance of an asynchronous motor	mΩ
R_R	Rotor resistance of an asynchronous motor as converted to the stator side	mΩ
R_{R*}	Rotor resistance of an equivalent asynchronous motor as converted to the stator side	mΩ
R_S	Stator resistance of an asynchronous motor	mΩ
R_{S*}	Stator resistance of an equivalent asynchronous motor	mΩ
R_T	Resistance of a transformer	mΩ
X	Reactance	mΩ
x	Cable reactance per unit length	mΩ/m
X''_*, X'_*	Subtransient and transient reactance of an equivalent generator	mΩ
X''_d, X'_d	Subtransient and transient reactance of a synchronous generator in the d-axis	mΩ
X''_M	Subtransient reactance of an asynchronous motor	mΩ
X''_{M*}	Subtransient reactance of an equivalent asynchronous motor	mΩ
X_R	Rotor reactance of an asynchronous motor as converted to the stator side	mΩ
X_S	Stator reactance of an asynchronous motor	mΩ
X_d	Reactance of a synchronous generator in the d-axis	mΩ
X_T	Reactance of a transformer	mΩ
Z	Impedance	mΩ
Z_*	Equivalent impedance	mΩ
Z''_d, Z'_d	Subtransient and transient impedance of a synchronous generator	mΩ
Z''_*, Z'_*	Subtransient and transient impedance of an equivalent generator (including circuit impedance)	mΩ
Z''_M	Subtransient impedance of an asynchronous motor	mΩ
Z''_{M*}	Subtransient impedance of an equivalent asynchronous motor	mΩ
Z_T	Impedance of a transformer	mΩ
R_{e1}	Primary cable resistance of a transformer	mΩ
R_{e2}	Cable resistance at the secondary side of a transformer as converted to the primary side	mΩ
X_{e1}	Primary cable reactance of a transformer	mΩ
X_{e2}	Cable reactance at the secondary side of a transformer as converted to the primary side	mΩ

(4) Symbols of time and time constants are given in Table 1.1.3.2(4).

Symbols of time and time constants **Table 1.1.3.2(4)**

Symbol	Name	Unit
t	Time duration from the beginning of a short circuit	ms
t_x	Defined time duration from the beginning of a short circuit	ms
T''_d, T'_d	Subtransient and transient time constant of a synchronous generator in the d-axis	ms
T''_{d*}, T'_{d*}	Subtransient and transient time constant of an equivalent generator in the d-axis	ms
T''_e, T'_e	Subtransient and transient time constant of a synchronous generator including non-active components	ms
T''_M, T''_{M*}	Subtransient time constant of an asynchronous motor and an equivalent asynchronous motor	ms
T''_{Me}	Subtransient time constant of an asynchronous motor including the connecting cables	ms
T_{dc}, T_{dc*}	DC time constant of a synchronous generator and an equivalent generator	ms

Symbol	Name	Unit
T_{dce}	DC time constant of a synchronous generator including non-active components	ms
T_{dcM}, T_{dcM*}	DC time constant of an asynchronous motor and an equivalent asynchronous motor	ms
T_{dcMe}	DC time constant of an asynchronous motor including the connecting cables	ms

(5) Power symbols are given in Table 1.1.3.2(5).

Power Symbols **Table 1.1.3.2(5)**

Symbol	Name	Unit
S_{rG}	Rated apparent power of a synchronous generator	kVA
P_{rG}	Rated power of a synchronous generator	kW
P_{rM}	Rated output power of an asynchronous motor	kW
P_{rM*}	Rated output power of an equivalent asynchronous motor	kW
S_{rT}	Rated apparent power of a transformer	kVA
P_K	Short circuit losses of a transformer	kW

(6) Other symbols are given in Table 1.1.3.2(6).

Other Symbols **Table 1.1.3.2(6)**

Symbol	Name	Unit
$\cos\varphi_K$	Power factor of a short circuit	
$\cos\varphi_r$	Rated power factor of a generator	
$\cos\varphi_M$	Rated power factor of an asynchronous motor	
η_M	Efficiency of an asynchronous motor	
a	Number of parallel cables	
A_i	Fault point at the power end of a generator breaker	
B_i	Fault point adjacent to the main bus-bar	
C_i	Fault point in the feeder circuit of primary distribution system outside the main bus-bar	
D_i	Fault point at the secondary side of a transformer	
e	Radix of exponential	
f	Frequency	Hz
l	Cable length	m
n	Coefficient of peak value	
S	Sectional area of cable	mm^2
T	Period	ms
CB	Circuit breaker	
FU	Fuse	

1.1.3.3 Subscripts and superscripts

(1) Symbols of subscripts are given in Table 1.1.3.3(1).

Symbols of Subscripts **Table 1.1.3.3(1)**

Symbol	Meaning
*	Equivalent generator and equivalent asynchronous motor
0	Prefault condition
a	**ARMATURE**
ac	**ALTERNATING CURRENT**
d	**DIRECT AXIS**
dc	Direct current
e	Value including non-active components (external)
E, I, U	phasor of E,I and U
G	Synchronous generator
i	Number of generators
j	Number of motors
K	Short circuit
M	Asynchronous motor or group of asynchronous motors
q	Quadrature-axis
R	Rotor of an asynchronous motor

Symbol	Meaning
S	Stator of an asynchronous motor
T	Transformer
Z	Complex impedance

(2) Symbols of superscripts are given in Table 1.1.3.3(2).

1.2 Calculation of Short-circuit Currents

1.2.1 Basic assumptions

1.2.1.1 The formulae described herein, calculate the upper envelope of the maximum value of the time dependent short-circuit current (see Figure 1.2.2.2). The envelope is calculated using particular machine characteristic parameters obtainable from equipment manufacturers using recognized testing methods, and applying the following assumptions:

(1) all system capacitances are neglected;

(2) at the start of the short circuit, the instantaneous value of voltage in one phase at the fault point is zero;

(3) during the short circuit, there is no change in the short-circuit current path;

(4) the short-circuit arc impedance is neglected. The impedance of the bus-bar, potential transformer (PT) and the contact resistance of the connecting points between the conductors are also neglected;

(5) transformers are set at the main tap position;

(6) the short circuit occurs simultaneously in all three phases;

(7) in the prefault condition, the generator is operated at its rated values of load;

(8) for generators connected in parallel, all generators share their active and reactive load proportionally at the start of and during the short circuit;

(9) during each discrete time interval, all circuit components react linearly.

With the above assumptions, the calculation results are considered to be acceptable for the engineering objectives.

1.2.2 Calculation of the short-circuit current fed through a synchronous machine

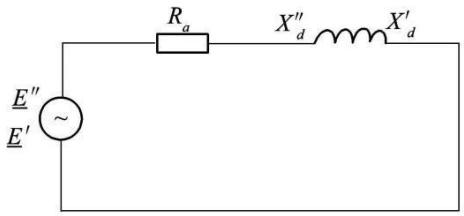
1.2.2.1 General

(1) The synchronous machines used on marine/offshore electrical installations comprise synchronous generators, motors and condensers. The short-circuit currents produced by these machines are fundamental to the calculation of the short-circuit current of an electrical system.

During the first few cycles of a short circuit, all synchronous machines respond in a similar way and accordingly the short-circuit current produced has the same basic characteristics.

(2) Equivalent electrical circuit

When the three-phase terminal short-circuit current of a synchronous generator occurs, the equivalent electrical circuit under subtransient and transient conditions are as shown in Figure 1.2.2.1.



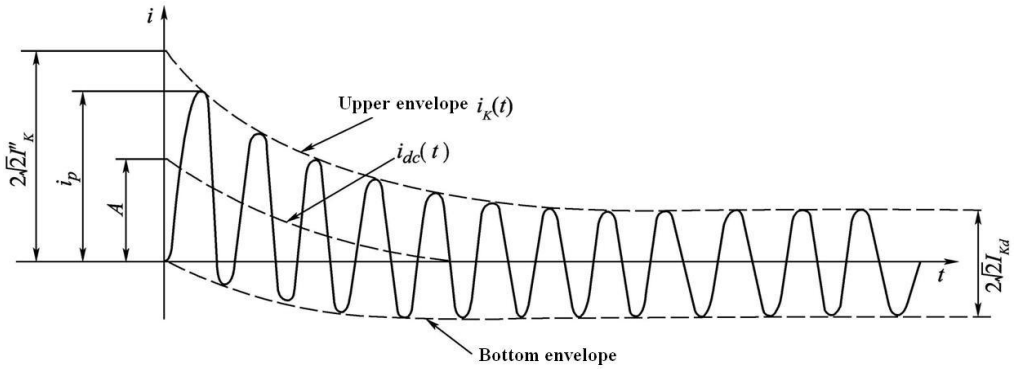


Figure 1.2.2.1 Equivalent Electrical Circuit of the Three-Phase Terminal Short-Circuit Current of a Synchronous Generator

1.2.2.2 Three-phase short-circuit current

(1) The three-phase short-circuit current condition occurs when all three phase are simultaneously shorted together. The resulting current is a complex time-dependent function occurring in each phase. The time-dependent oscillogram of the typical three-phase terminal short-circuit current of a synchronous generator is shown in Figure 1.2.2.2. The current consists of a synchronous short-circuit current (AC components) and DC components.

I''_K – Initial symmetrical short-circuit current; i_p – Peak short-circuit current; I_{Kd} – Steady-state short-circuit current; i_{dc} – Decaying (aperiodic) component of short-circuit current; A – Initial value of the aperiodic component

Figure 1.2.2.2 Terminal Short-Circuit Current Time Function of a Typical Synchronous Generator on No-Load

1.2.2.3 Calculation of the shot-circuit current

(1) When calculating the short-circuit current, it is usual to consider only the highest values of the current, Figure 1.2.2.2 shows that the highest values vary as a function of time along the upper envelope of the complex time-dependent function. The current $i_K(t)$ defined by this upper envelope is calculated from formula (1):

$$i_K(t) = \sqrt{2} I_{ac}(t) + i_{dc}(t) \tag{1}$$

(2) The calculation of symmetrical short-circuit current $I_{ac}(t)$

$I_{ac}(t)$ may be calculated using the following formulae:

$$I_{ac}(t) = (I''_{Kd} - I'_{Kd}) \cdot e^{-t/T''_d} + (I'_{Kd} - I_{Kd}) \cdot e^{-t/T'_d} + I_{Kd} \tag{2}$$

$$I''_{Kd} = \frac{E''_{q0}}{Z''_d} = \frac{E''_{q0}}{\sqrt{R_a{}^2 + X''_d{}^2}} \tag{3}$$

$$I'_{Kd} = \frac{E'_{q0}}{Z'_d} = \frac{E'_{q0}}{\sqrt{R_a{}^2 + X'_d{}^2}} \tag{4}$$

$$E''_{q0} = \sqrt{\left(\frac{U_r}{\sqrt{3}}\cos\varphi_r + R_a \cdot I_r\right)^2 + \left(\frac{U_r}{\sqrt{3}}\sin\varphi_r + X''_d \cdot I_r\right)^2} \tag{5}$$

$$E'_{q0} = \sqrt{\left(\frac{U_r}{\sqrt{3}}\cos\varphi_r + R_a \cdot I_r\right)^2 + \left(\frac{U_r}{\sqrt{3}}\sin\varphi_r + X'_d \cdot I_r\right)^2} \tag{6}$$

(3) I_{Kd} is the steady-state short-circuit current and to be obtained from the manufacturer.

(4) The calculation of the DC component $i_{dc}(t)$

$i_{dc}(t)$ may be calculated from the following formula (7):

$$i_{dc}(t) = \sqrt{2}(I''_{Kd} - I_r \cdot \sin\varphi_r) \cdot e^{-t/T_{dc}} \tag{7}$$

(5) The calculation of the peak value i_p of the short-circuit current

The peak value of the short-circuit current occurs between time $t = 0$ and $t = T/2$ of the short-circuit condition. The exact time depends on the preload conditions, the generator impedance and time constants. In general, it is acceptable to calculate i_p at time $T/2$, i.e. at the first half cycle of the short-circuit condition, using formula (8):

$$i_p = \sqrt{2} I_{ac}\left(\frac{T}{2}\right) + i_{dc}\left(\frac{T}{2}\right) \tag{8}$$

1.2.3 Calculation of the short-circuit current fed through a asynchronous motor

1.2.3.1 General

(1) Quite a number of asynchronous motors are fitted on ships and offshore installations, which can be considered in two broad groups, i.e. large motors and small motors. The grouping depends upon both the system generator capacity and the actual motor rating.

(2) When a short circuit occurs on a system, all motors connected at instant of short circuit, contribute to the short-circuit current. In general large motors must be evaluated individually. Small motors may be grouped together and treated as an equivalent single source.

1.2.3.2 Equivalent electrical circuit

(1) Where the three-phase terminal short-circuit current of an asynchronous motor occurs, the equivalent electrical circuit is as shown in Figure 1.2.3.2.

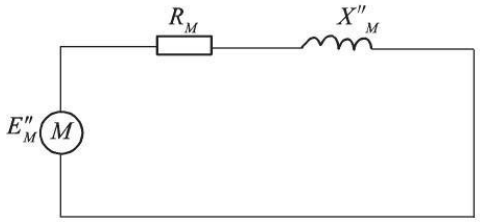

Figure 1.2.3.2 Equivalent Electrical Circuit of the Three-Phase Terminal Short-Circuit Current of an Asynchronous Motor

1.2.3.3 Basic calculation of three-phase short-circuit currents

(1) The upper envelope $i_M(t)$ of the maximum values of the three-phase short-circuit current of an asynchronous motor may be obtained from the following formula:

$$i_M(t) = \sqrt{2} I_{acM}(t) + i_{dcM}(t) \tag{9}$$

(2) The calculation of the symmetrical short-circuit current $I_{acM}(t)$

$I_{acM}(t)$ may be obtained from formula (10):

$$I_{acM}(t) = I''_M \cdot e^{-t/T''_M} \tag{10}$$

If the preload condition is ignored, I''_M may be obtained from the formula (11):

$$I''_M = \frac{U_{rM}}{\sqrt{3} \cdot \sqrt{(R_R + R_S)^2 + (X_R + X_S)^2}} = \frac{U_{rM}}{\sqrt{3} \cdot \sqrt{R_M{}^2 + X''_M{}^2}} \tag{11}$$

(3) Where the of preload condition is ignored, the DC component $i_{dcM}(t)$ and the peak value i_{pM} of the short-circuit may be obtained from formulae (12) and (13) respectively:

$$i_{dcM}(t) = \sqrt{2} I''_M \cdot e^{-t/T_{dcM}} \tag{12}$$

$$i_{pM} = \sqrt{2} I_{acM}(\frac{T}{2}) + i_{dcM}(\frac{T}{2}) \tag{13}$$

1.2.3.4 Calculation of the short-circuit current of large motors

(1) For large motors defined in 1.1.2.9, the terminal short-circuit current is to be calculated using respectively the calculation methods given in 1.2.3.3.

(2) If insufficient motor data are available, the following approximate values for the motor characteristic parameters may be used:

① Motor impedance (for both 50 Hz and 60 Hz installations)

$z''_M = 0.16$

$x''_M = 0.15$

$r_S = 0.034$

$r_R = 0.021$

② Time constants

At 50 Hz, $T''_M = 22.4$ ms, $T_{dcM} = 14.08$ ms

At 60 Hz, $T''_M = 18.67$ ms, $T_{dcM} = 11.73$ ms

1.2.3.5 Calculation of the short-circuit current of small motors

(1) Comparatively speaking, except large motors involved in 1.2.3.4(1), all other motors fitted on ships or offshore installations belong to small motors. The total motor group including their connecting cables may be considered as a single equivalent motor and if insufficient motor data are available, the following approximate values for the motor characteristic parameters may be used:

① Motor impedance (for both 50 Hz and 60 Hz installations)

$z''_M = 0.2$

$x''_M = 0.188$

$r_S = 0.043$

$r_R = 0.027$

② Time constants

At 50 Hz, $T''_M = 22.4$ ms, $T_{dcM} = 14.08$ ms

At 60 Hz, $T''_M = 18.67$ ms, $T_{dcM} = 11.73$ ms

(2) The rated output of the equivalent motor may be calculated in accordance with the Electrical Load Calculations or may be taken as 60% of the total rated active output of actually running generators (excluding those transferring loads in short time) minus the sum of the rated outputs of individual large motors.

1.2.4 Effects of non-active component impedances on short-circuit currents

1.2.4.1 General

(1) In actual electrical systems, the cables, transformers and reactors connected in series with synchronous motors and asynchronous motors are to be also taken into account. Although these components do not feed the short-circuit current, they have a significant impact on the value of the short-circuit current. In general, the net effect is a lower value of short-circuit current which decays more slowly.

1.2.4.2 Effects on short-circuit current of generators

(1) Non-active component impedances R_e and X_e are taken into account by increasing the impedance of the active components, and in formulae (3) and (4) Z''_d and Z'_d are to be replaced by Z''_e and Z'_e where

$$Z''_e = \sqrt{(R_a + R_e)^2 + (X''_d + X_e)^2} \tag{14}$$

$$Z'_e = \sqrt{(R_a + R_e)^2 + (X'_d + X_e)^2} \tag{15}$$

For steady-state short-circuit currents accordingly:

$$Z_e = \sqrt{(R_a + R_e)^2 + (X_d + X_e)^2} \tag{16}$$

However, the effects of the cable impedance on steady-state short-circuit currents between the generator and the main switchboard near the main bus-bar may be ignored.

(2) Time constants T''_d, T'_d and T_{dc} are also changed and become T''_e, T'_e and T_{dce}

$$T''_e = \frac{[(R_a + R_e)^2 + (X''_d + X_e)^2] \cdot X'_d \cdot T''_d}{[(R_a + R_e)^2 + (X''_d + X_e)(X'_d + X_e)] \cdot X''_d} \tag{17}$$

$$T'_e = \frac{[(R_a + R_e)^2 + (X'_d + X_e)^2] \cdot X_d \cdot T'_d}{[(R_a + R_e)^2 + (X'_d + X_e)(X_d + X_e)] \cdot X'_d} \tag{18}$$

$$T_{dce} = \frac{T_{dc} + 1000 X_e / (2\pi f R_a)}{1 + R_e / R_a} \tag{19}$$

1.2.4.3 Effects on short-circuit current of motors

(1) The impedance is increased and in formula (11) R_M and X''_M are to be replaced by R_{Me} and X''_{Me} where

$$R_{Me} = R_R + R_S + R_e \tag{20}$$

$$X'_{Me} = X_R + X_S + X_e \tag{21}$$

(2) Time constant changes

The subtransient time constant:

$$T''_{Me} = \frac{1000 X''_{Me}}{2\pi f R_R} \tag{22}$$

The DC time constant:

$$T''_{dcMe} = \frac{1000 X''_{Me}}{2\pi f (R_s + R_e)} \tag{23}$$

1.2.5 Calculation of short-circuit currents at the main bus-bar

1.2.5.1 General

(1) Owing to neglecting the contact resistance between bus-bars, mutual inductors and conductors, the short circuits within the main bus-bar in the main switchboard are regarded as the short circuit at the main bus-bar.

1.2.5.2 Calculation of the short-circuit current

(1) With the assumption that a ship's electrical system is provided with *i* generators and *j* motors connected in parallel to the main bus-bar, the maximum short-circuit current at the main bus-bar is to be calculated as follows:

① First, the short-circuit current fed through each individual generator and motor is to be calculated in accordance with the requirements of 1.2.2, 1.2.3 and 1.2.4 of this Appendix.

② The maximum short-circuit current at the main bus-bar is to be the algebraic sum of short-circuit currents of individual generators and motors, i.e.:

$$I_{ac}(t) = \sum_i I_{acG}(t)_i + \sum_j I_{acM}(t)_j \tag{24}$$

$$i_{dc}(t) = \sum_i i_{dcG}(t)_i + \sum_j i_{dcM}(t)_j \tag{25}$$

$$i_K(t) = \sum_i i_{KG}(t)_i + \sum_j i_{KM}(t)_j \tag{26}$$

1.2.6 Calculation of the short-circuit current at the feeder circuit outside the main bus-bar

1.2.6.1 Application of the equivalent generator

(1) In order to calculate the short-circuit current at the feeder outside the main bus-bar, all generators and motors, which feed the short-circuit current to fault points, are to be combined to form an equivalent generator at the point of common connection (at the main bus-bar). The short-circuit current fed through the equivalent generator is equal to the sum of the short-circuit currents fed through individual generators and motors.

1.2.6.2 Determination of the characteristic parameters of an equivalent generator

(1) As mentioned above, the short-circuit current fed through the equivalent generator at the main bus-bar is correspondingly equal to the sum of the short-circuit currents fed through individual generators and motors, i.e.:

$$I_{ac}(t)_* = \sum_i I_{acG}(t)_i + \sum_j I_{acM}(t)_j \tag{27}$$

$$i_{dc}(t)_* = \sum_i i_{dcG}(t)_i + \sum_j i_{dcM}(t)_j \tag{28}$$

$$I''_* = \sum_i I''_{Kdei} + \sum_j I''_{Mej} \tag{29}$$

$$I'_* = \sum_i I'_{Kdei} \tag{30}$$

$$I_{K*} = \sum_i I_{Kdei} \tag{31}$$

(2) As in the case of a single generator, the time function $I_{ac}(t)_*$ of the symmetric short-circuit current of the equivalent generator is corresponding to formula (2) as follows:

$$I_{ac}(t)_* = (I''_* - I'_*) \cdot e^{-t/T''_{d*}} + (I'_* - I_{K*}) \cdot e^{-t/T'_{d*}} + I_{K*} \tag{32}$$

Assuming $M_* = I''_* - I'_*$

$N_* = I'_* - I_{K*}$

formula (32) may be rewritten as:

$$I_{ac}(t)_* = M_* \cdot e^{-t/T''_{d*}} + N_* \cdot e^{-t/T'_{d*}} + I_{K*} \tag{33}$$

(3) Determination of equivalent generator subtransient time constant T''_{d*}

Ignoring the transient decay of the short circuit of the generator, the time-dependent function $K''(t)$ of the symmetric short-circuit current for each generator may be expressed as follows:

$$K''(t) = (I''_{Kd} - I'_{Kd}) \cdot e^{-t/T''_d} + I'_{Kd} \tag{34}$$

For the equivalent generator accordingly:

$$K''(t)_* = M_* \cdot e^{-t/T''_{d*}} + I'_* \tag{35}$$

The following is obtained from formulae (27) and (10):

$$K''(t)_* = \sum_i K''(t)_i + \sum_j I''_{Mj} \cdot e^{-t/T''_M} \tag{36}$$

$K''(t_x)_*$ may be obtained using formula (36) where $t = t_x$, then:

$$T''_{d*} = \frac{-t_x}{\ln\left[(K''(t_x)_* - I'_*)/M_*\right]} \tag{37}$$

(4) Determination of equivalent generator transient time constant T'_{d*}

The symmetric short-circuit current fed through the equivalent generator may be calculated using formula (33) where $t = t_x$:

$$I_{ac}(t_x)_* = M_* \cdot e^{-t_x/T''_{d*}} + N_* \cdot e^{-t_x/T'_{d*}} + I_{K*} \tag{38}$$

Similarly, $I_{ac}(t_x)_*$ may be obtained as follows:

$$I_{ac}(t_x)_* = \sum_i I_{acG}(t_x)_i + \sum_j I_{acM}(t_x)_j \tag{39}$$

Accordingly T'_{d*} may be obtained from:

$$T'_{d*} = \frac{-t_x}{\ln\{[I_{ac}(t_x)_* - (M_* \cdot e^{-t_x/T''_{d*}} + I_{K*})]/N_*\}} \tag{40}$$

(5) Determination of DC time constant T_{dc*}

The DC component of the short-circuit current fed through the equivalent generator for $t = t_x$ may be calculated as follows:

$$i_{dc}(t_x)_* = \sqrt{2} I''_* \cdot e^{-t_x/T_{dc*}} \tag{41}$$

and $i_{dc}(t_x)_*$ may be calculated also as follows:

$$i_{dc}(t_x)_* = \sum_i i_{dcG}(t_x)_i + \sum_j i_{dcM}(t_x)_j \tag{42}$$

Accordingly T_{dc*} may be calculated from:

$$T_{dc*} = \frac{-t_x}{\ln[i_{dc}(t_x)_*/(\sqrt{2} I''_*)]} \tag{43}$$

(6) Determination of impedances

Where the preload condition is ignored, the equivalent generator impedance may be obtained as follows:

$$R_* = \frac{1000 X''_*}{2\pi f T_{dc*}} \tag{44}$$

Assuming $C = \frac{1000}{2\pi f T_{dc*}}$,

Hence $R_* = C X''_*$

$$Z''_* = U_r/(\sqrt{3} I''_*) \tag{45}$$

$$Z'_* = U_r/(\sqrt{3} I'_*) \tag{46}$$

$$Z_* = U_r/(\sqrt{3} I_*) \tag{47}$$

Hence:

$$X''_* = \frac{Z''_*}{\sqrt{1 + C^2}} \tag{48}$$

$$X'_* = \sqrt{Z'^2_* - R_*^2} \tag{49}$$

$$X_* = \sqrt{Z_*^2 - R_*^2} \tag{50}$$

1.2.6.3 Calculation of the short-circuit current at the feeder outside the main bus-bar

(1) First, characteristic parameters of an equivalent generator at the main bus-bar are to be obtained in accordance with the above-mentioned requirements of 1.2.6.2. Then the short-circuit current at any point on the feeder outside the main bus-bar may be calculated in accordance with the requirements of 1.2.2 and 1.2.4.

(2) When the short-circuit current at the feeder of a large motor is calculated, the impact of the motor may not be taken into account.

1.2.6.4 Calculation of the short-circuit current at secondary side of transformers

(1) This belongs to one of the cases of the short circuit at the feeder outside the main bus-bar, only the transformer impedance is considered as one part of the circuit impedance (for impedance calculation see 1.4.2), and the changes of the transformer impedance are to be also considered.

1.2.7 Simplified calculation of short-circuit currents

1.2.7.1 Synchronous machines

(1) If the stator resistance is unavailable it may be ignored in formulae (3), (4), (5) and (6). For a short-circuit current calculated at the terminals of a machine, the result will be higher but well within

acceptable tolerances. For system calculations, the error is negligible.
(2) If the preload condition, I_0, is ignored, i.e. assuming a generator on no load in formulae (5), (6), (7) and (8), the values of E''_{q0} and E'_{q0} may be assumed to be equal to $U_r / \sqrt{3}$, and results in lower calculated value (generally less than 10%).
(3) If the transient AC component decay is ignored, formula (2) becomes:

$$I_{ac}(t) = (I''_{Kd} - I'_{Kd}) \cdot e^{-t/T''_d} + I'_{Kd} \tag{51}$$

Excessive inaccuracies occur in the peak short-circuit current for formula (51). Such inaccuracies will invalidate any results calculated beyond the first half-cycle of the fault condition, and accordingly this approximation is not recommended when time-dependent calculations are required.
(4) If the short-circuit current decay is ignored and stator resistance and preload current are ignored for the terminal short-circuit, the AC component of the short-circuit current may be assumed to be a ratio of a constant voltage divided by constant subtransient reactance and the DC component as a proportional constant, i.e.:

$$I_{ac} = U_r / \sqrt{3} X''_d \tag{52}$$

$$i_p = \sqrt{2} I_{ac} + i_{dc} = 1.8(\sqrt{2} I_{ac}) \tag{53}$$

These assumptions are only to be made when estimating approximate values, as the results will produce excessive positive errors for calculations required beyond the first 0.5 cycles.
1.2.7.2 Asynchronous motors
(1) As a first approximation, it may be assumed that all asynchronous motors connected at the time of the short-circuit, contribute an AC short-circuit current equal to their starting current (usually 4 to 7 times the machine's normal full load current).
It may also be assumed that the motor contribution is constant throughout the complete short-circuit fault period.
Such assumptions will give higher values of short-circuit currents than will occur on the actual installation. The error will depend upon the number and size of motors connected.
(2) As above mentioned in 1.2.3.3(2) of this Appendix, if the preload condition is ignored when the short-circuit current of motors is calculated, the preload motor condition can be neglected with negligible errors.
(3) On the basis of asynchronous motor characteristic parameters given in 1.2.3.4(2) and 1.2.3.5(1) of this Appendix, the short-circuit current fed through the motor, with a short circuit occurring near the main bus-bar, may be calculated as follows:

① Large motors:

$I'_M = 6.25 I_{rM}$

$I_{acM} = 4.00 I_{rM}$ (for $t = T/2$)

$i_{pM} = 10 I_{rM}$

② Small motors:

$I''_M = 5 I_{rM}$

$I_{acM} = 3.2 I_{rM}$ (for $t = T/2$)

$i_{pM} = 8 I_{rM}$

(4) If insufficient data is available, the motor rated current may be evaluated using the following formula:

$$I_{rM} = \frac{P_{rM}}{\sqrt{3} \cdot U_{rM} \cdot \eta_M \cdot \cos\varphi_M} \tag{54}$$

where $\eta_M \cdot \cos\varphi_M$ may be calculated from the following formula:

$$\eta_M \cdot \cos\varphi_M = 0.76$$

(5) The short-circuit current of asynchronous motor designed to work in limited service, whose parameters are not completely known, may be calculated assuming the motor is in continuous service and operating at reduced power.

1.3 Calculation of Circuit Power Factor

1.3.1 General

1.3.1.1 The rated short-circuit breaking capacity of the circuit breaker is related to the short-circuit power factor for the interruption of power in the circuit, and the power factor of a short circuit near the main bus-bar on marine and offshore AC electrical installations is generally less than those used for circuit breaker short-circuit tests. Therefore, the short-circuit power factor is to be calculated and if necessary, the short-circuit breaking capacity of the selected breaker is to be converted in accordance with the conversion

coefficient provided by the manufacturer. If insufficient data are available, the method given in Appendix B of this Appendix can be used for conversion (not applicable to the circuit breaker with time delay).

1.3.2 Calculation of short-circuit power factor

1.3.2.1 For the short-circuit at a certain point in way of the feeder outside the main bus-bar, the short-circuit power factor during subtransient periods may be calculated using formula (55):

$$\cos\varphi_K = \frac{R_* + R_e}{\sqrt{(R_* + R_e)^2 + (X''_* + X_e)^2}} \tag{55}$$

1.3.2.2 For the short-circuit near the main bus-bar, the short-circuit power factor during subtransient periods may be calculated in accordance with formula (55), but $R_e = 0$ and $X_e = 0$ are to be taken.

1.4 Calculation and Conversion for Reactance, Resistance and Impedance

1.4.1 Conversion for generator/motor reactance and resistance

(1) Conversion for subtransient reactance acting in the direct axis is as follows:

$$X''_d = x''_d \frac{U_r}{\sqrt{3} I_{rG}} = x''_d \frac{U^2_r}{S_{rG}} \tag{56}$$

(2) Transient reactance acting in the direct axis:

$$X'_d = x'_d \frac{U_r}{\sqrt{3} I_{rG}} = x'_d \frac{U^2_r}{S_{rG}} \tag{57}$$

(3) Conversion for stator resistance:

$$R_a = r_a \frac{U_r}{\sqrt{3} I_{rG}} = r_a \frac{U^2_r}{S_{rG}} \tag{58}$$

1.4.1.1 Conversion for generator reactance and resistance

1.4.1.2 Conversion for motor resistance and reactance

1.4.2 Calculation and conversion for transformer reactance, resistance and impedance

1.4.2.1 Calculation and conversion for transformer reactance and resistance may be carried out using the following formulae:

$$Z_T = u_K \frac{U^2_r}{S_{rT}} \tag{62}$$

$$R_T = P_K \frac{U^2_r}{S^2_{rT}} \tag{63}$$

$$X_T = \sqrt{Z_T^2 - R_T^2} \tag{64}$$

(1) Conversion for mot

$$R_T = r_T \frac{U^2_r}{S_{rT}} = u_R \frac{U_r^2}{S_{rT}} \tag{65}$$

$$X_T = x_T \frac{U^2_r}{S_{rT}} = u_X \frac{U_r^2}{S_{rT}} \tag{66}$$

$$R_s = r_s \frac{U_{rM}}{\sqrt{3} I_{rM}} = r_s \frac{U^2_{rM} \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}} \tag{60}$$

$$R_R = r_R \frac{U_{rM}}{\sqrt{3} I_{rM}} = r_R \frac{U^2_{rM} \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}} \tag{61}$$

1.4.3 Calculation for cable resistance and reactance

1.4.3.1 Cable reactance and resistance can be calculated using the following formulae:

$$R = rl / a \tag{67}$$

$$X = xl / a \tag{68}$$

Appendix A Examples of Calculation

A.1 The diagrammatic sketch of an electrical system

A.1.1 The diagrammatic sketch of an electrical system indicating the position of each fault point is as shown in Figure A.1.1

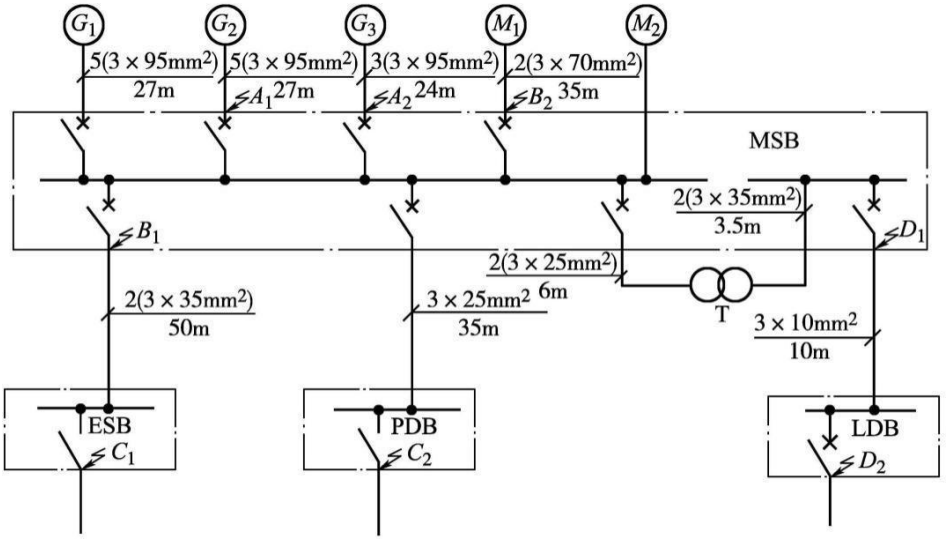

Figure A.1.1 Diagrammatic Sketch of Electrical System

A.2 Parameters for calculation

A.2.1 Generator parameters for calculation are given in Table A.2.1.

Generator Parameters **Table A.2.1**

Code	G_1, G_2	G_3
Type	IFC5502-8TA42	IFC5354-4
S_{rG} (kVA)	550	312.5
U_r (V)	400	400
I_{rG} (kA)	0.79	0.451
f (Hz)	50	50
x''_d	0.112	0.099
x'_d	0.193	0.17
x_d	2.19	3.16
r_a	0.0178	0.0174
T''_d(ms)	3	3
T'_d(ms)	80	49
T_{dc} (ms)	22	20
I_{Kd} (kA)	2.4	1.40

A.2.2 Transformer parameters for calculation are given in Table A.2.2.

Transformer Parameters **Table A.2.2**

Code	T
Type	CSGD-100
S_{rT} (kVA)	100
U_{rT2} (V)	230
u_K (%)	3.5
P_K (kW)	2.0

A.2.3 Motor parameters for calculation are given in Table A.2.3.

Motor Parameters **Table A.2.3**

Code	M_1	M_2 (Equivalent motor)
P_{rM} (kW)	120	408

Code	M_1	M_2 (Equivalent motor)
U_{rM} (V)	380	380
r_R	0.021	0.027
r_S	0.034	0.043
x''_M	0.15	0.188
T''_M (ms)	22.4	22.4
T_{dcM} (ms)	14.076	14.076

A.3 Calculation of the short-circuit current fed through the generator where the short-circuit occurs at the main bus-bar

A.3.1 Calculation of the impedance of cables connecting the generator to the main bus-bar

G_1, G_2:

$$R_e = rl / a = 0.215 \times 27 \div 5 = 1.161 \quad \text{m}\Omega$$

$$X_e = xl / a = 0.0809 \times 27 \div 5 = 0.437 \quad \text{m}\Omega$$

G_3:

$$R_e = rl / a = 0.215 \times 24 \div 3 = 1.72 \quad \text{m}\Omega$$

$$X_e = xl / a = 0.0809 \times 24 \div 3 = 0.647 \quad \text{m}\Omega$$

and resistance

A.3.2 Calculation of generator reactance

G_1, G_2:

$$X''_d = x''_d \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{0.112 \times 160000}{550} = 32.582 \quad \text{m}\Omega$$

$$X'_d = x'_d \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{0.193 \times 160000}{550} = 56.145 \quad \text{m}\Omega$$

$$X_d = x_d \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{2.19 \times 160000}{550} = 637.09 \quad \text{m}\Omega$$

$$R_e = r_a \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{0.0178 \times 160000}{550} = 5.18 \quad \text{m}\Omega$$

G_3:

$$X''_d = x''_d \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{0.099 \times 160000}{312.5} = 50.688 \quad \text{m}\Omega$$

$$X'_d = x'_d \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{0.17 \times 160000}{312.5} = 87.04 \quad \text{m}\Omega$$

$$X_d = x_d \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{3.16 \times 160000}{312.5} = 1617.92 \quad \text{m}\Omega$$

$$R_a = r_a \cdot \frac{U_{rG}^2}{S_{rG}} = \frac{0.0174 \times 160000}{312.5} = 8.909 \quad \text{m}\Omega$$

A.3.3 Calculation of generator phase electromotive forces $\dot{E}''_{q0}$ and $\dot{E}'_{q0}$

G_1, G_2:

$$E''_{q0} = \sqrt{\left(\frac{U_r}{\sqrt{3}}\cos\varphi_r + R_a I_r\right)^2 + \left(\frac{U_r}{\sqrt{3}}\sin\varphi_r + X''_d I_r\right)^2}$$

$$= \sqrt{\left(\frac{400 \times 0.8}{\sqrt{3}} + 5.18 \times 0.79\right)^2 + \left(\frac{400 \times 0.6}{\sqrt{3}} + 32.582 \times 0.79\right)^2}$$

$$= 250.314 \text{ V}$$

$$E'_{q0} = \sqrt{\left(\frac{U_r}{\sqrt{3}}\cos\varphi_r + R_a I_r\right)^2 + \left(\frac{U_r}{\sqrt{3}}\sin\varphi_r + X'_d I_r\right)^2}$$

$$= \sqrt{\left(\frac{400 \times 0.8}{\sqrt{3}} + 5.18 \times 0.79\right)^2 + \left(\frac{400 \times 0.6}{\sqrt{3}} + 56.145 \times 0.79\right)^2}$$

$$= 262.908 \text{ V}$$

G_3:

$$E''_{q0}=\sqrt{(\frac{U_r}{\sqrt{3}}\cos\varphi_r+R_aI_r)^2+(\frac{U_r}{\sqrt{3}}\sin\varphi_r+X''_dI_r)^2}$$
$$=\sqrt{(\frac{400\times0.8}{\sqrt{3}}+8.909\times0.451)^2+(\frac{400\times0.6}{\sqrt{3}}+50.688\times0.451)^2}$$
$$=248.377\ \text{V}$$
$$E'_{q0}=\sqrt{(\frac{U_r}{\sqrt{3}}\cos\varphi_r+R_aI_r)^2+(\frac{U_r}{\sqrt{3}}\sin\varphi_r+X'_dI_r)^2}$$
$$=\sqrt{(\frac{400\times0.8}{\sqrt{3}}+8.909\times0.451)^2+(\frac{400\times0.6}{\sqrt{3}}+87.04\times0.451)^2}$$
$$=259.332\ \text{V}$$

A.3.4 Calculation of generator short-circuit currents

1 Calculations of $I''_{Kde}, I'_{Kde}, T''_e, T'_e$ and T_{dce}

(1) I''_{Kde} and I'_{Kde}

G_1, G_2:

$$I''_{Kde}=\frac{E''_{q0}}{\sqrt{(R_a+R_e)^2+(X''_d+X_e)^2}}$$
$$=\frac{250.314}{\sqrt{(5.18+1.161)^2+(32.582+0.437)^2}}$$
$$=7.445\ \text{kA}$$
$$I'_{Kde}=\frac{E'_{q0}}{\sqrt{(R_a+R_e)^2+(X'_d+X_e)^2}}$$
$$=\frac{262.908}{\sqrt{(5.18+1.161)^2+(56.145+0.437)^2}}$$
$$=4.618\ \text{kA}$$

G_3:

$$I''_{Kde}=\frac{E''_{q0}}{\sqrt{(R_a+R_e)^2+(X''_d+X_e)^2}}$$
$$=\frac{248.377}{\sqrt{(8.909+1.72)^2+(50.688+0.647)^2}}$$
$$=4.738\ \text{kA}$$
$$I'_{Kde}=\frac{E'_{q0}}{\sqrt{(R_a+R_e)^2+(X'_d+X_e)^2}}$$
$$=\frac{259.332}{\sqrt{(8.909+1.72)^2+(87.04+0.647)^2}}$$
$$=2.936\ \text{kA}$$

(2) T''_e, T'_e and T_{dce}

G_1, G_2:

$$T''_e=\frac{[(R_a+R_e)^2+(X''_d+X_e)^2]\cdot X'_d\cdot T''_d}{[(R_a+R_e)^2+(X''_d+X_e)(X'_d+X_e)]\cdot X''_d}$$
$$=\frac{(40.208+1090.254)\times56.145\times3}{(40.208+33.019\times56.582)\times32.582}$$
$$=3.062\quad\text{ms}$$
$$T'_e=\frac{[(R_a+R_e)^2+(X'_d+X_e)^2]\cdot X_d\cdot T'_d}{[(R_a+R_e)^2+(X'_d+X_e)(X_d+X_e)]\cdot X'_d}$$

$$= \frac{(40.208+3201.523)\times 637.09\times 80}{(40.208+56.582\times 637.527)\times 56.145}$$
$$= 81.49 \quad \text{ms}$$

$$T_{dce} = \frac{T_{dc}+1000X_e/(2\pi fR_a)}{1+R_e/R_a}$$
$$= \frac{22+1000\times 0.437/(100\pi\times 5.18)}{1+1.161/5.18}$$
$$= 18.191 \quad \text{ms}$$

G_3:

$$T_e'' = \frac{[(R_a+R_e)^2+(X_d''+X_e)^2]\cdot X_d'\cdot T_d''}{[(R_a+R_e)^2+(X_d''+X_e)(X_d'+X_e)]\cdot X_d''}$$
$$= \frac{(112.9756+2635.282)\times 87.04\times 3}{(112.9756+4501.412)\times 50.688}$$
$$= 3.068 \quad \text{ms}$$

$$T_e' = \frac{[(R_a+R_e)^2+(X_d'+X_e)^2]\cdot X_d\cdot T_d'}{[(R_a+R_e)^2+(X_d'+X_e)(X_d+X_e)]\cdot X_d'}$$
$$= \frac{(112.9756+7689.01)\times 1617.92\times 49}{(112.9756+87.687\times 1618.567)\times 87.04}$$
$$= 50.03 \quad \text{ms}$$

$$T_{dce} = \frac{T_{dc}+1000X_e/(2\pi fR_a)}{1+R_e/R_a}$$
$$= \frac{20+1000\times 0.647/(100\pi\times 8.909)}{1+1.72/8.909}$$
$$= 16.957 \quad \text{ms}$$

2 Where $t = 10$ ms, the short-circuit current is to be calculated as follows:

G_1, G_2:

$$I_{acG} = (I_{Kde}'' - I_{Kde}')\cdot e^{-t/T_e''} + (I_{Kd}' - I_{Kd})\cdot e^{-t/T_e'} + I_{Kd}$$
$$= (7.445-4.618)\cdot e^{-10/3.062} + (4.618-2.4)\cdot e^{-10/81.49} + 2.4$$
$$= 4.47 \text{ kA}$$
$$i_{dcG} = \sqrt{2}(I_{Kde}'' - I_r\cdot\sin\varphi_r)\cdot e^{-t/T_{dce}}$$
$$= \sqrt{2}(7.445-0.79\times 0.6)\cdot e^{-10/18.191}$$
$$= 5.689 \text{ kA}$$
$$i_{pG} = \sqrt{2}I_{acG} + i_{dcG}$$
$$= \sqrt{2}\times 4.47 + 5.689$$
$$= 12.01 \text{ kA}$$

G_3:

$$I_{acG} = (I_{Kde}'' - I_{Kde}')\cdot e^{-t/T_e''} + (I_{Kde}' - I_{Kd})\cdot e^{-t/T_e'} + I_{Kd}$$
$$= (4.738\text{-}2.936)\cdot e^{-10/3.068} + (2.936-1.4)\cdot e^{-10/50.03} + 1.4$$
$$= 2.727 \text{ kA}$$
$$i_{dcG} = \sqrt{2}(I_{Kde}'' - I_r\cdot\sin\varphi_r)\cdot e^{-t/T_{dce}}$$
$$= \sqrt{2}(4.738-0.451\times 0.6)\cdot e^{-10/16.957}$$
$$= 3.503 \text{ kA}$$
$$i_{pG} = \sqrt{2}I_{acG} + i_{dcG}$$
$$= \sqrt{2}\times 2.727 + 3.503$$
$$= 7.36 \text{ kA}$$

A.4 Calculation of the short-circuit current fed through the motor where the short-circuit occurs at the main bus-bar

A.4.1 Calculation of impedance

A.4.1.1 The impedance of large motor M_1

1 Calculation of X''_M, R_S and R_R

$$X''_M = x''_M \frac{U_{rM}{}^2 \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}}$$
$$= \frac{0.15 \times 380^2 \times 0.76}{120}$$
$$= 137.18 \quad \text{m}\Omega$$
$$R_S = r_S \frac{U_{rM}{}^2 \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}}$$
$$= 0.034 \times 914.533$$
$$= 31.094 \quad \text{m}\Omega$$
$$R_R = r_R \frac{U_{rM}{}^2 \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}}$$
$$= 0.021 \times 914.533$$
$$= 19.205 \quad \text{m}\Omega$$

2 Cable impedance from the motor to the main bus-bar

$$R_e = rl / a$$
$$= 0.279 \times 35 \div 2$$
$$= 5.198 \quad \text{m}\Omega$$
$$X_e = xl / a$$
$$= 0.0821 \times 35 \div 2$$
$$= 1.437 \quad \text{m}\Omega$$

A.4.1.2 The impedance of equivalent motor M_2

$$X''_M = x''_M \frac{U_{rM}{}^2 \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}}$$
$$= 0.188 \times \frac{380^2 \times 0.76}{408}$$
$$= 50.568 \quad \text{m}\Omega$$
$$R_S = r_S \frac{U_{rM}{}^2 \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}}$$
$$= 0.043 \times 268.98$$
$$= 11.566 \quad \text{m}\Omega$$
$$R_R = r_R \frac{U_{rM}{}^2 \cdot \eta_M \cdot \cos\varphi_M}{P_{rM}}$$
$$= 0.027 \times 268.98$$
$$= 7.262 \quad \text{m}\Omega$$

A.4.2 Calculation of time constants for large motor M_1

$$T''_{Me} = \frac{1000 X''_{Me}}{2\pi f R_R}$$
$$= \frac{1000(X''_M + X_e)}{2\pi f R_R}$$
$$= \frac{1000 \times (137.18 + 1.437)}{100\pi \times 19.205}$$
$$= 22.975 \quad \text{ms}$$
$$T_{dcMe} = \frac{1000(X''_M + X_e)}{2\pi f (R_s + R_e)}$$
$$= \frac{10 \times 138.617}{\pi \times (31.094 + 5.198)}$$
$$= 12.158 \quad \text{ms}$$

A.4.3 Calculation of short-circuit currents

A.4.3.1 Where t = 10 ms, the short-circuit current of large motor M_1 is to be calculated as follows:

$$I''_{Me} = \frac{U_{rM}}{\sqrt{3}\sqrt{(R_R + R_S + R_e)^2 + (X''_M + X_e)^2}}$$
$$= \frac{380}{\sqrt{3} \times \sqrt{(19.205 + 31.094 + 5.198)^2 + (137.18 + 1.437)^2}}$$
$$= 1.469 \quad \text{kA}$$
$$I_{acM} = I''_{Me} \cdot e^{-t/T''_{Me}}$$
$$= 1.469 \times e^{-10/22.975}$$
$$= 0.951 \quad \text{kA}$$
$$i_{dcM} = \sqrt{2} I''_{Me} \cdot e^{-t/T''_{dcMe}}$$
$$= \sqrt{2} \times 1.469 \times e^{-10/12.158}$$
$$= 0.913 \quad \text{kA}$$
$$i_{pM} = \sqrt{2} I_{acM} + i_{dcM}$$
$$= \sqrt{2} \times 0.951 + 0.913$$
$$= 2.258 \quad \text{kA}$$

A.4.3.2 Where t = 10 ms, the short-circuit current of the equivalent motor (small motor group) M_2 is to be calculated as follows:

$$I''_{Me} = \frac{U_{rM}}{\sqrt{3}\sqrt{(R_S + R_R)^2 + X''^2_M}}$$
$$= \frac{380}{\sqrt{3} \times \sqrt{(11.566 + 7.262)^2 + 50.568^2}}$$
$$= 4.066 \quad \text{kA}$$
$$I_{acM} = I''_{Me} \cdot e^{-t/T''_{Me}}$$
$$= 4.066 \times e^{-10/22.4}$$
$$= 2.602 \quad \text{kA}$$
$$i_{dcM} = \sqrt{2} I''_{Me} \cdot e^{-t/T_{dcMe}}$$
$$= \sqrt{2} \times 4.066 \times e^{-10/14.076}$$
$$= 2.826 \quad \text{kA}$$
$$i_{pM} = \sqrt{2} I_{acM} + i_{dcM}$$
$$= \sqrt{2} \times 2.602 + 2.826$$
$$= 6.506 \quad \text{kA}$$

A.5 Calculation of short-circuit currents at points A_1, A_2, B_1 and B_2

A.5.1 Calculation of the short-circuit current at point A_1

A.5.1.1 Where t = 10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = I_{acG1} + I_{acG3} + I_{acM1} + I_{acM2}$$
$$= 4.47 + 2.727 + 0.951 + 2.602$$
$$= 10.75 \quad \text{kA}$$
$$i_p = i_{pG1} + i_{pG3} + i_{pM1} + i_{pM2}$$
$$= 12.01 + 7.36 + 2.258 + 6.506$$
$$= 28.134 \quad \text{kA}$$

A.5.2 Calculation of the short-circuit current at point A_2

A.5.2.1 Where t = 10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = I_{acG1} + I_{acG2} + I_{acM1} + I_{acM2}$$
$$= 2 \times 4.47 + 0.951 + 2.602$$
$$= 12.493 \quad \text{kA}$$
$$i_p = i_{pG1} + i_{pG2} + i_{pM1} + i_{pM2}$$

$= 2 \times 12.01 + 2.258 + 6.506$
$= 32.784$ kA

A.5.3 Calculation of the short-circuit current at point B_1

A.5.3.1 Where t = 10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = I_{acG1} + I_{acG2} + I_{acG3} + I_{acM1} + I_{acM2}$$
$= 2 \times 4.47 + 2.727 + 0.951 + 2.602$
$= 15.22$ kA

$$i_p = i_{pG1} + i_{pG2} + i_{pG3} + i_{pM1} + i_{pM2}$$
$= 2 \times 12.01 + 7.36 + 2.258 + 6.506$
$= 40.144$ kA

A.5.4 Calculation of the short-circuit current at point B_2

A.5.4.1 Where t = 10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = I_{acG1} + I_{acG2} + I_{acG3} + I_{acM2}$$
$= 2 \times 4.47 + 2.727 + 2.602$
$= 14.269$ kA

$$i_p = i_{pG1} + i_{pG2} + i_{pG3} + i_{pM2}$$
$= 2 \times 12.01 + 7.36 + 6.506$
$= 37.886$ kA

A.6 Calculation of short-circuit currents at points C_1, C_2, D_1 and D_2

A.6.1 Determination of parameters of the equivalent generator where t = 10 ms

A.6.1.1 The determination of subtransient time constant T''_{d*}

1 It may be calculated from formulae (29), (30) and (31):

$$I''_* = \sum_i I''_{Kdei} + \sum_j I''_{Mej}$$
$= 2 \times 7.445 + 4.738 + 1.469 + 4.066$
$= 25.163$ kA

$$I'_* = \sum_i I'_{Kdei}$$
$= 2 \times 4.618 + 2.936$
$= 12.172$ kA

$$I_{K*} = \sum_i I_{Kdi}$$
$= 2 \times 2.4 + 1.4$
$= 6.2$ kA

Hence: $M_* = I''_* - I'_*$
$= 25.163 - 12.172$
$= 12.991$ kA

$N_* = I'_* - I_{K*}$
$= 12.172 - 6.2$
$= 5.972$ kA

2 Where t_x = 10 ms, $K''(t)$ and $K''(t)_*$ of G_1, G_2 and G_3 are to be calculated from formulae (34) and (36)

G_1, G_2:

$$K''(t_x) = (I''_{Kde} - I'_{Kde}) \cdot e^{-t/T''_e} + I'_{Kde}$$
$= (7.445\text{-}4.618) \cdot e^{-10/3.062} + 4.618$
$= 4.726$ kA

G_3:

$$K''(t_x) = (I''_{Kde} - I'_{Kde}) \cdot e^{-t/T''_e} + I'_{Kde}$$
$= (4.738\text{-}2.936) \cdot e^{-10/3.068} + 2.936$
$= 3.005$ kA

Hence: $K''(t_x)_* = \sum_i K''(t_x)_i + \sum_j I''_{Mj} \cdot e^{-t/T''_{Me}}$

$$= 2 \times 4.726 + 3.005 + 0.951 + 2.602$$
$$= 16.01 \quad \text{kA}$$

3 Hence:

$$T''_{d*} = \frac{-t_x}{\ln\left[(K''(t_x)_* - I'_*)/M_*\right]}$$
$$= \frac{-10}{\ln\left[(16.01-12.172)/12.991\right]}$$
$$= 8.20 \quad \text{ms}$$

A.6.1.2 The determination of transient time constant T'

Where t_x = 10 ms, it is to be calculated from formula (39):

$$I_{ac*} = \sum_i I_{acGi} + \sum_j I_{acMj}$$
$$= 15.22 \quad \text{kA (i.e. the value of } I_{ac} \text{ at point } B_1)$$

Hence:

$$T'_{d*} = \frac{-t_x}{\ln\left[\frac{I_{ac}(t_x)_* - (M_* \cdot e^{-t_x/T''_{d*}} + I_{k*})}{N_*}\right]}$$
$$= \frac{-10}{\ln\left[\frac{15.22 - (12.991 \times e^{-10/8.20} + 6.2)}{5.972}\right]}$$
$$= 70.553 \quad \text{ms}$$

A.6.1.3 The determination of DC time constant T_{dc*}

Where t_x = 10 ms, it is to be calculated from formula (42):

$$i_{dc}(t_x)_* = \sum_i i_{dcGi} + \sum_j i_{dcMj}$$
$$= 2 \times 5.689 + 3.503 + 0.913 + 2.826$$
$$= 18.62 \quad \text{kA}$$

Hence:

$$T_{dc*} = \frac{-t_x}{\ln\left[\frac{i_{dc}(t_x)_*}{\sqrt{2}I''_*}\right]}$$
$$= \frac{-10}{\ln\left[\frac{18.62}{\sqrt{2} \times 25.163}\right]}$$
$$= 15.439 \quad \text{ms}$$

A.6.1.4 The determination of impedance

It may be calculated from formulae (45), (46) and (47):

$$Z''_* = \frac{U_r}{\sqrt{3}I''_*} = \frac{400}{\sqrt{3} \times 25.163} = 9.178 \quad \text{m}\Omega$$

$$Z'_* = \frac{U_r}{\sqrt{3}I'_*} = \frac{400}{\sqrt{3} \times 12.172} = 18.973 \quad \text{m}\Omega$$

$$Z_* = \frac{U_r}{\sqrt{3}I_{K*}} = \frac{400}{\sqrt{3} \times 6.2} = 37.248 \quad \text{m}\Omega$$

and

$$C = \frac{1000}{2\pi f T_{dc*}} = \frac{10}{\pi \times 15.439} = 0.2062 \quad \text{m}\Omega$$

Hence:

$$X''_* = \frac{Z''_*}{\sqrt{1+C^2}} = \frac{9.178}{\sqrt{1+0.2062^2}} = 8.99 \quad \text{m}\Omega$$

$$R_* = CX''_* = 0.2062 \times 8.99 = 1.854 \quad \text{m}\Omega$$

$$X'_* = \sqrt{Z'^2_* - R_*^2} = \sqrt{18.973^2 - 1.854^2} = 18.88 \quad \text{m}\Omega$$

$$X_* = \sqrt{Z_*^2 - R_*^2} = \sqrt{37.248^2 - 1.854^2} = 37.202 \quad \text{m}\Omega$$

A.6.2 Calculation of the short-circuit current at point C_1

A.6.2.1 The calculation of the circuit impedance from the main bus-bar to fault points

$$R_e = rl/a = 0.582 \times 50/2 = 14.55 \quad \text{m}\Omega$$

$$X_e = xl/a = 0.0871 \times 50/2 = 2.178 \quad \text{m}\Omega$$

A.6.2.2 The calculation of $T_e^{''}, T_e^{'}$ and T_{dce}

$$T_e'' = \frac{[(R_* + R_e)^2 + (X_*'' + X_e)^2] \cdot X_*' \cdot T_{d*}''}{[(R_* + R_e)^2 + (X_*'' + X_e)(X_*' + X_e)] \cdot X_*''}$$

$$= \frac{[(1.854+14.55)^2 + (8.99+2.178)^2] \times 18.88 \times 8.20}{[(1.854+14.55)^2 + (8.99+2.178)(18.88+2.178)] \times 8.99}$$

$$= 13.449 \quad \text{ms}$$

$$T_e' = \frac{[(R_* + R_e)^2 + (X_*' + X_e)^2] \cdot X_* \cdot T_{d*}'}{[(R_* + R_e)^2 + (X_*' + X_e)(X_* + X_e)] \cdot X_*'}$$

$$= \frac{[(1.854+14.55)^2 + (18.88+2.178)^2] \times 37.202 \times 70.553}{[(1.854+14.55)^2 + (18.88+2.178)(37.202+2.178)] \times 18.88}$$

$$= 90.186 \quad \text{ms}$$

$$T_{dce} = \frac{T_{dc*} + 1000 X_e / (2\pi f R_*)}{1 + R_e / R_*}$$

$$= \frac{15.439 + 1000 \times 2.178 / (100\pi \times 1.854)}{1 + 14.55/1.854}$$

$$= 2.168 \quad \text{ms}$$

A.6.2.3 The calculation of $I_{Kde}^{''}$, $I_{Kde}^{'}$ and I_{Kde}

$$I_{Kde}^{''} = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_*^{''} + X_e)^2}}$$

$$= \frac{400/\sqrt{3}}{\sqrt{(1.854+14.55)^2 + (8.99+2.178)^2}}$$

$$= 11.637 \quad \text{kA}$$

$$I_{Kde}^{'} = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_*^{'} + X_e)^2}}$$

$$= \frac{400/\sqrt{3}}{\sqrt{(1.854+14.55)^2 + (18.88+2.178)^2}}$$

$$= 8.652 \quad \text{kA}$$

$$I_{Kde} = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_* + X_e)^2}}$$

$$= \frac{400/\sqrt{3}}{\sqrt{(1.854+14.55)^2 + (37.202+2.178)^2}}$$

$$= 5.413 \quad \text{kA}$$

A.6.2.4 Where t = 10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = (I_{Kde}^{''} - I_{Kde}^{'}) \cdot e^{-t/T_e^{''}} + (I_{Kde}^{'} - I_{Kde}) \cdot e^{-t/T_e^{'}} + I_{Kde}$$

$$= (11.637 - 8.652) \cdot e^{-10/13.449} + (8.652 - 5.413) \cdot e^{-10/90.186} + 5.413$$

$$= 9.731 \quad \text{kA}$$

$$i_{dc} = \sqrt{2} I_{Kde}^{''} \cdot e^{-t/T_{dce}}$$

$$= \sqrt{2} \times 11.637 \times e^{-10/2.168}$$

$$= 0.163 \quad \text{kA}$$

$$i_p = \sqrt{2} I_{ac} + i_{dc}$$
$$= \sqrt{2} \times 9.731 + 0.163$$
$$= 13.925 \quad \text{kA}$$

A.6.3 Calculation of the short-circuit current and power factor at point C_2

A.6.3.1 The calculation of the circuit impedance from the main bus-bar to fault points

$$R_e = rl / a = 0.807 \times 35 = 28.245 \quad \text{m}\Omega$$
$$X_e = xl / a = 0.0855 \times 35 = 3.098 \quad \text{m}\Omega$$

A.6.3.2 The calculation of T'', T' and T

$$T_e'' = \frac{[(R_* + R_e)^2 + (X_*'' + X_e)^2] \cdot X_*' \cdot T_{d*}''}{[(R_* + R_e)^2 + (X_*'' + X_e)(X_*' + X_e)] \cdot X_*''}$$
$$= \frac{[(1.854 + 28.245)^2 + (8.99 + 3.098)^2] \times 18.88 \times 8.20}{[(1.854 + 28.245)^2 + (8.99 + 3.098)(18.88 + 3.098)] \times 8.99}$$
$$= 15.464 \quad \text{ms}$$
$$T_e' = \frac{[(R_* + R_e)^2 + (X_*' + X_e)^2] \cdot X_* \cdot T_{d*}'}{[(R_* + R_e)^2 + (X_*' + X_e)(X_* + X_e)] \cdot X_*'}$$
$$= \frac{[(1.854 + 28.245)^2 + (18.88 + 3.098)^2] \times 37.202 \times 70.553}{[(1.854 + 28.245)^2 + (18.88 + 3.098)(37.202 + 3.098)] \times 18.88}$$
$$= 107.775 \quad \text{ms}$$
$$T_{dce} = \frac{T_{dc*} + 1000 X_e / (2\pi f R_*)}{1 + R_e / R_*}$$
$$= \frac{15.439 + 1000 \times 3.098 / (100\pi \times 1.854)}{1 + 28.245 / 1.854}$$
$$= 1.28 \quad \text{ms}$$

A.6.3.3 The calculation of I''_{Kde}, I'_{Kde} and I^{dce}_{Kde}

$$I''_{Kde} = \frac{U_r / \sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_*'' + X_e)^2}}$$
$$= \frac{400 / \sqrt{3}}{\sqrt{(1.854 + 28.245)^2 + (8.99 + 3.098)^2}}$$
$$= 7.12 \quad \text{kA}$$
$$I'_{Kde} = \frac{U_r / \sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_*' + X_e)^2}}$$
$$= \frac{400 / \sqrt{3}}{\sqrt{(1.854 + 28.245)^2 + (18.88 + 3.098)^2}}$$
$$= 6.197 \quad \text{kA}$$
$$I_{Kde} = \frac{U_r / \sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_* + X_e)^2}}$$
$$= \frac{400 / \sqrt{3}}{\sqrt{(1.854 + 28.245)^2 + (37.202 + 3.098)^2}}$$
$$= 4.591 \quad \text{kA}$$

A.6.3.4 Where: t = 10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = (I''_{Kde} - I'_{Kde}) \cdot e^{-t/T_e''} + (I'_{Kde} - I_{Kde}) \cdot e^{-t/T_e'} + I_{Kde}$$
$$= (7.12 - 6.197) \cdot e^{-10/15.464} + (6.197 - 4.591) \cdot e^{-10/107.775} + 4.591$$
$$= 6.538 \quad \text{kA}$$
$$i_{dc} = \sqrt{2} I''_{Kde} \cdot e^{-t/T_{dce}}$$

$$= \sqrt{2} \times 7.12 \times e^{-10/1.28}$$
$$= 0.0041 \quad \text{kA}$$
$$i_p = \sqrt{2} I_{ac} + i_{dc}$$
$$= \sqrt{2} \times 6.538 + 0.0041$$
$$= 9.25 \quad \text{kA}$$

A.6.4 Calculation of the short-circuit current at point D_1

A.6.4.1 The calculation of the circuit impedance from the main bus-bar to fault points

1. The primary circuit impedance of a transformer

$$R_{e1} = rl / a = 0.807 \times 6 / 2 = 2.421 \quad \text{mΩ}$$
$$X_{e1} = xl / a = 0.0885 \times 6 / 2 = 0.2655 \quad \text{Mω}$$

2. The calculation of the transformer impedance

$$Z_T = u_K \cdot \frac{U_r^{\ 2}}{S_{rT}}$$
$$= 3.5\% \times \frac{400^2}{100}$$
$$= 56 \quad \text{mΩ}$$
$$R_T = P_K \cdot \frac{U_r^{\ 2}}{S_{rT}^{\ 2}}$$
$$= 2.0 \times \frac{400^2}{100^2}$$
$$= 32 \quad \text{mΩ}$$
$$X_T = \sqrt{Z_T^{\ 2} - R_T^{\ 2}}$$
$$= \sqrt{56^2 - 32^2}$$
$$= 45.9565 \quad \text{mΩ}$$

3. The circuit impedance at the secondary side of the transformer as converted to the primary side

$$R_{e2} = (rl / a) \cdot (U_r / U_{rT2})^2$$
$$= (0.582 \times 3.5 / 2) \times (400 / 230)^2$$
$$= 3.0805 \quad \text{mΩ}$$
$$X_{e2} = (xl / a) \cdot (U_r / U_{rT2})^2$$
$$= (0.0871 \times 3.5/2) \times (400/230)^2$$
$$= 0.461 \quad \text{mΩ}$$

4. The circuit impedance from the main bus-bar to fault points

$$R_e = R_{e1} + R_T + R_{e2}$$
$$= 2.421 + 32 + 3.0805$$
$$= 37.5015 \quad \text{mΩ}$$
$$X_e = X_{e1} + X_T + X_{e2}$$
$$= 0.2655 + 45.9565 + 0.461$$
$$= 46.683 \quad \text{mΩ}$$

A.6.4.2 The calculation of T_e'', T_e' and T_{dce}

$$T_e'' = \frac{[(R_* + R_e)^2 + (X_*'' + X_e)^2] \cdot X_*' \cdot T_{d*}''}{[(R_* + R_e)^2 + (X_*'' + X_e)(X_*' + X_e)] \cdot X_*''}$$
$$= \frac{[(1.854 + 37.5015)^2 + (8.99 + 46.683)^2] \times 18.88 \times 8.20}{[(1.854 + 37.5015)^2 + (8.99 + 46.683)(18.88 + 46.683)] \times 8.99}$$
$$= 15.397 \quad \text{ms}$$
$$T_e' = \frac{[(R_* + R_e)^2 + (X_*' + X_e)^2] \cdot X_* \cdot T_{d*}'}{[(R_* + R_e)^2 + (X_*' + X_e)(X_* + X_e)] \cdot X_*'}$$
$$= \frac{[(1.854 + 37.5015)^2 + (18.88 + 46.683)^2] \times 37.202 \times 70.553}{[(1.854 + 37.5015)^2 + (18.88 + 46.683)(37.202 + 46.683)] \times 18.88}$$

$$= 115.328 \quad \text{ms}$$

$$T_{dce} = \frac{T_{dc*} + 1000X_e/(2\pi f R_*)}{1 + R_e/R_*}$$

$$= \frac{15.439 + 1000 \times 46.683/(100\pi \times 1.854)}{1 + 37.5015/1.854}$$

$$= 4.503 \quad \text{ms}$$

A.6.4.3 The calculation of I''_{Kde}, I'_{Kde} and I_{Kde}

$$I''_{Kde} = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X''_* + X_e)^2}}$$

$$= \frac{400/\sqrt{3}}{\sqrt{(1.854 + 37.5015)^2 + (8.99 + 46.683)^2}}$$

$$= 3.387 \quad \text{kA}$$

$$I'_{Kde} = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X'_* + X_e)^2}}$$

$$= \frac{400/\sqrt{3}}{\sqrt{(1.854 + 37.5015)^2 + (18.88 + 46.683)^2}}$$

$$= 3.02 \quad \text{kA}$$

$$I_{Kde} = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_* + X_e)^2}}$$

$$= \frac{400/\sqrt{3}}{\sqrt{(1.854 + 37.5015)^2 + (37.202 + 46.683)^2}}$$

$$= 2.492 \quad \text{kA}$$

A.6.4.4 Where t = 10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = (I''_{Kde} - I'_{Kde}) \cdot e^{-t/T''_e} + (I'_{Kde} - I_{Kde}) \cdot e^{-t/T'_e} + I_{Kde}$$

$$= (3.387 - 3.02) \cdot e^{-10/15.397} + (3.02 - 2.492) \cdot e^{-10/115.328} + 2.492$$

$$= 3.168 \quad \text{kA}$$

$$i_{dc} = \sqrt{2} I''_{Kde} \cdot e^{-t/T_{dce}}$$

$$= \sqrt{2} \times 3.387 \times e^{-10/4.503}$$

$$= 0.52 \quad \text{kA}$$

$$i_p = \sqrt{2} I_{ac} + i_{dc}$$

$$= \sqrt{2} \times 3.168 + 0.52$$

$$= 5.0 \quad \text{kA}$$

The short-circuit current at the secondary side of a transformer

$$I_{ac2} = I_{ac}(U_r/U_{rT2})$$

$$= 3.168 \times 400/230$$

$$= 5.51 \text{ kA}$$

$$i_{p2} = i_p(U_r/U_{rT2})$$

$$= 5.0 \times 400/230$$

$$= 8.696 \quad \text{kA}$$

A.6.5 Calculation of the short-circuit current at point D_2

A.6.5.1 The calculation of the circuit impedance from the main bus-bar to fault points

1 The circuit impedance from the main bus-bar to the lighting bus-bar (i.e. the impedance at point D_1)

$R_e = 37.5015$ mΩ

$X_e = 46.683$ mΩ

2 The circuit impedance from the lighting bus-bar to fault points as converted to the primary side of the transformer

$$R_{e2} = (rl/a)\cdot(U_r/U_{rT2})^2$$
$$= (2.02 \times 10/1)\times(400/230)^2$$
$$= 61.096 \quad \text{m}\Omega$$
$$X_{e2} = (xl/a)\cdot(U_r/U_{rT2})^2$$
$$= (0.0957\times 10/1)\times(400/230)^2$$
$$= 2.895 \quad \text{m}\Omega$$

3 The circuit impedance from the main bus-bar to fault points

$$R_e = R_{e(D1)} + R_{e2}$$
$$= 37.5015 + 61.096$$
$$= 98.598 \quad \text{m}\Omega$$
$$X_e = X_{e(D1)} + X_{e2}$$
$$= 46.683 + 2.895$$
$$= 49.578 \quad \text{m}\Omega$$

A.6.5.2 The calculation of T_e'', T_e' and T_{dce}

$$T_e'' = \frac{[(R_* + R_e)^2 + (X_*'' + X_e)^2]\cdot X_*'\cdot T_{d*}''}{[(R_* + R_e)^2 + (X_*'' + X_e)(X_*' + X_e)]\cdot X_*''}$$
$$= \frac{[(1.854 + 98.598)^2 + (8.99 + 49.578)^2]\times 18.88\times 8.20}{[(1.854 + 98.598)^2 + (8.99 + 49.578)(18.88 + 49.578)]\times 8.99}$$
$$= 16.513 \quad \text{ms}$$
$$T_e' = \frac{[(R_* + R_e)^2 + (X_*' + X_e)^2]\cdot X_*\cdot T_{d*}'}{[(R_* + R_e)^2 + (X_*' + X_e)(X_* + X_e)]\cdot X_*'}$$
$$= \frac{[(1.854 + 98.598)^2 + (18.88 + 49.578)^2]\times 37.202\times 70.553}{[(1.854 + 98.598)^2 + (18.88 + 49.578)(37.202 + 49.578)]\times 18.88}$$
$$= 128.144 \quad \text{ms}$$
$$T_{dce} = \frac{T_{dc*} + 1000X_e/(2\pi f R_*)}{1 + R_e/R_*}$$
$$= \frac{15.439 + 1000\times 49.578/(100\pi\times 1.854)}{1 + 98.598/1.854}$$
$$= 1.89 \quad \text{ms}$$

A.6.5.3 The calculation of I_{Kde}'', I_{Kde}' and I_{Kde}

$$I_{Kde}'' = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_*'' + X_e)^2}}$$
$$= \frac{400/\sqrt{3}}{\sqrt{(1.854 + 98.598)^2 + (8.99 + 49.578)^2}}$$
$$= 1.986 \quad \text{kA}$$
$$I_{Kde}' = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_*' + X_e)^2}}$$
$$= \frac{400/\sqrt{3}}{\sqrt{(1.854 + 98.598)^2 + (18.88 + 49.578)^2}}$$
$$= 1.899 \quad \text{kA}$$
$$I_{Kde} = \frac{U_r/\sqrt{3}}{\sqrt{(R_* + R_e)^2 + (X_* + X_e)^2}}$$
$$= \frac{400/\sqrt{3}}{\sqrt{(1.854 + 98.598)^2 + (37.202 + 49.578)^2}}$$
$$= 1.74 \quad \text{kA}$$

A.6.5.4 Where t =10 ms, the short-circuit current is to be calculated as follows:

$$I_{ac} = (I''_{Kde} - I'_{Kde}) \cdot e^{-t/T''_e} + (I'_{Kde} - I_{Kde}) \cdot e^{-t/T'_e} + I_{Kde}$$
$$= (1.986 - 1.899) \cdot e^{-10/16.513} + (1.899 - 1.74) \cdot e^{-10/128.144} + 1.74$$
$$= 1.931 \quad \text{kA}$$
$$i_{dc} = \sqrt{2} I''_{Kde} \cdot e^{-t/T_{dce}}$$
$$= \sqrt{2} \times 1.986 \times e^{-10/1.89}$$
$$= 0.0141 \quad \text{kA}$$
$$i_p = \sqrt{2} I_{ac} + i_{dc}$$
$$= \sqrt{2} \times 1.931 + 0.0141$$
$$= 2.745 \quad \text{kA}$$

The short-circuit current at the secondary side of a transformer

$$I_{ac2} = I_{ac}(U_r / U_{rT2})$$
$$= 1.931 \times 400/230$$
$$= 3.358 \quad \text{kA}$$
$$i_{p2} = i_p(U_r / U_{rT2})$$
$$= 2.745 \times 400/230$$
$$= 4.774 \quad \text{kA}$$

A.7 Calculation of short-circuit power factors

A.7.1 Calculation of short-circuit power factors at points A_1, A_2, B_1 and B_2.

$$\cos\varphi_K = \frac{R_*}{\sqrt{R_*^2 + X_*''^2}}$$
$$= \frac{1.854}{\sqrt{1.854^2 + 8.99^2}}$$
$$= 0.202$$

A.7.2 Calculation of short-circuit power factors at points C_1, C_2, D_1 and D_2

1 At point C_1:

$$\cos\varphi_K = \frac{R_* + R_e}{\sqrt{(R_* + R_e)^2 + (X''_* + X_e)^2}}$$
$$= \frac{1.854 + 14.55}{\sqrt{(1.854 + 14.55)^2 + (8.99 + 2.178)^2}}$$
$$= 0.827$$

2 At point C_2:

$$\cos\varphi_K = \frac{R_* + R_e}{\sqrt{(R_* + R_e)^2 + (X''_* + X_e)^2}}$$
$$= \frac{1.854 + 28.245}{\sqrt{(1.854 + 28.245)^2 + (8.99 + 3.098)^2}}$$
$$= 0.928$$

3 At point D_1:

$$\cos\varphi_K = \frac{R_* + R_e}{\sqrt{(R_* + R_e)^2 + (X''_* + X_e)^2}}$$
$$= \frac{1.854 + 37.5015}{\sqrt{(1.854 + 37.5015)^2 + (8.99 + 46.683)^2}}$$
$$= 0.577$$

4 At point D_2:

$$\cos\varphi_K = \frac{R_* + R_e}{\sqrt{(R_* + R_e)^2 + (X''_* + X_e)^2}}$$

$$= \frac{1.854 + 98.598}{\sqrt{(1.854 + 98.598)^2 + (8.99 + 49.578)^2}}$$
$$= 0.864$$

A.8 A complete summary of results of short-circuit current calculation and data of selected protective devices

A.8.1 A complete summary of the results of the short-circuit current calculation and the data of the selected protective devices is given in Table A.8.1.

A Complete Summary of Results of Short-Circuit Current Calculation and Data of Selected Protective Devices **Table A.8.1**

Results of short-circuit current calculation					Selected protective devices								
Code of fault points	Time after occurrence of short-circuit	Symmetrical short-circuit current (kA)	Upper envelope of short-circuit current (kA)	Power factor of short-circuit current	Type	Rated current (A)	Rated voltage (V)	Rated short-circuit breaking capacity (kA)	Rated short-circuit making capacity (kA)	Rated short-time withstanding current (kA)	Power factor of short-circuit	$\cos\varphi_K$ conversion

Notes:

① High-efficiency instantaneous trip breaker for the primary side of transformer T, with the transient current being 4 kA.

② Circuit breaker for feeders connecting main switchboard and emergency switch board.

③ Points D_1 and D_2 are short-circuit currents at the secondary side of the transformer.

Appendix B Conversion of Short-Circuit Breaking Capacity of Circuit Breaker

B.1 Foreword

The rated short-circuit breaking capacity of a circuit breaker is values provided by the manufacturer for the short-circuit breaking capacity corresponding to different rated operational voltages at the rated frequency and specified short-circuit power factor.

Because the sources of the short-circuit current in marine AC electrical systems are AC synchronous and asynchronous motors and the short-circuit power factor is small, the short-circuit power factors specified in standards for industrial circuit breakers cannot in general meet marine requirements.

This Appendix provides a method for conversion of the short-circuit breaking capacity where the given value of the test power factor of the selected breaker is not in compliance with the actual short-circuit power factor required for a marine electrical system.

B.2 Conversion method

The conversion is to be in accordance with the following steps:

a. The peak coefficient n corresponding to the given value of the test short-circuit power factor $\cos\varphi_{Kr}$ of the breaker may be obtained from Figure B.2.

Note: Where only the rated short-circuit making capacity and rated short-circuit breaking capacity of the breaker is given, the ratio of the rated short-circuit making capacity to the rated short-circuit breaking capacity is peak coefficient n.

b. The peak coefficient n' corresponding to the actually required short-circuit power factor $\cos\varphi_K$ may be obtained from Figure B.2.

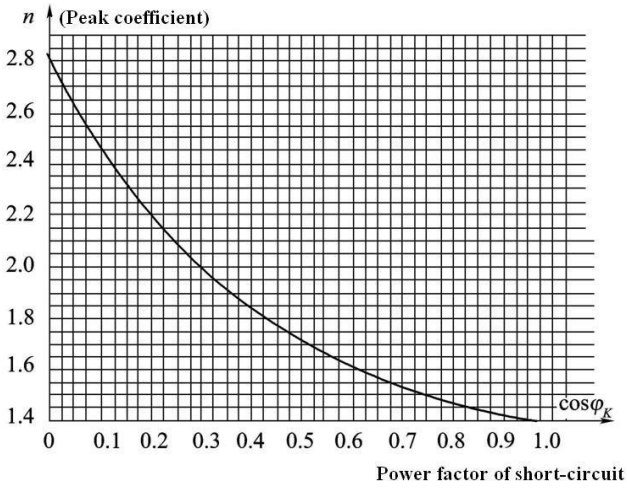

Figure B.2 Curve where Peak Value Coefficient $n = f(\cos\varphi_K)$

c. With the short-circuit power factor $\cos\varphi_K$, the short-circuit breaking capacity I_{Cr} of the breaker conversion is as follows:

$$I_{Cr} = \frac{n}{n'} I_{CR} = CI_{CR}$$

B.3 Example

It is assumed that the considered short-circuit power factor $\cos\varphi_K$ at the main bus-bar of a ship equals 0.16, and the known parameters of the selected TO-100BA circuit breaker are as follows:

Rated voltage: 500 V

Rated short-circuit breaking capacity: 18 kA

Rated short-circuit making capacity: 38 kA

Evaluation: The value of the short-circuit breaking capacity where the short-circuit power factor $\cos\varphi_K = 0.16$.

Solution:

(a) $n = \frac{38}{18} = 2.111$;

(b) $n' = 2.30$ where $\cos\varphi_K = 0.16$, as shown in Figure B.2;

(c) $I_{Cr} = \frac{n}{n'} I_{CR} = \frac{2.111}{2.30} \times 18 = 16.52$ kA.

APPENDIX 2 TYPE APPROVAL PROCEDURE FOR CABLE TRAYS/PROTECTIVE CASINGS MADE OF PLASTIC MATERIALS

1.1 General design requirements

1.1.1 Ambient temperatures

Cable trays/protective casings are to be designed to the following ambient temperatures:

–25℃ to 90℃ for outdoor use;

+ 5℃ to 90℃ for indoor use.

Consideration will be given to the use of plastic cable trays/protective casings in the cold environment where the ambient temperature is below –25℃ provided the mechanical properties of the plastics can be maintained for the intended purpose and the installation location. In this particular instance, the cold bend and cold impact properties of the material are also to be considered.

1.1.2 Safe Working Load

Cable trays/protective casings are to be assigned a Safe Working Load in accordance with 2.2.2 of this Appendix.

1.2 Mechanical requirements

1.2.1 Impact resistance test

The test is to be performed according to IEC 60068-2-75 using the pendulum hammer.

1.2.1.1 The test is to be carried out on samples of cable tray lengths or cable ladder lengths, of 250 mm ±5 mm long. Samples of ladder are to consist of two side-members with one rung positioned centrally. Samples of mesh trays are to be prepared in such a way that there will be a wire in the centre.

1.2.1.2 Before the test, plastic components are to be aged at a temperature of 90℃ ±2℃ for 240 h continuously.

1.2.1.3 The samples are to be mounted on wooden fibreboard of thickness 20 mm ±2 mm.

1.2.1.4 The samples to be tested are to be placed in a refrigerator, the temperature within which is maintained at the declared temperature according to 1.1 above with a tolerance of ±2℃.

1.2.1.5 After 2 h, the samples are, in turn, to be removed from the refrigerator and immediately placed in the test apparatus.

1.2.1.6 At 10 s ±1 s after removal of each sample from the refrigerator, the hammer complying with Table 2.2.1.6 is to be allowed to fall with impact energy.

Hammer Specification **Table 2.2.1.6**

Approximate energy (J)	Mass of hammer (kg)	Fall height (mm)
10	5.0	200 ±2

2.2.1.7 The impact is to be applied to the base, or the rung, in the first sample, to one of the side members in the second sample, and to the other side member in the third sample. In each case, the impact is to be applied to the centre of the face being tested.

2.2.1.8 After the test, the samples are to show no signs of disintegration and/or deformation that will impair the safety.

1.2.2 Safe Working Load (SWL) test

1.2.2.1 Cable trays/protective casings and joints are to be assigned a Safe Working Load (SWL) satisfying the following criteria, tested at the declared temperatures according to 2.1.1 above (see note):

- the maximum deflection is not to exceed $L/100$, where L is the distance between the supports,
- no mechanical defects or failure are observed when tested to 1.7 × SWL.

1.2.2.2 All loads are to be uniformly distributed (UDL) over the length and width of the samples as shown in Figure 2.2.2.2.

The loads are to be applied in such a way that a UDL is ensured even in the case of extreme deformation of the samples.

To allow for settlement of the samples, a preload of 10% of the test load unless otherwise specified, is to be applied and held for at least 5 min, after which the measurement apparatus is to be calibrated to zero.

1.2.2.3 The load is then to be gradually increased evenly longitudinally and transversely up to the test load continuously or when a continuous increase is impractical, the load may be increased by increments. These increments are not to exceed about a quarter of the safe working load. The load increments are to be distributed through the load plates longitudinally and transversely as evenly as is practical.

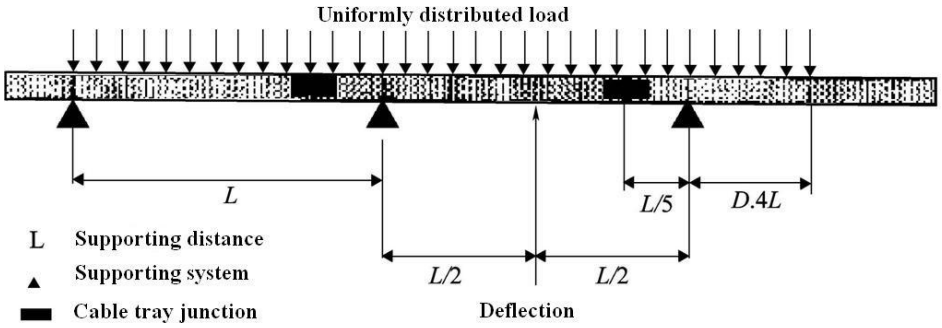

Figure 2.2.2.2 IEC 61537 Loading Test Procedure Summary

1.2.2.4 After loading, the deflection is to be measured at the points specified to give a practical mid-span deflection.

1.2.2.5 The samples are to be left and the deflections measured every 5 min until the difference between two consecutive sets of readings is less than 2 % with regard to the first set of the two consecutive sets of readings. The first set of readings measured at this point is the set of deflections measured at the test load.

1.2.2.6 When subject to the test load the samples, their joints and internal fixing devices, are to show no damage or crack visible to normal view or corrected vision without magnification.

1.2.2.7 The load is then to be increased to l.7 times the test load.

The samples are to be left and the deflections measured every 5 min until the difference between two consecutive sets of readings is less than 2% with regard to the first set of the two consecutive sets of readings. The samples are to sustain the increased loading without collapsing. Buckling and deformation of the samples is permissible at this loading.

Note: Alternatively, tests can be carried out:

- at any temperature within the declared range if documentation is available which states that the relevant structural properties of the materials as used within the system do not differ by more than 5% of the average between the maximum and minimum property values, or
- only at maximum temperature within the range, if documentation is available which states that the relevant structural properties of the materials as used within the system decrease when the temperature is increasing, or
- at maximum and minimum temperature only.

Tests are to be carried out for the smallest and largest sizes of cable tray lengths or cable ladder lengths, having the same material, joint and topological shape.

1.3 Fire properties

1.3.1 Flame retardant test

The cable trays/protective casings are to be at least flame retardant. They are to be tested in accordance with Table 2.3.1.

Flame Retardant Test

Table 2.3.1

Procedure according to	Test parameters	Other information
IEC 60092-101, or	– Flame application: 5 times 15 s each – Interval between each application: 15 s or 1 time 30 s	− The burnt out or damaged part of the specimen by not more than 60 mm long − Equipment design and the choice of materials is to reduce the likelihood of fire ensuring where surfaces of the specimen can be exposed to external fire they do not contribute to the fire growth
IEC60695-11-5	Test criteria based upon application	

1.3.2 Smoke and toxicity test

The cable trays/protective casings are to be tested in accordance with Part 2 of 2010 FTP Code adopted by IMO Resolution MSC.307(88) as amended by IMO Resolution MSC.437(99), or any international or national standard.

1.4 Special requirements

1.4.1 Resistivity test

Cable trays/protective casings passing through a hazardous area are to be electrically conductive. The volume resistivity level of the cable trays/protective casings and fittings is to be below 10^5 Ω and the surface resistivity is to be below 10^6 Ω. The cable trays/protective casings are to be tested in accordance with IEC62631-3-1 and IEC62631-3-2.
The resistance to earth from any point in these appliances is not to exceed 10^6 Ω.

CHAPTER 1GENERAL

Section 1 GENERAL PROVISIONS

1.1.1 General requirements

1.1.1.1 Ships with refrigerated cargo systems complying with the relevant requirements of Chapters 1 to 3 of this PART may be assigned the following class notations as appropriate:

CRS (× × Hold × ×℃, ××℃ Max. Sea Water)

— For ships fitted with refrigerated cargo installations, this notation is to be added after type notation, and minimum temperature(s) to be maintained by the installation at maximum sea water temperature stated and cargo area covered by the minimum temperature(s) are to be stated;

CF — For refrigerated installations for cargo fruits, this notation is to be added;

1.1.1.2 The certification requirements for and the products inspections related to refrigerated cargo systems are to comply with the relevant requirements of Chapter 3, PART ONE of the Rules.

1.1.2 Refrigerants

1.1.2.1 The provisions of this PART are applicable to the refrigerants listed in Table 1.1.2.1:

Refrigerants Table 1.1.2.1

Refrigerant No.	Chemical formula or composition	Blending Ratio
R717	NH_3	-
R134a	$CH_2F\text{-}CF_3$	-
R404A	CHF_2CF_3(R125)/CH_3CF_3(R143a)/CH_2FCF_3(R134a)	（44%/52%/4%）
R407C	CH_2F_2(R32)/CHF_2CF_3(R125)/CH_2FCF_3(R134a)	(23%/25%/52%)
R410A	CH_2F_2(R32)/CHF_2CF_3(R125)	(50%/50%)
R507A	CHF_2CF_3(R125)/CH_3CF_3(R143a)	(50%/50%)

1.1.2.2 Where other refrigerants are to be used, relevant information is to be submitted for approval.

1.1.2.3 In addition, consideration is to be given to the relevant provisions for the application scope of refrigerants specified by the flag State Administration.

1.1.3 Operating conditions

1.1.3.1 The refrigeration systems are to operate satisfactorily when the ship is under the following conditions:

(1) permanent list up to 15º, and permanent trim up to 5º;

(2) rolling: 22.5º, and pitching: 7.5º.

1.1.3.2 Where the refrigerating units are provided with centralized control or automatic controlling and monitoring systems, the equipment of such systems is to comply with the relevant requirements of Chapter 2, PART SEVEN of the Rules.

1.1.4 Special cases

1.1.4.1 Any proposed addition to or relaxation of the requirements of this PART in respect to ships engaged on voyages of short duration, to installations of small capacity, or to other special cases is subject to agreement of ISC. In such cases a service limitation may be made to the ship.

1.1.4.2 Cargo chambers are in general not to be refrigerated by the direct expansion pipe grid system when R717 is used as refrigerant. However, in the case of a ship engaged in restricted service where the total capacity of its refrigerated cargo chambers is less than 500 m^3, a direct expansion ammonia pipe grid system may be adopted.

1.1.5 Plans and documents

1.1.5.1 The following plans and documents are to be submitted for approval. Where necessary, additional plans and documents may be required:

(1) General arrangement of insulated chambers (including neighbouring tanks and holds);

(2) Detailed plans showing the construction of insulation within refrigerated chambers;

(3) Details of insulation of piping and supports;

(4) General arrangement of refrigerating machinery space;

(5) Ventilation details of refrigerating machinery space;

(6) Arrangement of air cooling system;

(7) Arrangements of air cooler defrosting and drainage;
(8) Arrangement of brine grids or refrigerant grids in refrigerated chambers and method of construction;
(9) Piping diagrams of refrigerant, brine and cooling water systems;
(10) Arrangements of drainage and ventilation in refrigerated chambers;
(11) Arrangement of temperature measuring system in refrigerated chambers;
(12) Sectional arrangement and performance data of refrigeration compressors, detailed dimensioned plans of reciprocating compressor crankshafts;
(13) Plans of condensers, air and brine coolers, oil separators, liquid receivers and other pressure vessels;
(14) Schematic diagrams of automatic control, safety and alarm systems (including the specifications, types and functions).

1.1.5.2 The following plans and documents are to be submitted for information:
(1) Specifications for refrigerating plant (including centralized control and monitoring) and for insulation of refrigerated chambers;
(2) Calculations for refrigerating capacity.

Note: Plans and documents of the products which have been approved by ISC need not be resubmitted for approval.

1.1.6 Novel arrangement and construction

1.1.6.1 Where the proposed construction of the refrigerating unit or refrigerated chambers is novel in design or involves the use of unusual material, details are to be submitted for approval, and special tests may be required when necessary.

Section 2 TESTS

1.2.1 Pressure tests

1.2.1.1 Pressure tests after completion of manufacturing
(1) On completion of manufacturing, components and parts exposed to the pressure of the refrigerants are to be subject to strength and leak tests as detailed in Table 1.2.1.1.

Test Pressure **Table 1.2.1.1**

Component or part	Strength test (hydraulic)	Leak test (pneumatic)
Pressure vessels	1.5*p*	1.0*p*
Compressors:		
Cylinders	1.5*p*	1.0*p*
Crankcase	1.5*p*	1.0*p*
Valves and fittings	2.0*p*	1.0*p*
Pressure piping, welded fabricated headers, air coolers, etc.	1.5*p*	1.0*p*

Notes: ① *p* is the design pressure, see Table 2.1.4.1.
② The leak test normally requires an air pressure to be applied to the component while submerged in water. Alternative methods for leak test may be considered if practicable.

(2) Components exposed to the pressure of brine or cooling water are to be hydraulically tested to 1.5*p*, but in no case less than 0.34 MPa.
(3) For components not suitable for hydraulic pressure test, the relevant test program is to be submitted to ISC for approval if air pressure test is adopted in lieu of hydraulic pressure test.

1.2.1.2 Pressure tests after installation on board ship
(1) For pressure piping welded in place, hydraulic tests of the welds are to be carried out at a test pressure of 1.5*p*.
(2) For pressure piping welded in place, the hydraulic tests required in 1.2.1.2(1) may be omitted provided non-destructive tests by ultrasonic or radiographic methods are carried out with satisfactory results on the entire circumferential butt welds.
Where ultrasonic tests have been carried out, the manufacturer is to provide the Surveyor with a test report confirming that ultrasonic examination has been carried out and that there were no indications of defects which could be expected to have a prejudicial effect on the service performance of the piping.
(3) After completion of the test required in 1.2.1.2(1) or (2), a leak test is to be carried out at a pressure given in Table 1.2.1.1, and to be witnessed by the Surveyor on site.

1.2.1.3 After tightness testing and before charging with refrigerant and oil, the complete plant is to be dried by a method of evacuation. The plant is to be evacuated until the minimum absolute pressure is reached as far as practicable, which is to be held constant until all water is evaporated. The plant is then to be refilled with air and the same procedure is to be repeated until no water is left in the plant.

1.2.2 Operation tests

1.2.2.1 Preparations for tests

(1) Before the operation test, all thermometers or temperature measuring equipment fitted in the refrigerated chambers or on the refrigerating machinery are to be checked for accuracy, and a statement is to be given to the Surveyor. The Surveyor may require a random test if deemed necessary.

(2) Pressure gauges and other measuring instruments are, before the operation test, also to be checked to the satisfaction of the Surveyor.

1.2.2.2 Air cooler fans are to be tested under working conditions after the air circulating system has been completed. During the test, the static pressure of air outlet, the volume of air circulated per minute, the fan speed and the power consumption are to be recorded. The air circulation arrangements in the chambers are to be checked.

A statement of the results for each chamber is to be handed to the Surveyor on completion of tests.

1.2.2.3 Refrigeration tests

(1) All refrigerating units of the refrigeration system are to be subject to refrigeration tests under working conditions. The refrigeration test is to be carried out for a period of at least 12 h after the chamber temperatures have been lowered to the minimum temperature as required. However, the total time is not to be less than 24 h throughout the test.

In general, the refrigeration test may be carried out with all chambers empty. The hatch covers, access plugs or doors and air refreshing arrangements are to be closed up and liquid sealed traps for scuppers are to be primed with brine.

(2) At the beginning of the refrigeration test, all refrigerating units are to be put into action. After the chamber has been cooled down to the design temperature, the test may be carried on with one of the units out of action in turn in accordance with the requirements of 2.1.3, Chapter 2 of this PART, provided that the minimum required temperature in the chamber is maintained constant throughout the test. During the test, each unit is to operate for about the same time.

(3) Refrigeration systems are to be tested during a period when a reasonable difference between the external and internal temperatures exists.

1.2.2.4 Thermal balance tests

(1) During the refrigeration test of newly designed refrigeration systems, a thermal balance test is to be carried out to the plant in combination with the insulated chambers, so as to determine the minimum chamber temperature as required in the design and the running conditions when the chamber temperature and the capacity of the plant are balanced. The thermal balance test is to be carried out in the presence of the Surveyor.

(2) When the chambers are cooled down to the minimum designed temperature, the thermal balance test is to be commenced after such a temperature has been maintained constant for a stabilizing period during which heat is removed from the insulation etc. The heat balance test is to last for 8 h. During the test, the temperature of the chambers is to be maintained at the minimum designed temperature and is not to be reduced by more than 1℃. The thermal test may be evaluated in accordance with the relevant programme or standard accepted by ISC.

On completion of the thermal balance test, a thermal balance calculation is to be carried out and the calculations are to be submitted.

1.2.2.5 Temperature rise test for the refrigerated cargo chambers

With the chambers at the minimum designed temperatures, a test for the capability of insulation is to be carried out. The temperature rises in the chambers are to be logged hourly for a period of 6 h.

The total temperature rise t_G (average value of all measuring points) after 6 h temperature rise test is not to be greater than that obtained from the following formula based on the initial temperature difference between the external and chamber temperatures at the beginning of the temperature rise test:

$$t_G = 0.24 t_F \quad ℃$$

where: t_F — initial temperature difference between the external and chamber temperatures, in ℃.

1.2.2.6 Other tests

(1) The air refreshing arrangements, if fitted, are to be tested under operating conditions.

(2) The automatic monitoring system is to be subjected to operation test. This test is, in general, to be carried out when the refrigerating machinery is in running condition, but the functions of alarm and safety devices may be tested under simulated fault conditions if necessary.

(3) Prior to, or on completion of the refrigeration test, the defrosting arrangements of the air coolers are to be tested as per different methods of defrosting. The drainage of bilge water in refrigerated chambers and defrosting water from air coolers may be carried out in conjunction with the refrigeration test.

CHAPTER 2 REFRIGERATING PLANT

Section 1 GENERAL PROVISIONS

2.1.1 Definition of a unit

2.1.1.1 A refrigerating unit comprises one (or a group of) independent refrigeration compressor(s), its driving motor and one gas condenser. Where a secondary refrigerant of brine is employed, the unit is also to include a brine cooler. It is usual for the compressor and the condenser of the refrigerating plant to be permanently connected to the installation with all necessary piping, fittings and electrical equipment.

Two or more refrigeration compressors driven by a single motor, or having only one condenser or brine cooler, are to be regarded as one unit. Where a refrigerating plant is provided for sub-cooling the liquid refrigerant of other units, but is not arranged for cooling the cargo chambers independently, it will not be regarded as a unit.

2.1.1.2 Refrigerating units for refrigerated cargo installations must be completely independent of any refrigerating machinery associated with air conditioning plant, or any domestic refrigerated installation, unless otherwise approved by ISC.

2.1.2 Number of units

2.1.2.1 In ships intended for the carriage of refrigerated cargo, at least two complete refrigerating units are to be provided.

2.1.2.2 In ships classed for restricted service where the total capacity of the refrigerated chambers is less than 1,500 m^3, only one complete refrigerating unit may be provided, but a standby compressor is to be fitted as an addition.

2.1.3 Refrigerating capacity

2.1.3.1 Where a ship is classed for unrestricted service and is intended to carry cargoes requiring different refrigerating temperatures, the refrigerating capacity of the units is to be calculated according to the minimum temperature required to be maintained by the various cargo chambers, with the outside seawater temperature being assumed not less than 32℃.

2.1.3.2 The refrigerating capacity of the refrigerating plant is to be sufficient to maintain the minimum design temperatures in the refrigerated cargo chambers when operating 24 h per day with any one of the refrigerating units out of operation.

2.1.3.3 In order to compensate for possible deterioration of the refrigerating capacity of compressors and the performance of insulation material over the life of the installation, the actual capacity of the refrigerating units is to have at least 5% excess capacity over that required for maximum design output.

2.1.3.4 Where the units are not connected in common to all refrigerated chambers, the refrigerating capacity of the unit serving each chamber (or a group of chambers) is to comply with 2.1.3.2 and 2.1.3.3 of this Section.

2.1.4 Design pressure of refrigerating plant

2.1.4.1 The design pressure of the high pressure side and the low pressure side of the refrigerating plant is to be not less than the values given in Table 2.1.4.1 respectively.

Design Pressure of Refrigerating Plant **Table 2.1.4.1**

Refrigerant	Design pressure of high pressure side① (MPa)	Design pressure of low pressure side② (MPa)
R717	2.2	1.7
R134a	1.4	1.1
R404A	2.5	2.0
R407C	2.4	1.9
R410A	3.3	2.6
R507A	2.5	2.0

Notes: ① High pressure side means the pressed parts of the compressor between its exhausting side and expansion valve.

② Low pressure side means the pressed parts from behind the expansion valve to suction valve of the compressor. Where the change-over of the plant (e.g. for defrosting) will put these parts under high pressure, they are to be designed and tested to the specified pressure of high pressure side.

2.1.4.2 Where any other refrigerant is used, the design pressure of high pressure side and low pressure side of the refrigerating plant is to be not less than the saturated vapour pressure at 56℃ and 46℃ respectively.

Section 2 REFRIGERATING MACHINERY

2.2.1 Reciprocating compressors

2.2.1.1 The diameter d of the crankshaft of a reciprocating compressor is not to be less than that determined by the following formula, when all cranks are located between two main bearings:

$$d = C\sqrt[3]{\frac{D^2P(\frac{S}{16}+\frac{ab}{a+b})Z}{7.85}} \text{ mm}$$

where: C — constant, to be determined in accordance with the specific arrangement of cranks and cylinders as shown in Table 2.2.1.1.

D — diameter of compressor cylinder, in mm;

P — design pressure as defined in Table 2.1.4.1 of this Chapter, in MPa;

S — length of piston stroke, in mm;

a — distance between inner edge of one main bearing and the centreline of the crankpin nearest the center of the span, in mm;

$a + b$ — span between inner edges of two main bearings, in mm;

Z — strength coefficient of material, to be determined by the following formula:

For steel:

$$Z = \frac{560}{R_m + 160}$$

For spheroidal or nodular graphite cast iron:

$$Z = \frac{700}{R_m + 260 - 0.059d_p}$$

For grey cast iron:

$$Z = \frac{700}{R_m + 260 - 0.069d_p}$$

where: R_m — specified minimum tensile strength of crankshaft material, in N/mm^2;

d_p — proposed minimum diameter of crankshaft, in mm;

Arrangement of Cranks and Cylinders **Table 2.2.1.1**

Number of crankpins	Number of cylinders per crank	Angle between adjacent cylinders (°)
1 or 2	2	45 60 90
3	2	45 60
4	2	45 60
1	3	45 60 90
2	3	45 60
3	3	45
1	4	45 60
2	4	45

For shafts having one cylinder per crank:

C = 1.0

For shafts having several cylinders, with 90° between adjacent cylinders on the same crankpin:

C = 1.05

For shafts having several cylinders, with 60° between adjacent cylinders on the same crankpin:

C = 1.18

For shafts having several cylinders, with 45° between adjacent cylinders on the same crankpin:

C = 1.25

2.2.1.2 Where the shaft is supported additionally by a centre bearing, the diameter is to be evaluated from the half shaft between the inner edges of the centre and outer main bearings. The diameter so found for the half shaft is to be increased by 6% for the full length shaft diameter.
2.2.1.3 The dimensions of crankwebs are to be such that bt^2 is to be not less than given by the following formulae:
For the web adjacent to the main bearing:

$$bt^2 = 0.4d^3$$

For intermediate webs:

$$bt^2 = 0.75d^3$$

where: b — breadth of web, in mm;

t — axial thickness of web which is to be not less than $0.45d$ for the web adjacent to the main bearing, or $0.60d$ for intermediate webs, in mm;

d — minimum diameter of crankshaft as required in 2.2.1.1 of this Section, in mm.

2.2.1.4 Fillets at the junction of crankwebs with crankpins or journals are to be machined to a radius r not less than $0.05d$. Smaller fillets, but of a radius not less than $0.025d$, may be used provided the diameter of the shaft is not less than the product of c and d, where: $c = 1.1 - 2r/d$, but not to be taken as less than 1.0.
2.2.1.5 Fillets and oil holes on the crankshafts are to be rounded to an even contour and smooth finish.
2.2.1.6 The crankcase of a trunk piston type compressor is to be designed to withstand an internal pressure at least equal to the maximum working pressure of the refrigerating system.

2.2.2 Strength of materials for the compressor crankshafts

2.2.2.1 The specified minimum tensile strength of castings and forgings for crankshafts is to be selected within the following limits:
(1) carbon and carbon-manganese steel forgings (normalized and tempered): 400 to 600 N/mm^2;
(2) carbon and carbon-manganese steel forgings (quenched and tempered): not exceeding 700 N/mm^2;
(3) carbon and carbon-manganese steel castings: 400 to 550 N/mm^2;
(4) spheroidal or nodular graphite iron castings: 370 to 800 N/mm^2;
(5) grey iron castings: not less than 300 N/mm^2.
Where it is proposed to use materials other than those listed above, details are to be submitted to for approval.

Section 3 PRESSURE VESSELS, PIPING, FITTINGS AND ACCESSORIES

2.3.1 Pressure vessels

2.3.1.1 Among refrigerants specified in 1.1.2.1 of Chapter 1 of this PART, pressure vessels for refrigerants R717 are to be constructed in accordance with the relevant provisions for Class I pressure vessels specified in Chapter 6, PART THREE of the Rules, and in ISC Rules for Materials and Welding. Other pressure vessels for refrigerants are to comply with the relevant requirements for Class II pressure vessels. The design pressure of pressure vessels for refrigerants is to comply with the requirements of Table 2.1.4.1 of this Chapter.
2.3.1.2 Where pressure vessel cylinders are made of steel tubes, these are to be seamless, electrical resistance welded or longitudinally submerged arc welded. Forge butt welded and spirally welded tubes are not to be used.
2.3.1.3 All pressure vessels with a design temperature below -40℃ and also vessels with a design temperature below 0℃ where the pressure/saturation temperature relationship does not apply, are to be manufactured from steels with mechanical properties, including notch toughness, suitable for the thickness and the lowest design temperature, and relevant information is to be submitted.

2.3.2 Pressure piping

2.3.2.1 All steel pressure pipes for the refrigerating plant are to comply with the relevant provisions specified in Chapter 2, PART THREE of the Rules. Among refrigerants specified in 1.1.2.1 of Chapter 1 of this PART, piping for refrigerants R717 is to be considered as Class I piping and class of pipings for other refrigerants is to comply with the relevant requirements of 2.1.5 of Chapter 2 of PART THREE of the Rules.

2.3.2.2 Pipes for the condensers are to be made of corrosion-resistant material. Pipes for condensers suitable for refrigerants R134a are to be made of corrosion-resistant copper.
Condenser tube plates are to be made of corrosion-resistant material on the seawater side, or alternatively, means capable of efficiently protecting against corrosion may be used.
2.3.2.3 Materials used for refrigerant, brine or seawater cooling piping and accessories are to be suitable for use with the liquids flowing within the pipes. Copper, brass, bronze and other copper alloy are not to be used for ammonia refrigerant. Magnesium alloy is not to be used for fluorine-substituted hydrocarbon refrigerant, and zinc is not to be used for ammonia and fluorine-substituted hydrocarbon refrigerants.
2.3.2.4 Refrigerant and brine pipes are to be seamless, of which the ammonia and brine pipes are to be of seamless steel.
Pipe fittings for the ammonia unit are to be made of steel, but malleable cast iron may be accepted. Pipe fittings for the fluorine-substituted hydrocarbon unit are to be made of steel or bronze.
2.3.2.5 The joints of steel refrigerant pipes are to be butt welded. Where the piping is galvanized in lengths and then joined by welding, the galvanizing is to be removed in way of the pipe ends before welding. Butt joints of copper pipes are to be brazed. If necessary, a particular length of piping may be connected by means of welded-on flanges having grooves in a raised face and with gaskets fitted between them, or by means of screw joint sleeves.
The gaskets for the pipe joints are to be approved by ISC.
2.3.2.6 The stop valves in the refrigerant piping are to be so constructed and arranged as to ensure safe renewal of the packings in the valve stuffing boxes without removing the refrigerant. The stop valves in the R134a refrigerant piping are to be constructed without stuffing boxes. If safety valves with soft stuffing boxes are adopted, they are to be provided with sealing glands.

2.3.3 Oil separators
2.3.3.1 Suitable oil separators with drains are to be provided in the refrigerant lines. If wire gauze is used in the separator, it is to be sufficiently robust and supported to prevent disintegration.

2.3.4 Filters
2.3.4.1 Suitable filters are to be provided in the refrigerant gas lines in the following positions:
(1) suction lines to compressors;
(2) liquid lines before expansion valves.
Wire gauze in filters is to be sufficiently robust and well supported to prevent disintegration. The material of wire gauzes is to be corrosion-resistant to refrigerants. The refrigerant piping is to be designed according to the characteristics of refrigerants, and pipelines are to be fitted with suitable means for separating, storing and purifying refrigerants.
2.3.4.2 The filters are to be so installed and arranged that the filters may be repaired and maintained without interrupting the supply of refrigerants.

2.3.5 Driers
2.3.5.1 Driers are to be fitted in R134a refrigerant systems and the arrangement is to be such that a drier can be by-passed, isolated and opened up without interrupting plant operations.

2.3.6 Thermometers
2.3.6.1 Thermometers are to be provided in systems of the refrigerating plant in the following positions:
(1) suction and delivery lines to compressors;
(2) inlet and outlet cooling water lines to condensers;
(3) brine inlet and outlet lines;
(4) refrigerant return pipes to air coolers of direct expansion type.

2.3.7 Pressure gauges
2.3.7.1 Pressure gauges are to be provided in systems of the refrigerating plant in the following positions:
(1) suction and delivery lines to compressors;
(2) delivery lines to brine pumps;
(3) all refrigerant return pipes to air coolers;
(4) lubricating oil inlets to compressors with pressure lubrication.

2.3.8 Liquid receiver and liquid level indication
2.3.8.1 Refrigeration system is to be provided with necessary liquid receivers, the capacity of which is to be such that all refrigerants filled in the refrigerating unit may be received during the maintenance and

repairing. If independent liquid receiver is provided for each refrigerating unit, the capacity of receiver is to be capable of receiving the refrigerant filled in the refrigerating unit.

2.3.8.2 Refrigerant liquid receivers are to be provided with liquid level indicators. If the level indicator constructed of glass is used, it is to be of the flat glass type. The indicators are to be provided with self closing valves in lower and upper connections so as to prevent the loss of refrigerant in the event of breakage of the indicator. All liquid level indications are to be capable of withstanding the maximum working pressure.

2.3.9 Cooling appliances

2.3.9.1 Chambers may be refrigerated by pipe grids on the ceiling, bulkheads and sides or by the circulation of air over air coolers.

2.3.9.2 Except in the case of chambers employing direct expansion pipe grids as specified in 1.1.4.2 of this PART, refrigeration in the chambers is to be effected by the circulation of brine. The brine pipe grids in each chamber are to be arranged in not less than two sections, each section is to be provided with valve(s) or cock(s) for closing. For a refrigerated chamber with a capacity of less than 300 m^3, one section may be permitted.

2.3.9.3 Steel piping used to convey brine or primary refrigerants within the refrigerated cargo chambers, or where embedded in insulation, is to be galvanized externally. Alternative equivalent methods of protecting the piping against corrosion may be accepted.

Brine piping and tanks are not to be galvanized on the brine side. However, if any parts of the brine system have been galvanized, the brine cooling and return tanks, if closed, are to be provided with a ventilating pipe or pipes led to the atmosphere in a location where no damage will arise from the gas discharged, and the ventilating pipes are to be fitted with wire gauze diaphragms which can readily be renewed.

Where the brine tanks are not closed, the compartments in which they are situated are to be efficiently ventilated.

2.3.9.4 Where the steel pipes used to convey primary or secondary refrigerants are connected by butt welds or by screwed couplings, the ungalvanized portion of the joints is to be suitably coated and taped after hydraulic testing to reduce the incidence of corrosion. The locations of the joints are to be marked on the outside of the insulation.

2.3.9.5 Where cooling pipes pass through watertight bulkheads or decks, the construction of penetrations and packings are to comply with the requirements of 3.1.1.5 of this PART.

2.3.9.6 Either brine or direct expansion of the refrigerant may be employed in the coils of air coolers for each of the chambers. The coils are to be arranged in not less than two sections, each of which is to be fitted with a valve capable of being readily isolated when necessary. The chamber is to be provided with at least one air pipe length and two grids in a certain distance. If the coils are not arranged in sections, at least two independent air coolers of single coil are to be fitted.

A single coil cooler may be provided for a chamber with a net capacity of less than 300 m^3.

2.3.9.7 Means are to be provided for effectively defrosting air coolers. Air coolers are to be provided with trays arranged to collect all condensate. The trays are to be provided with drains at their lowest points to enable the condensate to be drained away when the chambers are in service. The inside diameter of drains is not to be less than 40 mm.

2.3.9.8 Air coolers including fans and motors are to be, as far as practicable, separated from the refrigerated spaces loaded with cargo, and adequate space is to be provided such that both the fan and the motor may be readily removed for repair or renewal. Access for servicing only is required where several fans and motors are installed in a chamber.

2.3.9.9 In order to minimize the dehydration of the cargo and the frosting of the cooling appliances in the refrigerated cargo chambers, the plant is to be designed to maintain the required minimum temperature with a minimum of difference between the cooling medium and chamber temperatures.

2.3.10 Heating arrangements

2.3.10.1 Where it is intended to carry fruit cargoes which may be adversely affected by ambient temperatures which may be below the carrying temperatures, facilities for heating the cargo chambers are to be provided.

2.3.11 Air refreshing arrangements in cargo chambers

2.3.11.1 Where chambers are intended for the carriage of refrigerated cargoes requiring controlled ventilation, air refreshing means are to be provided. The positions of the air inlets are to be carefully selected to minimize the possibility of contaminated air entering the chambers. A distance of at least 3 m is to be maintained between inlet and exhaust vents so as to prevent them from being choked.

Chambers or spaces are to be provided with separate inlet and discharge vents. Each vent is to have a positive airtight valve capable of closing onto a seat.

2.3.12 Pumps

2.3.12.1 The refrigerating units are to be provided with at least two separate cooling water pumps, one of which may be a standby pump. This pump may be used for other purposes provided that it is of adequate capacity and its use on other services does not interfere with the supply of cooling water to the units.

2.3.12.2 Where the primary and/or secondary refrigerants are circulated in the system by pumps, a standby pump, which is not to be used for other purposes and capable of operating on all cargo chambers, is to be provided.

2.3.13 Sea connections

2.3.13.1 The refrigerant gas condenser cooling pump is to be supplied by two sea valves, one of which is provided on the port and the other on the starboard side.

2.3.14 Motive power

2.3.14.1 Where the refrigerating plant is electrically driven, the electrical power is to be supplied by at least two generators. Where any one of the generators is out of operation, the ratings of remaining generators are to be sufficient to maintain, at the seawater temperature specified in 2.1.3.1 of this Chapter, the required minimum temperatures specified in 2.1.3.2 or 2.1.3.3 of this Chapter for the refrigerated cargo chambers, and to ensure the simultaneous operation of other services essential for the propulsion and safety of the ship.

Section 4 CONTROL, ALARM AND SAFETY SYSTEMS

2.4.1 Automatic control for refrigerating plant

2.4.1.1 Where refrigerating plants are operated automatically, efficient manual controls are also to be provided so that manual control can be effected in the event of failure of the automatic control. The automatic control for the plant is to comply with the provisions set forth in 2.4.1.2 to 2.4.1.4 below.

2.4.1.2 The basic performances of all equipment in the refrigerating plant automatic control systems are to comply with the relevant requirements of Chapter 2, PART SEVEN of the Rules.

2.4.1.3 The refrigerating plant automatic control system is to cover the following:

(1) the control of the temperature in the refrigerated cargo chambers within the predetermined temperature limits;

(2) the control of the temperature of cooling air at the outlet not less than the minimum permissible temperatures when the chamber is air-cooled.

2.4.1.4 When the automatic thermostatic control mentioned in 2.4.1.3(1) above is changed over to manual control, the arrangement is to be such that thermostatic controls can be bypassed and isolated. As an alternative, duplicate thermostatically operated refrigerant control valves may be fitted, each valve is to be capable of the required duty and operable with the other out of action.

2.4.2 Alarm

2.4.2.1 The items of monitoring and alarms are not to be less than hose given in Table 2.4.2.1. Audible and visual fault alarms for the refrigerating plant are to be given at the appropriate control station or room.

Items of Monitoring and Alarms for the Refrigerating Plant① **Table 2.4.2.1**

No.	Item	Display	Alarm
1	Air temperature in the refrigerated cargo chambers	Temperature	High and low
2	Failure of air cooler fans	−	Failure
3	Bilge water level in the refrigerated cargo chambers	−	High
4	Condenser cooling water outlet temperature	Temperature	High
5	Compressor shutdown in the event of failure	−	Shutdown
6	Lubricating oil pressure of compressors	Pressure	Low
7	Suction pressure of compressors	Pressure	Low
8	Exhaust pressure of compressors	Pressure	High
9	Failure of seawater circulating pumps	−	Failure

No.	Item	Display	Alarm
10	Ammonia leakage in refrigerating machinery spaces	−	Leakage②
11	Brine cooler inlet and outlet	Temperature	High (outlet)
12	Failure of brine circulating pumps	−	Failure
13	Brine return tank level	−	Low

Note: ① Where the refrigerating machinery space is unattended, the fault alarms are to be relayed to the engineers' accommodation or other location where an engineer on duty stays.

② For setting of concentration for ammonia leakage alarm in refrigerating machinery space, see 2.5.5.3 of this Chapter.

2.4.3 Safety

2.4.3.1 The refrigerating plant is to be provided with safety systems to automatically shut down the compressors in the following events:

(1) excessively low pressure at the suction side of compressors;

(2) excessively high pressure at the delivery side of compressors;

(3) excessively low lubricating oil pressure in compressors;

(4) requirements specified in 2.5.5.3 of this Chapter for safety protection after ammonia leakage in the refrigerating machinery space;

(5) failure of seawater circulating pumps.

Section 5 LOCATION OF REFRIGERATING MACHINERY SPACE OR UNIT

2.5.1 Refrigerating machinery spaces

2.5.1.1 Where R717 is used as the refrigerant, the machinery compartment is to be isolated by gastight bulkheads and decks from any adjacent accommodation or working spaces.

2.5.1.2 Machinery using refrigerants other than R717 will not, in general, be subject to restriction on location. Where relatively large plants are adopted, they are to be installed in a separate compartment.

2.5.1.3 R717 is to be installed in dedicated gastight compartments. Except for small compartments, at least two access doors as apart from each other as possible, which are capable of being opened outwards and self-closed, are to be provided for R717 refrigerating machinery space.

2.5.1.4 In each R717 refrigerating machinery space at least two gas masks with canisters are to be provided near the entrance to that space and are to be kept in a box with glass window for immediate use when necessary.

2.5.1.5 The arrangements of the refrigerating machinery are to be such that all components are to be easily accessible for inspection or overhaul. Sufficient space is to be provided for cleaning and renewal of the tubes in brine coolers and condensers.

2.5.2 Ventilation and lighting

2.5.2.1 Any refrigerating machinery space is to be provided with an efficient mechanical ventilation system. The ventilation is to provide at least 30 air changes per hour in the refrigerating machinery space.

2.5.2.2 The suction ducts of the ventilation systems are to be constructed of steel or other equivalent material, and the exhaust ports of the ventilation systems are to be located in positions where no danger will arise. In the case of refrigerating machinery spaces other than R717, power exhaust ventilation systems are to be fitted with the suction inlets located at the lowest part of such spaces. Ventilation in R717 refrigerating machinery space is to comply with the relevant requirements in 2.5.3.1.

2.5.2.3 The mechanical ventilation for the refrigerating machinery space is to be capable of being controlled from two positions, and one of which is to be situated in a suitable position outside such space.

2.5.2.4 The fans in R717 refrigerating machinery space are to be of non-sparking type and the material and design of the fan are to comply with the requirements of 3.3.5 of Chapter 3, PART SIX of the Rules. Where the ventilation of R717 refrigerating machinery space is located within the ventilation corridor, the electrical motors are to be of certified safe type, and the explosion groups and temperature classes are not to be lower than IIA T1.

2.5.2.5 Sufficient lighting is to be provided in refrigerating machinery space. Lighting fittings required to be operating after the emergency shut-off of R717 refrigerating machinery space due to leakage of ammonia are to be of certified safe type, and the explosion groups and temperature classes are not to be lower than IIA T1 in accordance with 2.5.5.3(3) of this Chapter.

2.5.3 Use of R717 as a refrigerant

2.5.3.1 Compartments containing R717 machinery (including process vessels) are to be fitted with:

(1) a negative ventilation system independent of ventilation systems serving other ship spaces and the capacity of the refrigerating machinery space is to meet the requirements of 2.5.2.1; other suitable arrangements may be considered; Suction inlets of R717 refrigerating machinery space is to be located on the upper part of the compartment. The ventilation inlets of R717 refrigerating machinery space is to be from the safe area and the exhaust ports are to be lead to the safe location on the open deck;

(2) an emergency ventilation system independent of ventilation systems serving other ship spaces and the capacity of which is to provide at least 40 air changes per hour. If the capacity of the normal ventilation system in the refrigerating machinery space is increased to an amount of not less than 40 air changes per hour for that space, the emergency ventilation system may be dispensed with;

(3) if emergency water-spraying system is accepted in lieu of emergency ventilation system as equivalent, the emergency water-spraying system is to meet the requirements of 2.5.4 of this section; the emergency water-spraying system is to be capable of being operated from a position outside the refrigerating machinery space;

(4) a fixed R717 vapor detector system with alarms inside and outside the compartment;

(5) water screens above all access doors, operable manually from outside the compartment;

(6) an independent bilge system.

2.5.3.2 At least the following safety and protective equipment are to be provided outside of the R717 refrigerating machinery space and the storage location is to be marked for identification and restoration in the event of a refrigerant leak:

(1) two sets of protective clothing (helmet, face masks, boots, gloves etc.);

(2) two sets of independent respirators (at least for 30 min use);

(3) two goggles;

(4) two 30 kg bottles of boric acid;

(5) two emergency electric torches (to be certified safe type and the explosion groups and temperature classes are not to be lower than IIA T1);

(6) one electrical insulation resistance meter.

2.5.3.3 R717 piping is not to pass through accommodation spaces.

2.5.3.4 In case of R717 plants with a quantity of ammonia not greater than 25 kg, the plants are permitted to be located in the machinery space, provided that:

(1) the area where the R717 machinery is installed is served by a hood with a negative ventilation system, so as not to permit any leakage of ammonia from dissipating into other areas in the space;

(2) a water spray system is provided for the said area;

(3) the requirements in 2.5.3.1(2), 2.5.3.2(1) and 2.5.3.3 above are met.

2.5.4 Water-spraying system for R717 refrigerating machinery space

2.5.4.1 The system is to be independent and contains only fresh water, but may also be used for supply to the water screens.

2.5.4.2 The discharge nozzles in the space(s) protected are to be positioned such that the spray is directed over the entire area containing the ammonia refrigeration machinery. The spray volume of the water-spraying system is to be capable of absorbing the leaked ammonia.

2.5.4.3 The supply water of water-spraying system is to be pressurized. The pressurized system is to consist of two pumps and a tank which is to be fitted with adequate safety relief arrangements, pressure gauge(s), level control and level gauge.

2.5.4.4 Means are to be provided to automatically maintain the required pressure and the water level in the tank. In the event of low pressure or the low level, an audible alarm is to sound in the refrigeration machinery room and control room.

2.5.4.5 The water-spraying system is to be arranged to automatically start when the concentration of ammonia in the space exceeds 300 ppm.

2.5.4.6 If water-spraying system is fitted in the refrigerating machinery space, all electrical equipment in the space is to be to IP44 enclosure.

2.5.5 R717 vapor detection and alarm system

2.5.5.1 The detector is to be of a certified safe type, and the explosion groups and temperature classes are not to be lower than IIA T1 and to be suitable for the low temperature working environment.

2.5.5.2 The arrangement of R717 vapor detector is to meet the following requirements:

(1) The refrigerating machinery spaces; one detector per 36 m^2 of the space floor area.

(2) One detector in the exhaust duct of the refrigerating machinery space ventilation system.
(3) One detector in the access corridors leading to the ammonia refrigerating machinery spaces.
(4) One detector in the ammonia storage space.
2.5.5.3 The alarming and safety protection after detection of ammonia leak are to meet the following requirements:
(1) When the concentration of ammonia exceeds 25 ppm, the detectors are to activate alarms.
(2) When the concentration of ammonia exceeds 300 ppm, the detectors in the refrigerating machinery space are to automatically stop the refrigerating plant and automatically activate the emergency ventilation system.
(3) When the ammonia concentration exceeds 5000 ppm, all non-explosion proof electrical equipment in the refrigerating machinery space is to be cut off.

Section 6 SAFETY DEVICES

2.6.1 Relief valves and safety valves

2.6.1.1 A pressure relief valve and/or safety disc is to be fitted between each compressor and its gas delivery stop valve. The safety devices are to come into action in case of excessive refrigerant pressure, the discharge being led to the suction side of the compressor. No closing appliances are to be permitted in the backflow pipes.
2.6.1.2 The opening pressure or bursting pressure of relief valves and/or safety discs at the delivery side of compressors is to be not greater than the design pressure of high pressure side given in Table 2.1.4.1, according to different refrigerants.
2.6.1.3 Where the power of the compressor prime mover does not exceed 10 kW, the relief valves and/or safety discs at the delivery side of the compressors may be omitted.
2.6.1.4 All pressure vessels or other components of refrigerant systems which could become filled with liquid refrigerant and isolated are to be provided with safety discs and/or relief valves, the discharge being led to a safe place above deck. When the safety disc is fitted in front of the relief valve, the back of the safety disc is to be provided with a bulwark to ensure the function of the relief valve. When the safety disc is fitted behind the relief valve, a pressure gauge indicating the intermediate pressure is to be fitted between the relief valve and the safety disc.
2.6.1.5 In the fluorine-substituted hydrocarbon systems, the safety valves and safety discs may be substituted by fusible plugs having a fusion point of 65℃, provided that the individual capacity of the above-mentioned pressure vessels is less than 100 *l*.
2.6.1.6 The opening pressure or bursting pressure of relief valves and/or safety discs as required in 2.6.1.4 is to be not greater than the design pressure of the system or components given in Table 2.1.4.1.
2.6.1.7 Suitable safety valves are to be provided to the cooling water side of condensers and the brine side of evaporators where the discharge pressure from any cooling water pump or brine circulating pump in the circuit could exceed the design pressure of the piping or any component forming part of the cooling system.

2.6.2 Emergency drainage

2.6.2.1 The R717 systems are to be provided with emergency drain pipes so as to immediately drain off the ammonia overboard in case of accident. Stop valves fitted in such pipes are to be situated outside the refrigerating machinery spaces and to be placed in a sealed box with glass window. The outlets of the drain pipes at the ship's side are to be placed below the light ballast waterline, and are to be provided with non-return valves.

2.6.3 Emergency stopping devices

2.6.3.1 For a refrigerating plant using R717 refrigerant, the prime mover of the compressors is to be provided with an emergency stopping device which is to be situated outside the refrigerating machinery space, and provision is to be made for preventing the inadvertent touching by unauthorized persons.

2.6.4 Alarm buttons in the refrigerated cargo chambers

2.6.4.1 Alarm buttons are to be fitted in the refrigerated cargo holds/chambers for giving alarms to the refrigerating machinery space, engine room and navigation bridge in case of emergency.

CHAPTER 3 REFRIGERATED CARGO HOLDS/CHAMBERS

Section 1 DESIGN OF CARGO HOLDS/CHAMBERS

3.1.1 Airtightness of holds/chambers

3.1.1.1 Each individual hold/chamber is to be of steel construction throughout and hose-tested for tightness, or alternatively, air pressure test may be accepted.

Special consideration will be given to the construction of divisional bulkheads of materials other than steel, between refrigerated cargo holds/chambers, where the holds/chambers concerned are intended for cargo which will not taint or otherwise adversely affect the cargo in any other hold/chamber.

3.1.1.2 Hatch closing appliances, access doors, bilge and manhole plugs are to be made airtight. Where hatch covers or plugs are exposed to ambient conditions, they are to be provided with a double seal.

3.1.1.3 Air ducts and insulation linings are to be so constructed and fitted that moving air is prevented from entering the insulation. Special care is to be taken where cooling pipes, air refreshing ducts, fan supports, etc. protrude through the lining.

3.1.1.4 Refrigeration pipes passing through bulkheads or decks of refrigerated cargo holds/chambers are not to be in direct contact with the steelwork, and the holes through which they pass are to be true and of suitable finish for effectively sealing by the method intended so as to maintain the airtightness of the bulkheads or decks.

The temperature of ship's steelwork close to low temperature refrigeration piping is not to be lower than that acceptable for the steel grade.

3.1.1.5 Where cooling pipes pass through watertight deck plating and bulkheads, the fittings are to be both fire resisting and watertight. Refrigerating pipelines are to be effectively insulated outside the chambers they serve, except within insulated brine coolers and control rooms.

3.1.2 Air circulation

3.1.2.1 When frozen cargo is carried, provision is to be made for adequate circulation of air between the frozen cargo and all the insulation lining surfaces. When cooled cargo of a type which may generate heat or emit gas is carried, provision is to be made for the adequate circulation of air through all the stacks.

3.1.2.2 For the purpose of providing air passage in the refrigerated cargo holds/chambers, cargo battens fastened to or temporary dunnage added during cargo loading to the exposed vertical or near vertical surfaces of the insulation linings may be used. They are to be arranged to suit the air flow.

3.1.2.3 Adequate air flow is to be maintained between cargo and cooling grids, where fitted.

3.1.3 Galvanizing of fixtures

3.1.3.1 All steel bolts, nuts, hangers, brackets and fixtures which support or secure cooling appliances, insulation, meat rail, etc., are to be galvanized.

3.1.4 Oil-impervious coatings of oil tank tops and bulkheads

3.1.4.1 Before insulating the oil tank tops and bulkheads, successive coatings impervious to oil are to be applied. The total thickness of the coating required is to depend on the construction of the tank and the composition of the coating used.

3.1.5 Liquid-tightness

3.1.5.1 Tank top insulation in way of manholes and bilge hats is to be provided with a liquid-tight steel coaming to prevent seepage into the insulation.

Section 2 ACCESSORIES

3.2.1 Temperature measurement instruments in cargo holds/chambers

3.2.1.1 Each refrigerated cargo hold/chamber is to be provided with a suitable number of thermometers, and the exact number and positions of which are subject to approval.

The inside diameter of thermometer tubes is not to be less than 50 mm, and the tubes are not to be in contact with cold decks. Thermometer tubes with their flanges and covers are to be insulated from the deck plating.

Thermometer tubes are to be so arranged on weather decks that water will not run down the tubes when temperatures are being taken.
Where thermometer tubes pass through compartments other than those which they serve, they are to be efficiently insulated.
3.2.1.2 Where electrical remote reading thermometers are adopted for the refrigerated cargo chambers, they are to be fitted in accordance with the relevant requirements in 3.2.2 of this PART. Such thermometers are also to comply with the relevant requirements specified in Chapters 1 and 2, PART SEVEN of the Rules.
3.2.1.3 Where the hold/chamber is intended for the carriage of frozen cargo only, the temperature readings are to be accurate to within ±0.5℃ of the true temperature. Where the hold/chamber is intended for the carriage of fruit, the readings are to be accurate to within +0.2℃ to -0.1℃ of the true temperature in the range -3℃ to +3℃, and to +0.3℃ to -0.2℃ in other parts of the range.
For scale instruments, the scale deflection is to be not less than 5 mm/℃ with division markings enabling the indication to be estimated within 0.1 of a degree.

3.2.2 Installation requirements for remote reading temperature instruments
3.2.2.1 At least two instruments are to be provided for each refrigerating system, with the sensing elements so connected that in the event of a failure of any one instrument, it is to be ensured that other temperature instruments are capable of testing the temperature of each hold/chamber.
Where a data logger is installed and all the sensing elements are connected to this single instrument, at least one sensing element in each hold/chamber or in its circulating air system is to be connected to a separate instrument.
The display of data loggers is to be in digital form or other equally effective visual indication, registering to 0.1 of a degree.
Where the equipment controlling the temperature of the air delivered from the cooler is equipped with a temperature indicator, this indicator will be given consideration as a standby instrument provided that the readings are accurate to within ±0.5℃ of the true temperature.
3.2.2.2 Where galvanometers are fitted, two are to be provided for each indicating instrument and a checking resistance is to be fitted.
3.2.2.3 Where the instruments have individual power supply units, a spare power unit (e.g. transformer and rectifier or battery) is to be provided for each instrument.

3.2.3 CO_2 indication equipment
3.2.3.1 All holds/chambers designed for carriage of fruit in general are to be fitted with permanently installed equipment for indication of CO_2 content.

3.2.4 Sounding, air and drain pipes
3.2.4.1 All sounding pipes, whether for compartments or tanks, which pass through refrigerated spaces or the insulation thereof, in which the temperatures contemplated are 0℃ or below, are to be not less than 65 mm bore.
3.2.4.2 Sounding pipes to oil compartments are not to terminate within refrigerated cargo holds/chambers or in the fan and cooler rooms for these holds/chambers, nor are these pipes to terminate in enclosed spaces from which access is provided to refrigerated cargo holds/chambers or their fan and cooler rooms.

3.2.5 Drainage from refrigerated cargo spaces
3.2.5.1 Provision is to be made for the continuous drainage of the inside of all insulated holds/chambers and cooler trays.
3.2.5.2 Drains which are led from cooler trays situated in the hold/chamber are to be fitted with liquid sealed traps. The inside diameter of drains is not to be less than 38 mm.
3.2.5.3 Where drains from separate holds/chambers join a common main, the branch pipes are each to be provided with a liquid sealed trap.
3.2.5.4 The liquid sealed traps are to be of adequate depth, and arrangements are to be made for ready access to the traps for cleaning and refilling with brine.
3.2.5.5 Screwed plugs or other means for blanking off scuppers draining insulated holds/chambers and cooler trays are not to be fitted. If, however, it is specially desired to provide means for temporarily closing these scuppers, they may be fitted with shut-off valves controlled from readily accessible positions on a deck above the load waterline.
3.2.5.6 Drainage from compartments outside the insulated holds/chambers is not permitted to be led into the bilge of the latter.

Section 3 INSULATION

3.3.1 General requirements

3.3.1.1 All steel bulkheads and shell plating inside the refrigerated cargo holds/chambers are to be covered with insulation material. Metallic lining or other equivalents are to be fitted for the protection of the outer surface of the insulants. Such linings are to be constructed and fitted in accordance with 3.1.1.3 of this Chapter.

3.3.1.2 Insulation linings and air screens, together with supports, are to be strong enough to withstand the loads imposed by either refrigerated or general cargo.

3.3.2 Insulation material

3.3.2.1 The insulants, linings, sealants and paints are not to emit odours which may taint subsequent cargo.

3.3.2.2 The insulants used for the refrigerated cargo holds/chambers are to be suitably resistant to fire and resistant to flame spread. The materials used and their adhesives are to be subject to approval by ISC. If chemical foam type of insulation is proposed, the process is to be subject to approval by ISC and the insulants are to be tested according to the recognized standards (e.g.: GB8624-2012 class B2 and other equivalent standards).

3.3.2.3 The covering on the surface of insulant is to be with the same performance to resist fire and flame spread as that of insulants.

3.3.3 Fitting of insulation material

3.3.3.1 Steelwork is to be thoroughly cleaned and dried, and suitably coated against corrosion before insulation is applied.

3.3.3.2 The insulation is to be efficiently packed and, where it is of slab form, the joints are to be butted closely together and staggered. Unavoidable crevices are to be filled with insulating material, but bitumen is not to be used for filling crevices.

3.3.3.3 If the cargo to be loaded on to tank top insulation could cause damage to the lining, then additional protection is to be provided in way of the hatch and 0.6 m beyond. The protection may either be of a permanent or temporary nature.

3.3.4 Insulated plugs and panels

3.3.4.1 Insulated removable plugs are to be provided in the insulation where required for easy access to the bilge, bilge suction wells, cooler and chamber drains and tank manhole lids.

Insulated removable panels are to be provided for access to tank air and sounding pipes and drains. If necessary corrosion protection has been considered for the material of air, sounding and drains pipes, insulated removable panels may be dispensed with.

3.3.4.2 Insulation linings, bilge limbers and plugs, hatch covers and plugs and chamber access doors are to be made of water-vapour resisting material, or covered with such material and, where exposed to bilge or external conditions, they are to be sealed.

3.3.5 Insulation of pipes

3.3.5.1 Where the pipes, including scupper pipes, air pipes and sounding pipes, pass through refrigerated holds/chambers intended for temperatures of 0℃ or below, they are to be insulated from the steel structure, except in positions where the temperature of the structure is mainly controlled by the external temperature and will normally be above freezing point. Pipes passing through a deck plate within the ship side insulation, where the deck is fully insulated below and has an insulation ribband on top, are to be attached to the steel deck plating. In the case of pipes adjacent to the shell plating, metallic contact between the pipes and the shell plating or frames is to be avoided in so far as practicable.

The air refreshing pipes described in 2.3.11.1 need not, however, be insulated from the steelwork.

3.3.5.2 All pipes passing through the refrigerated cargo chambers mentioned in 3.3.5.1 above are to be well insulated.

CHAPTER 4 CARRIAGE OF REFRIGERATED CONTAINERS IN CARGO HOLDS

Section 1 GENERAL PROVISIONS

4.1.1 Class notation

4.1.1.1 The ships carrying refrigerated containers in cargo holds and complying with the requirements of this Chapter may be assigned the following class notation:

CRC (×× holds), AC f/WC

where: AC — air-cooled refrigerated containers;

f — the simultaneity factor for the refrigerating plant, refer to 4.3.2.3 of this Chapter;

WC — water-cooled refrigerated containers.

4.1.2 Plans and documents

4.1.2.1 The following plans and documents are to be submitted for approval:

(1) Calculations of hold ventilation;

(2) Arrangement of hold ventilation system;

(3) Arrangement of power sockets of refrigerated containers;

(4) Arrangement of hold temperature measuring and monitoring system (where fitted);

(5) Arrangement of refrigerated containers;

(6) Arrangement of safety passageway for personnel.

Section 2 ARRANGEMENT

4.2.1 General requirements

4.2.1.1 A passageway or platform for operators with a width of not less than 2 frames or 1 m, whichever is less, is to be provided on transverse bulkheads at a position corresponding to the height of each tier of containers. Handrail or portable rail is to be fitted at the outside of the passageway for the safety of operators.

4.2.1.2 Where torsion boxes are used as ventilation duct, the size of openings on longitudinal bulkheads is to be minimized as possible so as not to affect the overall longitudinal strength.

4.2.1.3 The deck of the passageway or platform for operators is to be of coarse lattice construction as possible to facilitate air flow.

4.2.2 Arrangement of ventilating equipment

4.2.2.1 In general, the supply fan and air inlet are to be arranged at the fore end of holds and the discharge fan and air outlet at the aft end.

4.2.2.2 The air inlet and outlet on deck are to be located as far apart from each other as is practicable. The height of ventilator coaming above deck is to comply with the relevant requirements of Load Line Convention. Where the ventilator is fitted in the masthouse, openings of a size sufficient for ventilation on both fore and aft end bulkheads are to be considered. Roller blinds are to be fitted on the openings to protect the masthouse from flooding. Suitable drainage means in the masthouse are to be considered for preventing water accumulation.

4.2.2.3 Supply fans or discharge fans may be arranged in holds if necessary.

4.2.2.4 Ventilation ducts are to be arranged as reasonably and uniformly as possible. Air supply ducts are to be extended to the refrigerating units of containers of the lowest tier or the bottom of hold as possible, and air vents are to be provided at each tier of stowed containers as possible. The air vents are to be directly facing the discharge fans of container condensers. The upper and lower air vents are to be spaced according to the general container size. Where stowage of superhigh containers is not specified, the spacing is to be determined according to the standard container size, i.e. approximately 2.5 m.

4.2.2.5 The ventilation duct and air inlet and outlet within a hold are to be evenly arranged as possible so that all spaces of the hold are well ventilated.

4.2.2.6 The ventilating equipment is to be capable of being switched on or off remotely from the bridge where it is to be clearly indicated whether the equipment is switched on or off.

4.2.3 Arrangement of refrigerated containers in hold

4.2.3.1 The distance between the containers and the longitudinal bulkhead is in general not to be less than 250 mm.

4.2.3.2 In case of mixed stacks of refrigerated and non-refrigerated containers, the refrigerated containers are to be stowed at the lower tiers and at both ends of the transverse bulkhead as possible. The refrigerating units of containers are to face the transverse bulkhead.

Section 3 VENTILATION WITHIN HOLDS

4.3.1 General requirements

4.3.1.1 This Section applies to cargo holds carrying refrigerated containers. In addition to the requirements of this Section, the corresponding requirements in this PART are to be complied with.

4.3.1.2 The ventilation of holds carrying refrigerated containers is to be determined mainly according to size, type, number of containers, type of refrigerated cargo to be carried and service area of the ship.

4.3.1.3 The design of ventilation is to comply with the following criteria:

External environment: Air temperature 35℃, relative humidity 70%, seawater temperature 32℃

Temperature in hold: Maximum permissible temperature 45℃.

4.3.2 Air supply required for holds carrying air-cooled refrigerated containers

4.3.2.1 Heat balance calculations are to comply with the following:

(1) The minimum power required for cooling of each refrigerated container:

20 ft 7.5 kW

40 ft 11.0 kW

(2) The effective power loss of supply fan is also to be taken into account.

4.3.2.2 For air supply required in each refrigerated container, the following values are applicable:

20 ft 3,100 m^3/h

40 ft 4,500 m^3/h

4.3.2.3 In general, the simultaneity factor for the refrigerating plant is to be taken as 1. Where the ventilation system of the hold is specially designed for refrigerated containers carrying sharp frozen products, the simultaneity factor may be taken as 0.7 ~ 0.8.

4.3.3 Air supply required for holds carrying water-cooled refrigerated containers

4.3.3.1 Heat balance calculations are to comply with the following:

(1) The minimum power required for cooling of each refrigerated container:

20 ft 1.5 kW

40 ft 2.1 kW

(2) The effective power loss of supply fan is also to be taken into account.

4.3.3.2 For air supply required in each refrigerated container, the following values are applicable:

20 ft 460 m^3/h

40 ft 700 m^3/h

4.3.4 Air inlet and distribution

4.3.4.1 The design of air inlet and distribution is to ensure that refrigerated containers will be effectively cooled under circumstances not related to loading conditions and the occurrence of hot spots is to be avoided. For the design conditions stated in 4.3.2 of this Section, it is recommended that air supply inlets be so arranged and distributed that air flow will directly face the refrigerating units of containers; for the design conditions stated in 4.3.3 of this Section, air supply is to be led into the lowest area in the hold.

4.3.5 Air inlets and outlets on deck

4.3.5.1 The air inlets and outlets of hold ventilation system are to be so arranged as to ensure air supply to refrigerated containers in holds under all weather conditions, and choking of air flow of inlets and outlets is to be avoided.

4.3.6 Bilge arrangement

4.3.6.1 Where the length of the hold carrying refrigerated containers is over 12 m, bilge drainage means are to be arranged both at the fore and aft parts of the hold.

4.3.7 Temperature measuring in holds

4.3.7.1 Temperature measuring devices are to be provided in the holds carrying refrigerated containers, and generally one measuring point each before, after, left of and right of containers above the second tier in each hold.

Section 4 ELECTRICAL INSTALLATIONS

4.4.1 General requirements

4.4.1.1 This Section applies to ships carrying refrigerated box containers in holds and on deck. In addition to the requirements of this Section, the corresponding requirements in PART FOUR of the Rules are to be complied with.

4.4.2 Capacity of power plant

4.4.2.1 Where refrigerated containers are supplied by the main power plant of the ship, the number and capacity of the main generating sets are to be such that in the event of any one generating set being stopped it will still be possible to supply those services necessary to provide normal operational condition of propulsion and safety as well as refrigerated containers.

4.4.2.2 For ships adapted to carry refrigerated containers, the containers may be supplied by a leased temporary power plant on deck. If impracticable, standby generating sets are not necessary for power supply of the containers subject to agreement of ISC.

4.4.2.3 For calculation of the capacity of generating sets, see 2.1.1.4 of Chapter 2, PART FOUR of the Rules.

4.4.3 Power distribution for refrigerated containers

4.4.3.1 The sockets of refrigerated containers are to be supplied by special distribution panel which is to be capable of indicating whether the sockets are live and which feeders are electrically connected.

4.4.3.2 The sockets of several containers may be combined to be supplied by one cable, but the connection line of each socket is to be provided with individual short-circuit and overload protection. The common power cable is to be determined according to the total capacity required and the diversity factor specified in 4.4.3.3 of this Section may be used if necessary.

4.4.3.3 Where no exact data are available, the following values may be used as diversity factor for the circuit of container sockets:

20 and less sockets: 0.8;
20 and more sockets: 0.65.

4.4.3.4 The sockets of refrigerated containers are to comply with the standard acceptable to ISC (see ISO 1496-2), and they are to be so fitted as to enable easy use and maintenance.

4.4.3.5 All socket outlets of refrigerated containers are to be provided with a switch, and be interlocked such that the plug cannot be inserted or withdrawn when the switch is in the ‘on’ position.

4.4.4 Monitoring of refrigerated containers

4.4.4.1 In general, the following conditions of refrigerated containers are to be monitored: FULL COLD, LOW COLD, NULL, DEFROST, HEAT and NO UNIT, actual temperature of air supply and return, set values, etc. The codes of containers for which alarms are initiated may also be monitored.

4.4.4.2 The information on monitoring is generally to be transmitted to the bridge or management center.

4.4.4.3 The automatic monitoring of refrigerated containers may be replaced by manual inspection where practicable.

CHAPTER 1 GENERAL

Section 1 GENERAL PROVISIONS

1.1.1 General requirements

1.1.1.1 For passenger ships and cargo ships of 500 gross tonnage and upwards engaged on international voyages, the fire detection, fire protection and fire extinction (hereinafter referred to as fire safety) are to comply with the relevant provisions of the International Convention for the Safety of Life at Sea, 1974 (hereinafter referred to as SOLAS Convention) and its amendments, taking into account the requirements of the flag Administration (if any), other than those for personnel qualification, management, operation and maintenance. Ships of less than 500 gross tonnage are to comply with the fire protection requirements of ISC Guidelines for Surveys of Non-convention Ships.

1.1.1.2 The performance standards and test methods for related systems and equipment are to comply with the relevant provisions of the International Code for Fire Safety Systems (hereinafter referred to as FSS Code) and the International Code for Application of Fire Test Procedures (hereinafter referred to as FTP Code).

1.1.1.3 In addition to the above-mentioned requirements, the fire safety of ships engaged on international voyages is to comply with the requirements of this PART.

1.1.1.4 The fire safety of ships engaged on international voyages is also to comply with the requirements, as appropriate, in PART ONE of the Rules.

1.1.1.5 Where necessary, the ship's operator/owner is to pay attention to the standards of other industries and organizations in respect to fire safety of ships. However, such requirements are not conditions for classification with ISC.

1.1.2 Plans and documents

1.1.2.1 The following plans and documents are to be submitted for approval:

(1) Details of fire division plan and fire protection typical nodes;

(2) Arrangement of fire insulation, arrangement of deck covering and arrangement of fire doors;

(3) Arrangement of ventilation system (including fire dampers and smoke dampers, if applicable);

(4) Arrangement of fixed fire extinguishing systems (including the fire extinguishing system for scavenge spaces of crosshead type diesel engines) together with extinguishing medium calculations;

(5) Arrangement of water fire-extinguishing systems;

(6) Arrangement of local water-based fixed fire-extinguishing systems and calculations (if applicable);

(7) Arrangement of fixed fire detection and fire alarm systems;

(8) Diagram of control system of quick-closing valve of fuel and lub. oil tanks;

(9) Fire control plan;

(10) Arrangement of inert gas systems (if applicable);

(11) Arrangement of oxygen and acetylene bottle including pipes (if applicable);

(12) Arrangement of liquefied petroleum gas cooking ranges and gas bottles including pipes (if applicable);

(13) Arrangement of oil-fired cooking ranges including pipes (if applicable);

(14) Arrangement of fire-extinguishing means for paint lockers and store rooms containing flammable liquids (if applicable);

(15) Arrangement of fire-extinguishing system of deep-fat cooking equipment (if applicable);

(16) Other plans and documents as deemed necessary by ISC.

1.1.2.2 The following plans and documents are to be submitted for information:

(1) Instruction manual or operating manual of the inert gas systems required by Chapter 15 of FSS Code.

1.1.3 Products certificate

1.1.3.1 The principal materials, equipment and installations used for the fire safety of ships are all to be provided with ISC appropriate products certificate, as detailed in Appendix 1B — List of Certification Requirements for Statutory Marine Products of Chapter 3, PART ONE of the Rules.

1.1.4 Basic requirements for arrangement of fire stations and systems

1.1.4.1 Any fixed fire-extinguishing systems and their stations, fire pumps, fire-extinguishing medium containers as well as other arrangements on board passenger ships are not to be arranged forward of the collision bulkhead.

1.1.4.2 Stations or centralized distribution manifolds for all fixed fire-extinguishing systems and their power sources are to be located in easily accessible positions and are not likely to be cut off by a fire in the spaces protected.
1.1.4.3 All fixed fire-extinguishing systems and their stations are to be clearly marked and the walkways leading to the stations are to be kept clear.

1.1.5 Fire safety measures for ships

1.1.5.1 The fire safety measures for tugs are to be dealt with as those for cargo ships of equivalent tonnage; the fire safety measures for ice-breakers, salvage ships and self-propelled working ships (such as dredges, floating cranes and other working ships etc.) are to be dealt with in accordance with the relevant requirements of the Code of Safety for Special Purpose Ships (resolution MSC.266(84)).
1.1.5.2 The fire safety of special purpose ships are to comply with the requirements in the Code of Safety for Special Purpose Ships, 2008, adopted by the International Maritime Organization by resolution MSC.266(84).
1.1.5.3 For non-propelled ships, the fire safety measures are to be provided by making reference to the relevant provisions in this PART according to the ship types and purposes.
1.1.5.4 Tankers carrying products having a flash point exceeding 60℃ (closed-cup test) are to be dealt with as cargo ships of equivalent tonnage, in addition to complying with the following requirements:
(1) Isolation valves are to be fitted in the fire main of the water fire-extinguishing system at the poop front in a protected position and on the tank deck at intervals of not more than 40 m to preserve the integrity of the fire main system in case of fire or explosion.
(2) Four fire-fighter's outfits are to be provided.
(3) In lieu of the fixed fire-extinguishing system for tanks, they are to be fitted with a fixed deck foam system complying with requirements.
1.1.5.5 Unless expressly provided otherwise, for the purpose of this PART, oil tankers mean tankers carrying crude oil or petroleum products having a flash point not exceeding 60℃ (closed-cup test), as determined by an approved flash point apparatus, and a Reid vapour pressure which is below the atmospheric pressure. Other tankers carrying liquids having the same fire hazard, e.g. liquefied gas carriers and chemical tankers, are also to comply with the requirements of ISC Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk and Rules for Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk, as appropriate.

1.1.6 Acceptance of substitutes

1.1.6.1 Where in this PART any particular type of appliances, apparatus, extinguishing media or arrangements is specified for any ship, any other type of appliance etc., not less effective may be allowed, provided the relevant calculations and test or application information are provided.

1.1.7 Miscellaneous

1.1.7.1 The arrangement of fuel oil, lubricating oil and other flammable oils is to be in compliance with the relevant requirements of Chapter 4, PART THREE of the Rules.
1.1.7.2 Unless expressly specified in this PART, the machinery, piping and pressure vessels used in fire safety systems are also to be in compliance with the relevant requirements of PART THREE of the Rules.
1.1.7.3 In addition to complying with the requirements of this PART, the electrical equipment and electronic devices in fire detection systems and other detection and alarm systems used for periodically unattended machinery spaces are to be in compliance with the relevant requirements of PART SEVEN of the Rules.
1.1.7.4 In addition to complying with the requirements of this PART, the electrical equipment and electronic devices used in fire safety systems are to be in compliance with the relevant requirements of PART FOUR of the Rules.
1.1.7.5 Fire extinguishing appliances are to be kept in good order and available for immediate use at all times.

CHAPTER 2 FIRE EXTINCTION SYSTEMS

Section 1 WATER FIRE-EXTINGUISHING SYSTEMS

2.1.1 Capacity of fire pumps

2.1.1.1 Where the water fire-extinguishing system is used for a deck foam system in tankers, the capacity of the fire pumps is to be sufficient to satisfy the requirements for operation of the deck foam system at its required output and the simultaneous use of two water jets with a throw of 12 m at the required pressure from the fire main.

2.1.2 Number and arrangement of fire pumps

2.1.2.1 Cargo ships are to be provided with fire pumps according to the following:

(1) in cargo ships of 500 gross tonnage and upwards but less than 1,000 gross tonnage, at least two power pumps are to be provided, one of which is to be an independent pump;

(2) in cargo ships of less than 500 gross tonnage, at least one independently driven fire pump is to be provided.

2.1.2.2 The arrangement of emergency fire pump is to comply with the requirements of Chapter 12 of the International Code for Fire Safety Systems (FSS Code).

2.1.3 Internal **diameter and pressure of fire main**

2.1.3.1 In general, the internal diameter of the fire main is not to be less than that required in the following formula:

$$d = \frac{L}{1.2} + 25 \quad \text{mm}$$

where: d — internal diameter of the fire main, in mm, but need not exceed 125 mm for cargo ships (except for ships designed to carry five and more tiers of containers on or above the weather deck) and 180 mm for passenger ships and in no case to be less than 50 mm;

L — length of ship measured between perpendiculars, in m.

2.1.3.2 In cargo ships of less than 1,000 gross tonnage, with the two pumps simultaneously delivering water through the specified nozzles, through any adjacent hydrants, a minimum pressure of 0.25 N/mm^2 is to be maintained at all hydrants.

Section 2 FIXED GAS FIRE-EXTINGUISHING SYSTEMS

2.2.1 General requirements

2.2.1.1 Means are to be provided for automatically giving audible warning of the release of fire-extinguishing medium into any space in which personnel normally work or to which they have access. The alarm is to operate for not less than 20 s before the medium is released.

Where automatic audible alarms are fitted to warn of the release of fire-extinguishing medium into cargo pump rooms onboard tankers carrying crude oil or petroleum products having a flash point not exceeding 60℃ (closed-cup test), they may be of the pneumatic type or electric type:

(1) if pneumatically operated, in cases where the periodic testing of such alarms is required, CO_2-operated alarms should not be used owing to the possibility of the generation of static electricity in the CO_2 cloud; air operated alarms may be used provided the air supply is clean and dry.

(2) if electrically operated, the alarms are to satisfy the requirements of Section 16, Chapter 2, PART FOUR of the Rules and the arrangements are to be such that the electrical actuating mechanism is located outside the cargo pump room, except where the alarms are certified intrinsically safe.

2.2.1.2 At each location of the means of control of any fixed gas fire-extinguishing system, there is to be sufficient illumination including emergency lights in addition to the main lights.

2.2.1.3 Storage rooms of extinguishing medium used for all fixed gas fire-extinguishing systems are to comply with the following requirements:

(1) Storage rooms of extinguishing medium are to be used only for the storage of containers and other components and parts of the systems.

(2) Storage rooms of extinguishing medium are to be provided with direct communications to the bridge or control station.

(3) The key to the storage rooms of extinguishing medium is to be stowed in a box with glass cover which is to be situated in an easily accessible and conspicuous position near the door.
(4) In each storage room of extinguishing medium there is to be displayed a clear and permanent schematic diagram showing the arrangement of the containers, manifold, piping and fittings relating to the release of extinguishing medium, together with the concise instructions for the operation of the system.
2.2.1.4 The release and alarm of the fixed gas fire-extinguishing system for the protection of machinery spaces, including the opening of the release box door for the purpose of test, is not to have automatic linkage with the system that shuts down the ventilation fans and oil pumps in machinery spaces.

2.2.2 High-pressure carbon dioxide systems

2.2.2.1 For cargo spaces the quantity of carbon dioxide available is, unless otherwise provided, to be sufficient to give a minimum volume of free gas equal to 30% of the gross volume of the largest cargo space so protected in the ship.
2.2.2.2 For machinery spaces the quantity of carbon dioxide carried is to be sufficient to give a minimum volume of free gas equal to the larger of the following volumes, either:
(1) 40% of the gross volume of the largest machinery space so protected, the volume to exclude that part of the casing above the level at which the horizontal area of the casing is 40% per cent or less of the horizontal area of the space concerned taken midway between the tank top and the lowest part of the casing; or
(2) 35% of the gross volume of the largest machinery space protected, including the casing.
Provided that the above-mentioned percentages may be reduced to 35% and 30% respectively for cargo ships of less than 2,000 gross tonnage; provided also that if two or more machinery spaces are not entirely separate they are to be considered as forming one space.
2.2.2.3 Where the volume of free air contained in air receivers in any space is such that, if released in such space in the event of fire, such release of air within that space would seriously affect the efficiency of the fixed fire-extinguishing system, an additional quantity of fire-extinguishing medium is to be provided. In general, for the space (e.g. engine room) fitted with starting air receivers, the effect upon free air volume in the air receivers is to be taken into account, when calculating CO_2. Or, if compressed air in the air receivers can be discharged into open space located outside the engine room through safe valves and its conducting pipes, the effect upon air receivers is not to be taken into account, when calculating CO_2.
2.2.2.4 When carbon dioxide is used as an extinguishing medium for the cargo pump room in tankers carrying cargo oil having a flash point not exceeding 60℃, the quantity of carbon dioxide is to be sufficient to give a minimum volume of free gas equal to 45% of the gross volume of the cargo pump room including the casing. For tankers carrying cargo oil having a flash point exceeding 60℃, if the cargo pump room is located in a separate space, it is to be treated as a machinery space.
2.2.2.5 For ro-ro spaces and vehicle spaces, other than special category spaces, which are capable of being sealed from a location outside the spaces, if a carbon dioxide system is fitted, the quantity of gas available is to be at least sufficient to give a minimum volume of free gas equal to 45% of the gross volume of the largest such cargo space which is capable of being sealed.
2.2.2.6 For the purpose of this paragraph the volume of free carbon dioxide is to be calculated at 0.56 m^3/kg.
2.2.2.7 Piping of carbon dioxide is to comply with the following requirements:
(1) Each connecting pipe led from each bottle head valve to the collecting pipe is to be provided with a non-return valve.
(2) The manifold connecting the collecting pipes and distribution manifold is to be provided with a pressure gauge having a maximum range of 1.5 times the working pressure.
(3) For machinery spaces of Category A or cargo pump rooms, the piping is to be provided with sufficient number and adequate size of nozzles so that 85% of carbon dioxide can be discharged into the space within 2 min. Approximately 10% of the total quantity of CO_2 is to be discharged to the protected space below the floor in engine room. For vehicle spaces and ro-ro spaces which are not special category spaces, the arrangements are to be such as to ensure that at least two thirds of the gas required for the relevant space are introduced within 10 min. For container and general cargo spaces (primarily intended to carry a variety of cargoes separately secured or packed) the fixed piping system is to be such that at least two thirds of the gas can be discharged into the space within 10 min. For solid bulk cargo spaces the fixed piping system is to be such that at least two thirds of the gas can be discharged into the space within 20 min. The system controls are to be arranged to allow one third, two thirds and the entire quantity of gas to be discharged based on the loading condition of the hold.
(4) The diameter of carbon dioxide piping leading to the spaces as stated in 2.2.2.7(3) above is to be determined by calculation in accordance with the expected quantity to be conveyed through the piping

based on the recognized standard①.The diameter of carbon dioxide piping in machinery spaces of category A and cargo pump rooms may also be determined from Table 2.2.2.7(4). The maximum quantities of carbon dioxide conveyed by the corresponding pipe diameters are given in Table 2.2.2.7(4).

Internal Diameter of Pipes and Conveyed Quantity Table 2.2.2.7(4)

Maximum quantity of carbon dioxide conveyed by the pipe (kg)	Internal diameter of pipe (mm)
60	15
100	20
135	25
275	32
500	40
1100	50
1600	65
2400	80
3300	90
4750	100
6800	114
9500	127
15250	152

(5) The minimum wall thickness of CO_2 pipes is given in Table 2.2.2.7(5). Slight difference from the thickness listed in the Table will be accepted for the purpose of selecting standard pipes.

Minimum Wall Thickness of CO_2 Pipes Table 2.2.2.7(5)

External diameter of pipe (mm)	Wall thickness (mm)	
	Piping forward of distribution manifold	Piping from distribution manifold to protected space (nozzles)
21.3 ~ 26.9	3.2	2.6
30.0 ~ 48.3	4.0	3.2
51.0 ~ 60.3	4.5	3.6
63.5 ~ 76.1	5.0	3.6
82.5 ~ 88.9	5.6	4.0
101.6	6.3	4.0
108.0 ~ 114.3	7.1	4.5
127.0	8.0	4.5
133.0 ~ 139.7	8.0	5.0
152.4 ~ 168.3	8.8	5.6

Notes:
1. Pipes are to be galvanized at least inside, except those fitted in the engine room where galvanizing may not be required.
2. For threaded pipes, where allowed, the minimum wall thickness is to be measured at the bottom of the thread.
3. The external diameters and thicknesses have been selected from ISO Recommendations R336 for smooth welded and seamless steel pipes. Diameter and thickness according to other national or international standards may be accepted.
4. For larger diameters the minimum wall thickness will be subject to special consideration.
5. In general the minimum thickness is the nominal wall thickness and no allowance need be made for negative tolerance or reduction in thickness due to bending.

(6) Distribution piping leading to cargo spaces is to have a bore of not less than 20 mm, and those leading to the nozzles are to have a bore of not less than 15 mm.

(7) CO_2 piping is to be provided with compressed air cleaning connections at its manifold or distribution manifold.

(8) CO_2 pipes are to be of seamless steel, except that flexible metallic pipes can be used as the connecting pipe led from each bottle head valve to the collecting pipe in accordance with recognized standards.

(9) For closed ro-ro cargo spaces, the piping arrangements are to be such that 2/3 of the gas required for a particular space can be discharged into the space within 10 min.

2.2.2.8 Carbon dioxide bottles are to comply with the following requirements:

(1) CO_2 bottles are to be of seamless steel. Each bottle is to be furnished with a certificate and to have on its body clear and permanent identification of weight, capacity, hydraulic test pressure, date of test, manufacturer' serial number and also inspection stamp.

(2) The bottles are to be wholly painted in bright colour but white in way of the markings, and with letters of "carbon dioxide (or CO_2)".

(3) The charging ratio for CO_2 bottles is to be suitable for the strength of the bottles and generally not to be more than 0.67 kg/L.

①E.g. Code of Design for Carbon Dioxide Fire Extinguishing System (GB50193-93(2010 edition)) or Fire Protection Equipment – Carbon Dioxide Extinguishing Systems for Use on Premises – Design and Installation (ISO 6183-2022), etc.

(4) Bottle head valves are to be associated with a steel or copper seamless tube having a diameter of 10 to 12 mm snipped off at its lower end and terminated near the bottom of the bottle.
(5) Bottle head valves are to be provided with safety diaphragms or other approved safety devices. The bursting pressure of the safety diaphragms is to be 18.6 ±1 MPa. For other approved safety devices, the relevant technical and test data are to be provided with, to demonstrate that the escape gas is ensured to be capable of being released when the bursting pressure reaches the same as above.
After bursting of safety diaphragms, the escape gas from bottle head valves is to be led to the open atmosphere through suitable piping. However, where the storage room for CO_2 cylinders is fitted with a dedicated mechanical ventilation system capable of providing at least 6 air changes per hour and keeping temperature in the room below 45°C and provided with a temperature alarm, such piping may be dispensed with.
(6) Bottles head valves are to be made of forged bronze or other suitable materials.
(7) CO_2 bottles are to be divided into groups according to the required quantity for different spaces to be protected. If releasing of the carbon dioxide is hand-operated directly by mechanical means, the number of bottles in each group is not to exceed 12.
2.2.2.9 Testing of carbon dioxide systems
(1) CO_2 bottles and bottle head valves are to be subjected to a hydraulic test of 24.5 MPa. Safety diaphragms are to be burst-tested in accordance with 2.2.2.8(5) by selecting 10% at random.
(2) On completion of fitting the bottle head valves, CO_2 bottles are to be subjected to an air-tightness test in the workshop to a pressure equal to the design pressure of the bottle.
(3) The pipes and valves of CO_2 piping systems are to be subjected to a hydraulic test with a pressure of at least 11.8 MPa for the distribution manifold and control valves and for pipe lengths between bottle head valves and the distribution manifold, and 1.0 MPa for pipe lengths between the distribution manifold and nozzles. The above tests may be carried out in workshop. On completion of the hydraulic test, CO_2 piping is to be subjected to an airtightness test using compressed air on board the ship to at least 0.69 MPa with the ends closed for checking the tightness of each connection.
(4) On completion of installation on board, the CO_2 piping system is to be function-tested with a pneumatic pressure not less than 2.47 MPa for checking the operation of releasing mechanism.

2.2.3 Low-pressure carbon dioxide systems

2.2.3.1 Where a low-pressure CO_2 system is fitted, the piping system is to be designed in such a way that the CO_2 pressure at the nozzles should not be less than $1N/mm^2$.

CHAPTER 3 FIRE SAFETY MEASURES

Section 1 SAFETY MEASURES FOR DUCT KEELS IN DOUBLE BOTTOM UNDER CARGO OIL TANKS

3.1.1 Safety aspects of double bottoms and duct keels under cargo oil tanks (corresponding to SOLAS regulation II-2/4.5.2.4)

3.1.1.1 Pipe ducts in the double bottom are to comply with the following requirements:

(1) They are not to communicate with the engine room.

(2) Provision is to be made for at least two exits to the open deck arranged at a maximum distance from each other. One of these exits fitted with a watertight closure may lead to the cargo pump room.

(3) In the duct, provision is to be made for adequate mechanical ventilation.

Section 2 FIRE PROTECTION OF MACHINERY SPACES

3.2.1 Measures to prevent the spills of oil fuel, lubricating oil, hydraulic oil, thermal oil and other combustible liquids

3.2.1.1 Tanks (corresponding to SOLAS regulation II-2/4.2.2.4)

(1) Air pipes from fuel oil tanks are to be led to a safe position on the open deck.

Air pipes from lubricating oil storage tanks may terminate in the machinery space, provided that the open ends are so situated that issuing oil cannot come into contact with electrical equipment or heated surfaces.

(2) Any overflow pipe is to have a sectional area of at least 1.25 times that of the filling pipe and is to be led to an overflow tank of adequate capacity or to a storage tank having space reserved for overflow purposes.

An alarm device is to be provided to give warning when the oil reaches a predetermined level in the tank, or alternatively, a sight glass with good illumination is to be provided in the overflow pipe to indicate when any tank is overflowing. Such sight glasses are to be placed on vertical pipes only and in readily visible positions.

3.2.1.2 Oil fuel gauge (corresponding to SOLAS regulation II-2/4.2.2.3.5.1 and 4.2.2.3)

(1) Short sounding pipes may be used for tanks other than double bottom tanks without the additional closed level gauge, provided an overflow system is fitted.

(2) Level switches may be used below the tank top provided they are contained in a steel enclosure or other enclosures not capable of being destroyed by fire.

3.2.1.3 Pump control (corresponding to SOLAS regulation II-2/5.2.2.3)

Controls of the oil pumps (e.g. oil transfer pumps, oil fuel unit pumps, lubricating oil service pumps, thermal oil circulating pumps and oil separators) required by Regulation II-2/5.2.2.3 of SOLAS are also to be provided from the compartment itself.

3.2.1.4 Oil fuel pipelines (corresponding to SOLAS regulation II-2/4.2.2.5.1)

Hose clamps and similar types of attachments for flexible pipes are not to be permitted.

3.2.1.5 Arrangements of oil fuel (corresponding to SOLAS regulation II-2/4.2.2 and 4.2.5.2)

Oil fuel in storage tanks is not to be heated to temperature within 10℃ below the flash point of the oil fuel, except that where oil fuel in service tanks, settling tanks and any other tanks in supply system is heated the following arrangements are to be provided:

(1) the length of the vent pipes from such tanks and/or a cooling device is sufficient for cooling the vapours to below 60℃, or the outlet of the vent pipes is located 3 m away from a source of ignition;

(2) the vent pipes are fitted with flame screens;

(3) there are no openings from the vapour space of the fuel tanks into machinery spaces (bolted manholes are acceptable);

(4) enclosed spaces are not located directly over such fuel tanks, except for vented cofferdams;

(5) electrical equipment is not fitted in the vapour space of the tanks, unless it is certified to be intrinsically safe.

Section 3 PROTECTION OF CARGO PUMP ROOMS ON OIL TANKERS

3.3.1 Measures to prevent explosions in cargo pump rooms on oil tankers

3.3.1.1 The requirements of 3.3.1.2 to 3.3.1.5 below apply to the cargo pump rooms of oil tankers where pumps for cargo, such as cargo pumps, stripping pumps, pumps for slop tanks, pumps for COW or similar pumps are provided. Pump rooms intended solely for ballast or oil fuel transfer, however, need not comply with these requirements.

3.3.1.2 Cargo pumps, ballast pumps and stripping pumps, installed in cargo pump rooms and driven by shafts passing through cargo pump room bulkheads are to be fitted with temperature sensing devices for bulkhead shaft glands, bearings and pump casings. These devices are to be capable of automatically effecting a continuous audible and visual alarm in the cargo control room or the pump control station.

3.3.1.3 Lighting in cargo pump rooms, except emergency lighting, is to be interlocked with ventilation such that the ventilation has been in operation for at least 5 min before switching on the lighting. Failure of the ventilation system is not to cause the lighting to go out.

3.3.1.4 A system for continuously monitoring the concentration of hydrocarbon gases is to be fitted. Sampling points or detector heads are to be located in suitable positions in order that potentially dangerous leakages are readily detected. When the hydrocarbon gas concentration reaches a preset level, which is not to be higher than 10% of the lower flammable limit, a continuous audible and visual alarm signal is to be automatically effected in the cargo pump room, engine control room, cargo control room and navigation bridge to alert personnel to the potential hazard.

(1) Where a system for sequential sampling is used for sampling of cargo pump rooms including exhaust ducts, the time between two samplings of a same position is to be reasonably short.

(2) For the number and arrangement of sampling points, appropriate consideration is to be given to the vapour density of carried cargo and the ventilation condition of tanks.

3.3.1.5 All cargo pump rooms are to be provided with bilge level monitoring devices together with appropriately located alarms. Bilge high-level alarms are acceptable as an alternative means for the level monitoring devices.

3.3.2 Gland seals in cargo pump room bulkheads

3.3.2.1 Where drive shafts pass through cargo pump room bulkhead or deck plating, gastight glands are to be fitted. The glands are to be efficiently lubricated from outside the cargo pump room.

3.3.2.2 The seal parts of the glands are to be of material that will not initiate sparks. The glands are to be constructed and fitted in accordance with the relevant requirements for fittings attached to watertight bulkheads, and if a bellows piece is incorporated in the design, it is to be pressure tested before fitting.

3.3.3 Cargo pump room ventilation

3.3.3.1 With the following arrangement of exhaust trunking there are to be 20 air changes per hour on the total volume of the cargo pump room:

(1) In the cargo pump room bilges just above the transverse floor plates on bottom longitudinals, so that air can flow over the top from adjacent spaces.

(2) The ventilator inlet of the cargo pump room is to be close to the bottom so far as practicable and above floors or bottom longitudinals. An emergency intake is to be fitted about 2 m above the cargo pump room lower grating (This emergency intake would be used when the lower intakes are sealed off due to flooding in the bilges.). The emergency intake is to have a damper fitted which is capable of being opened or closed from the exposed main deck and cargo pump room lower grating level.

(3) The foregoing exhaust system is in association with open grating floor plates to allow the free flow of air.

(4) A grating damper may be used between upper emergency and lower main ventilator openings, which can be shown to result in at least the required 20 air changes per hour through the lower inlets, can be adopted without the use of dampers. When the lower access inlets are closed, then at least 15 air changes per hour are to be obtained through the upper inlets.

3.3.4 Temperature of steam and heating media within the cargo area

3.3.4.1 On oil tankers, the steam and heating media temperature within the cargo area is not to exceed 220℃.

3.3.4.2 On gas carriers and chemical tankers, the maximum temperature is to be adjusted to take into account the temperature class of the cargoes.

3.3.5 Non-sparking fans

3.3.5.1 A fan is considered as non-sparking if in either normal or abnormal conditions it is unlikely to produce sparks.

3.3.5.2 Design criteria

(1) The air gap between the impeller and the casing is not to be less than 0.1 times the shaft diameter in way of the impeller bearing but not less than 2 mm. It need not be more than 13 mm.

(2) Protection screens of not more than 13 mm square mesh are to be fitted in the inlet and outlet of ventilation openings on the open deck to prevent the entrance of objects into the fan housing.

3.3.5.3 Materials

(1) The impeller and the housing in way of the impeller are to be made of alloys which are recognized as being spark-proof by appropriate test.

(2) Electrostatic charges both in the rotating body and the casing are to be prevented by the use of anti-static materials. Furthermore, the installation on board of the ventilation units is to be such as to ensure the safe bonding to the hull of the units themselves.

(3) Tests may not be required for fans having the following combinations:

① impellers and/or housings of nonmetallic material, due regard being paid to the elimination of static electricity;

② impellers and housings of non-ferrous materials;

③ impellers of aluminium alloys or magnesium alloys and a ferrous (including austenitic stainless steel) housing on which a ring of suitable thickness of non-ferrous materials is fitted in way of the impeller;

④ any combination of ferrous (including austenitic stainless steel) impellers and housings with not less than 13 mm tip design clearance.

(4) The following impellers and housings are considered as sparking and are not permitted:

① impellers of an aluminium alloy or magnesium alloy and a ferrous housing, regardless of tip clearance;

② housing made of an aluminium alloy or a magnesium alloy and a ferrous impeller, regardless of tip clearance;

③ any combination of ferrous impellers and housings with less than 13 mm design tip clearance.

(5) Type tests on the finished product are to be carried out in accordance with the requirements of ISC or an equivalent national or international standard acceptable to ISC.

Section 4 MISCELLANEOUS

3.4.1 Aluminium coatings on board oil tankers and chemical tankers

3.4.1.1 The use of aluminium coatings containing greater than 10 percent aluminium by weight in the dry film is prohibited in cargo tanks, cargo tank deck area, cargo pump rooms, cofferdams or any other area where cargo vapour may accumulate.

3.4.1.2 Aluminized pipes may be permitted in ballast tanks, in inerted cargo tanks and, provided the pipes are protected from accidental impact, in hazardous areas on open deck.

3.4.2 Tank cleaning openings

3.4.2.1 Ullage plugs, sighting ports and tank cleaning openings are not to be arranged in enclosed spaces.

3.4.3 Portable instruments for measuring oxygen and flammable vapour concentrations

3.4.3.1 Every oil tanker is to be provided with at least two portable gas detectors capable of measuring flammable vapour concentrations in air (%LEL) and at least two portable O_2 analysers. Alternatively, at least two gas detectors, each capable of measuring both oxygen and flammable vapour concentrations in air (%LEL), are to be provided.

3.4.3.2 In addition to the requirement in 3.4.3.1, for tankers fitted with inert gas systems, at least two portable gas detectors are to be capable of measuring concentrations of flammable vapours in inerted atmosphere (% gas by volume).

3.4.4 Pressurization of cargo tanks

3.4.4.1 PV valves to oil tanks are not to be set at pressures in excess of 0.021 MPa unless the tank scantlings have been specially considered.

3.4.5 Reinforced thickness of ballast and cargo oil piping

3.4.5.1 Ballast piping passing through cargo tanks and cargo oil pipes passing through segregated ballast tanks, as defined by regulation 19.3.6 of MARPOL Annex I, are to comply with the following requirements:
(1) The pipes are to be of heavy gauge steel of minimum wall thickness according to Table 3.4.5.1 hereunder with welded or heavy flanged joints the number of which is to be kept to a minimum.
(2) Expansion bends only (not glands) are permitted in these lines within cargo tanks for serving the ballast tanks and within the ballast tanks for serving the cargo tanks.

Minimum Wall Thickness of Pipes **Table 3.4.5.1**

Nominal diameter (mm)	Minimum wall thickness (mm)
50	6.3
100	8.6
125	9.5
150	11.0
200 and above	12.5

3.4.5.2 The thicknesses shown in Table 3.4.5.1 refer to carbon steel pipes.
3.4.5.3 Connection between cargo piping and ballast piping referred to above is not permitted except for emergency discharge as specified in the Unified Interpretation to regulation 1.18 of MARPOL Annex I. Nevertheless, provision may be made for emergency discharge of the segregated ballast by means of a connection to a cargo pump through a portable spool piece. In this case non-return valves are to be fitted on the segregated ballast connections to prevent the passage of oil to the ballast tanks. The portable spool piece is to be mounted in a conspicuous position in the cargo pump room and a permanent notice restricting its use is to be prominently displayed adjacent to it.
Shut-off valves are to be provided to shut off the cargo and ballast lines before the spool piece is removed.
3.4.5.4 The ballast pump is to be located in the cargo pump room, or a similar space within the cargo area not containing any source of ignition.

3.4.6 Bow and stern loading and unloading arrangements on oil tankers

3.4.6.1 Where a cargo hose connection is arranged outside the cargo tank area, the pipe leading to such connections is to be provided with means of segregation such as a spectacle flange, removable spool piece or equivalent① located within the cargo area. The space within 3 m of the manifold is to be considered as a dangerous area with regard to electrical or incendive equipment.

3.4.7 Direct loading pipes to oil tanker cargo tanks

3.4.7.1 In order to avoid the generation of static electricity when cargo is loaded direct into tanks, the loading pipes are to be led as low as practicable in the tank.

3.4.8 Cargo openings in the bottoms of topside tanks of ships carrying alternatively oil and grain

3.4.8.1 This requirement applies to ships carrying alternatively oil having a flash point not exceeding 60℃ or other cargoes.
When ships are designed to transport alternatively oil or dry cargoes, openings which may be used for cargo operations are not permitted in bulkheads and decks separating oil cargo spaces from other spaces not designed and equipped for the carriage of oil cargoes unless alternative approved means are provided to ensure equivalent integrity.

3.4.9 Emergency fire pumps in cargo ships②

3.4.9.1 In cargo ships, the room(s) where the pump and prime mover are installed is/are to have adequate space for maintenance work and inspections.

3.4.10 Prohibition of carriage in fore peak tanks of oil or other liquid substances which are flammable

3.4.10.1 In ships of 400 gross tonnage and above, compartments forward of the collision bulkhead are not

---

① Refer to IMO MSC/Circ.474.

② Emergency fire pumps in cargo ships are to additionally comply with the requirements of SOLAS regulation II-2/10 and Chapter 12 of FSS Code, as appropriate.

to be arranged for the carriage of oil or other liquid substances which are flammable.

3.4.11 Sea intakes for fire pump on ships with ICE Class

3.4.11.1 On ships with ICE Class at least one of the fire pumps is to be connected to a sea chest which is provided with de-icing arrangements.

3.4.12 Installation requirements for analysing units for continuous monitoring of flammable vapours

3.4.12.1 This requirement applies to gas analysing units of the sampling type located outside gas dangerous zones and fitted on board gas carriers or on board oil/chemical tankers.

3.4.12.2 Gas analysing units with non-explosion proof measuring equipment may be located in areas outside cargo areas, e.g. in cargo control room, navigation bridge or engine room when mounted on the forward bulkhead provided the following requirements are observed:

(1) Sampling lines are not to run through gas safe spaces, except where permitted under (5).

(2) The gas sampling pipes are to be equipped with flame arresters. Sample gas is to be led to the atmosphere with outlets arranged in a safe location.

(3) Bulkhead penetrations of sample pipes between safe and dangerous areas are to be of approved type and have same fire integrity as the division penetrated. A manual isolating valve is to be fitted in each of the sampling lines at the bulkhead on the gas safe side.

(4) The gas detection equipment including sample piping, sample pumps, solenoids, analysing units etc. is to be located in a reasonably gastight enclosure (e.g. a fully enclosed steel cabinet with a gasketed door) which is to be monitored by its own sampling point. At gas concentrations above 30% LFL inside the enclosure the entire gas analysing unit is to be automatically shut down.

(5) Where the enclosure cannot be arranged directly on the bulkhead, sample pipes are to be of steel or other equivalent material and without detachable connections, except for the connection points for isolating valves at the bulkhead and analysing units, and are to be routed on their shortest ways.

3.4.13 Fore peak ballast system on oil tankers

3.4.13.1 The fore peak tank can be ballasted with the system serving other ballast tanks within the cargo area, provided:

(1) the fore peak tank is considered as hazardous;

(2) the vent pipe openings are located on open deck at an appropriate distance from sources of ignition. In this respect, the hazardous zones distances are to be determined according to the hazardous zones defined in paragraphs 4.2.2.9 and 4.2.3.1 of IEC 60092-502: Electrical installations in ships - Tankers - Special features;

(3) means are provided, on the open deck, to allow measurement of flammable gas concentrations within the fore peak tank by a suitable portable instrument;

(4) the sounding arrangement to the fore peak tank is direct from open deck;

(5) the access to the fore peak tank is direct from open deck. Alternatively, indirect access from the open deck to the fore peak tank through an enclosed space may be accepted provided that:

① in case the enclosed space is separated from the cargo tanks by cofferdams, the access is through a gas tight bolted manhole located in the enclosed space and a warning sign is to be provided at the manhole stating that the fore peak tank may only be opened after it has been proven to be gas free; or any electrical equipment which is not certified safe in the enclosed space is isolated;

② in case the enclosed space has a common boundary with the cargo tanks and is therefore hazardous, the enclosed space can be well ventilated.

3.4.14 Arrangement of oxygen, acetylene cylinders

3.4.14.1 Storage of oxygen, acetylene cylinders is to meet the following requirements:

(1) The design, construction and approval of gas cylinders are to comply with the applicable requirements of PART THREE of the Rules or requirements of the recognized standards. Oxygen cylinders are to be provided with proper pressure relief device such as a fusible plug or a rupture disc.

(2) Pipes, pipe fittings, pipe joints and valves are to comply with the requirements of Class I piping systems. Materials for acetylene on the high-pressure side between the cylinders and the regulator are to be steel. Copper or copper alloys containing more than 65% copper are not to be used in the whole fixed acetylene piping. Materials for oxygen piping are to be of steel or copper. Materials for both oxygen and acetylene systems are to be corrosion resistant, all the pipes of the fixed piping are to be seamless drawn.

(3) The connections between fixed pipe sections are to be carried out by means of butt welding. Other types

of connections including threaded connections and flange connections are not permitted.
(4) Where there are two or more cylinders of each gas, separate dedicated storage rooms are to be provided for each gas.
(5) Storage rooms are to be constructed of steel, not located below the open deck, and be well ventilated and accessible from the open deck. The ventilation arrangement is to be separate from the ship's ventilation systems.
(6) Possible sources of ignition are not to be fitted in acetylene storage room and any electrical installation, if fitted, is to be of a certified explosion-proof type.
(7) Securing arrangements of gas cylinders are to be released easily and quickly for the expeditious removal of cylinders in the event of fire.
(8) Prominent and permanent "NO SMOKING" signs are to be displayed at the gas cylinder storage room.
(9) Where cylinders are stowed in open locations means are to be provided to:

① protect cylinders and associated piping from physical damage;

② minimize the likelihood of exposure to hydrocarbons;

③ ensure suitable drainage.

(10) If the pipes connecting the work station for oxyacetylene welding and gas storage room need to pass through deck or bulkhead, fixed pipes are to be provided between gas cylinder and work station for welding and they are not to pass through accommodation spaces, service spaces and control stations. Suitable protection is to be provided at the position passing through deck or bulkhead. Outlet stations of fixed pipes are to be fitted with shut-off valves.

3.4.15 Arrangement of liquefied-gas-fired ranges

3.4.15.1 If liquefied-gas-fired ranges are fitted in a galley, the following requirements are to be met:
(1) Ranges, gas cylinders, angle valves and pressure reduction valves, etc. are to be designed, manufactured and tested in accordance with applicable standards and codes.
(2) Unless separated from adjacent spaces by suitable fire division, the galley is to be situated above the main deck. Inside the galley no opening or stairway leading to the spaces below is allowed; or where an opening is arranged, a positive means of closing is to be provided.
(3) Liquefied gas ranges are to be fitted securely at predetermined positions. Means are to be provided to prevent shifting of ranges.
(4) Liquefied gas cylinders are to be positioned vertically and fixed securely. Fixed hoops are to be capable of being released easily and quickly. Cylinders are to be provided with wood blocks under the bottom to avoid impact.
(5) Steel liquefied gas pipe lengths are to be connected by welding. Threaded joints may be adopted for connecting ranges, valves, instrumentation etc. with pipes and valves. The joints are to be fitted with oil-resistant sealing washers or coated with binder to ensure gastightness.
The joints between rubber hoses and pressure reduction valves, ranges or steel pipes are to be cramped by metal clamps. The clamps are to be connected securely. They are to be capable of being easily fitted or removed and to ensure gastightness.
(6) For the pressure of strength test and tightness test on liquefied gas piping system, the requirements given in Table 3.4.15.1 are to be complied with.

Test Pressure of Piping **Table 3.4.15.1**

Liquefied gas piping	Test pressure	
	Strength test (in workshop) (MPa)	Tightness test (after installation on board) (MPa)
Piping from cylinder to pressure reduction valve	2.4	2.0
Piping from pressure reduction valve to range	0.2	0.1

(7) Storage spaces containing liquefied gas cylinders are to comply with the requirements of 3.4.14 of this Section and the fire safety requirements of 3.4.17 of this Section.
3.4.15.2 For galleys where oil or flammable gas is in use, their structure and arrangement are to comply with the following requirements:
(1) The oil fuel tank is to be located outside the galley and is to be fitted with approved means of filling and venting.
(2) The oil fuel or flammable gas supply to the burners is to be capable of being cut off from a readily accessible position outside the galley in the event of a fire occurring in the galley.

(3) Naked fire is not to be in use for ignition of oil fuel or flammable gas, except for galley stoves or water heaters. All pipelines for delivering oil fuel or flammable gas from containers to the stoves or water heaters are to be of steel or other approved materials. And safety appliances for automatic shutoff are to be provided so that they will automatically shut off oil fuel and flammable gas supply when the flame in the stoves goes out.
(4) Naked fire is not to be in use for warming oneself. Galley stoves and similar appliances are to be firmly fixed at their design positions, and means are to be provided to prevent them from shifting. Sufficient fire protection and insulation layers are to be provided under, around and over. The possibility of blocking up by combustion remains is to be kept to a minimum and cleaning tools are to be provided. Where the damper for limitation of the exhaust in the uptake is in a closed position, sufficient flow area is to be kept. The ventilator in way of the stove space is to be of sufficient cross-sectional area so as to supply the stoves with enough air for full combustion.
(5) Galleys are to be provided with ventilation appliances of sufficient capacity so as to purge the smoke and the gas liable to escape to a safe place.

3.4.16 Provision of fire extinguishers

3.4.16.1 In passenger ships, at least two portable fire extinguishers for each main vertical zone or enclosed space divided by watertight bulkheads, and for each floor of passenger spaces above the bulkhead deck are to be provided; and at least one for each galley and for store room is to be provided.
3.4.16.2 In cargo ships and tankers, at least two portable fire extinguishers for each deck and at least one for each galley are to be provided.

3.4.17 Fire-extinguishing arrangements for paint lockers and flammable liquid lockers

3.4.17.1 Paint lockers and flammable liquid lockers are to be provided with a fire-extinguishing arrangement enabling the crew to extinguish a fire without entering the space.
3.4.17.2 For paint lockers and flammable liquid lockers of a deck area of 4 m^2 and more, one of the fixed arrangements as specified below are to be provided:
(1) a CO_2 system, designed for 40% of the gross volume of the space;
(2) a dry powder system, designed for at least 0.5 kg powder/m^3;
(3) a pressure water-spraying or an automatic sprinkler system, designed for 5 $l/m^2 \cdot min$.
3.4.17.3 The pressure water-spraying system may be connected to the ship's fire main.
3.4.17.4 Systems or arrangements other than those mentioned in 3.4.17.2(1), (2), (3) may be accepted by ISC provided that relevant technical and test data are provided.
3.4.17.5 For paint lockers and flammable liquid lockers of a deck area of less than 4 m^2, which do not give access to accommodation spaces, a CO_2 portable fire extinguisher sized to provide a minimum volume of free gas equal to 40% of the gross volume of the space may be accepted in lieu of a fixed system as specified in 3.4.17.2. The extinguisher may be discharged through a port on the wall of the locker. The required portable fire extinguisher is to be stowed adjacent to the port. Alternatively, a port or hose connection may be provided to facilitate the use of fire main water.

CHAPTER 4 INERT GAS SYSTEMS

Section 1 GENERAL PROVISIONS

4.1.1 General requirements

4.1.1.1 This Chapter applies to ships fitted with the inert gas systems and nitrogen generator systems.

4.1.1.2 All types of inert gas systems are to comply with the following:

(1) An automatic control capable of producing suitable inert gas under all service conditions is to be fitted.

(2) Surveys are to be carried out at the intervals as required by PART ONE of the Rules.

4.1.2 Class notation

4.1.2.1 Inert gas systems complying with the requirements of this Chapter may be assigned the following class notation:

IGS

4.1.3 Plans and documents

4.1.3.1 In addition to the plans and documents required by relevant PARTs of the Rules, the following ones are to be submitted for approval:

(1) Details and arrangement of the inert gas generating plant including all control and monitoring devices;

(2) Arrangement of the piping system for distribution of the inert gas.

Section 2 INERT GAS SYSTEMS AND NITROGEN GENERATOR SYSTEMS OF DIFFERENT TYPES

4.2.1 Requirements for all inert gas systems on tankers, including chemical tankers, to which SOLAS regulation II-2/4.5.5.1 applies

4.2.1.1 An inert gas system complying with the applicable requirements of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93), is to be fitted on tankers to which SOLAS regulation II-2/4.5.5.1 applies. In applying the applicable requirements of Chapter 15 of the FSS Code, any use of the word "Administration" therein is to be considered as meaning ISC. The inert gas system is to be operated in accordance with SOLAS regulation II-2/16.3.3, as amended by resolution MSC.365(93). In applying SOLAS regulation II-2/16.3.3.2, paragraph 2.2.1.2.4 of Chapter 15 of the FSS Code is to be complied with.

4.2.2 Additional requirements for nitrogen generator systems on tankers, including chemical tankers, to which SOLAS regulation II-2/4.5.5.1 applies

4.2.2.1 Where a nitrogen generator system is fitted on board as required by SOLAS regulation II-2/4.5.5.1, the inert gas is to be produced by separating air into its component gases by passing compressed air through a bundle of hollow fibres, semi-permeable membranes or adsorber materials. The following requirements are to be complied with.

4.2.2.2 In addition to the applicable requirements of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93), the nitrogen generator system is to comply with SOLAS regulations II-2/4.5.3.4.2, 4.5.6.3 and 11.6.3.4.

4.2.2.3 A nitrogen generator is to consist of a feed air treatment system and any number of membrane or adsorber modules in parallel necessary to meet paragraph 2.2.1.2.4 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93).

4.2.2.4 The nitrogen generator is to be capable of delivering high purity nitrogen in accordance with paragraph 2.2.1.2.5 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93). In addition to paragraph 2.2.2.4 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93), the system is to be fitted with automatic means to discharge "off-spec" gas to the atmosphere during start-up and abnormal operation.

4.2.2.5 The system is to be provided with one or more compressors to generate enough positive pressure to be capable of delivering the total volume of gas as required by 2.2.1.2 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93). Where two compressors are provided, the total required capacity of the system is preferably to be divided equally between the two compressors, and in no case is one compressor to have a capacity less than 1/3 of the total capacity required.

4.2.2.6 The feed air treatment system fitted to remove free water, particles and traces of oil from the compressed air as required by 2.4.1.2 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93), is also to preserve the specification temperature.
4.2.2.7 The oxygen-enriched air from the nitrogen generator and the nitrogen-product enriched gas from the protective devices of the nitrogen receiver are to be discharged to a safe location on the open deck. “Safe location” needs to address the two types of discharges separately:
(1) Oxygen-enriched air from the nitrogen generator - safe locations on the open deck are:
① outside of hazardous area;
② not within 3 m of areas traversed by personnel;
③ not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets.
(2) Nitrogen-product enriched gas from the protective devices of the nitrogen receiver - safe locations on the open deck are:
① not within 3 m of areas traversed by personnel;
② not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.
4.2.2.8 In order to permit maintenance, means of isolation are to be fitted between the generator and the receiver.

4.2.3 Nitrogen / inert gas systems fitted for purposes other than inerting required by SOLAS regulations II-2/4.5.5.1 and 4.5.5.2
4.2.3.1 This paragraph applies to systems fitted on oil tankers, gas tankers or chemical tankers to which SOLAS regulations II-2/4.5.5.1 and 4.5.5.2 do not apply.
4.2.3.2 The systems are to comply with the requirements of 2.2.2.2, 2.2.2.4, 2.2.4.2, 2.2.4.3, 2.2.4.5.1.1, 2.2.4.5.1.2, 2.2.4.5.4, 2.4.1.1, 2.4.1.2, 2.4.1.3, 2.4.1.4, 2.4.2.1 and 2.4.2.2 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93).
4.2.3.3 The requirements of 4.2.2 of this Chapter apply to the systems except 4.2.2.1, 4.2.2.2, 4.2.2.3 and 4.2.2.5.
4.2.3.4 Materials used in inert gas systems are to be suitable for their intended purpose in accordance with the relevant requirements of ISC Rules for Materials and Welding.
4.2.3.5 All the equipment is to be installed on board and then tested under working conditions to meet the functional requirements and to be satisfactorily inspected by the Surveyor.
4.2.3.6 Two non-return devices as required by paragraph 2.2.3.1.1 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93) are to be fitted in the inert gas main. The non-return devices are to comply with the requirements of 2.2.3.1.2 and 2.2.3.1.3 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93); however, where the connections to the cargo tanks, to the hold spaces or to cargo piping are not permanent, the non-return devices required by paragraph 2.2.3.1.1 of Chapter 15 of the FSS Code, as amended by resolution MSC.367(93), may be substituted by two non-return valves.

Section 3 EXAMINATION AND TESTING

4.3.1 General requirements
4.3.1.1 The devices and equipment required by this Chapter are, after having been installed on board, to be tested under working conditions to confirm their performance.

CHAPTER 5 HELICOPTER FACILITIES

Section 1 GENERAL PROVISIONS

5.1.1 Application

5.1.1.1 This Chapter applies to all ships requesting the class notation specified in 5.1.2 below and fitted with areas and facilities for normal takeoff and landing of helicopters.

5.1.1.2 Helicopter deck facilities covered by this Chapter mean all deck structure, fire-fighting appliances and other equipment necessary for the safe operation of helicopters as well as any refueling and hangar facilities.

5.1.1.3 Helicopter deck structure, strength and arrangement, and related plans and documents to be submitted for approval are to comply with the requirements of Section 18, Chapter 2, PART TWO of the Rules.

5.1.2 Class notation

5.1.2.1 Ships complying with the requirements of this Chapter may be assigned the following class notation:

Helicopter Facilities

5.1.3 Plans and documents

5.1.3.1 The following plans and documents are to be submitted for approval:

(1) Arrangement of structural fire protection of helicopter deck, including fire division, means of escape, openings, drainage facilities;

(2) Arrangement of fire-fighting appliances provided for helicopter deck, including calculations of quantity of extinguishing agents to be used;

(3) Arrangement of helicopter refueling facilities and systems, where fitted.

5.1.4 Fire safety of helicopter deck

5.1.4.1 The fire prevention and fire extinction of helicopter deck is to comply with the requirements of SOLAS regulation II-2/18, other than those for personnel qualification, management, operation and maintenance.

5.1.4.2 Where the helicopter deck forms a part of the strength deck or a hatch cover, aluminum or other low melting point metal construction is not to be used.

5.1.4.3 The means of escape required for the helicopter deck may be used as working access for crew, provided the access is maintained clear.

5.1.4.4 Where the helicopter deck is of aluminum alloy that is made equivalent to steel, the drainage facilities thereof may also be made of aluminum alloy.

CHAPTER 1 GENERAL

Section 1 GENERAL PROVISIONS

1.1.1 General requirements

1.1.1.1 This PART applies to automated systems for machinery and electrical installations installed on sea-going ships.

1.1.1.2 The automated system in this PART covers control, safety and alarm systems (including displays).

1.1.1.3 Ships with different levels of automation complying with the requirements of this PART may be assigned the following class notations:

(1) AUT−0 — indicating that the ship's propulsion plant can be remotely controlled from the bridge control station with the machinery spaces (including engine room centralized control station or room) periodically unattended;

(2) MCC — indicating that the machinery and electrical installations are capable of being operated with continuous supervision by watch-keepers from a centralized control station or room in the engine room;

(3) BRC — indicating that the ship's propulsion plant can be remotely controlled from the bridge control station with the engine room attended by watch-keepers.

1.1.1.4 Ships with automated systems complying with the requirements of this PART are to be adaptable to all sailing conditions, including maneuvering.

1.1.1.5 The safety of the ships with automated systems complying with the requirements of this PART is to be same as that of the ships with machinery spaces being attended. Means are to be provided to ensure that the machinery and electrical equipment can be manually and effectively operated from a local position in case of failure of the automated systems.

1.1.2 Definitions

1.1.2.1 For the purpose of this PART:

(1) *Automatic control* means self-regulating control carrying out predetermined orders to operate the machinery without action by an operator.

(2) *Remote control* means control of a device by an operator from a distance through mechanical, electrical, electronic, pneumatic, hydraulic, electromagnetic (radio) or optical means or combination thereof.

(3) *Local control* means direct manual control by an operator of machinery through a device located on or adjacent to the controlled machinery.

(4) *Control stations* (*rooms*) means spaces fitted with monitoring means capable of controlling the machinery and electrical installations. They are mainly divided into four categories as follows in this PART:

① *centralized control station* (*room*) *of engine room* (abbreviated to ISC) means a control station (room) in which all monitoring means for automated equipment in engine room are concentrated;

② *bridge control station* (abbreviated to BCS) means a control station monitoring the propelling plant and other equipment in bridge;

③ *local control station* (abbreviated to LCS) means a control station where machinery and electrical installations are locally controlled;

④ *other control stations* mean control stations except the above-mentioned three ones.

(5) *Safety systems* mean systems which will operate automatically for safeguarding the machinery or electrical equipment in question in the following three modes of operation in case of serious faults endangering the main propulsion machinery, boilers, electric generating plants and other essential machinery or electrical equipment:

Mode a: immediate shutdown, e.g. emergency stop of main engines, emergency cutoff of boiler fuel oil supply and emergency cutoff of electric power supply to consumers. And such machinery or equipment is not to be put into operation again if without the manual resetting;

Mode b: the operation of the machinery is temporarily adjusted to the prevailing conditions, e.g., by reducing the output or rotation speed of the machinery;

Mode c: the normal operating conditions are restored by starting of standby machinery.

(6) *Alarm* means a visual and audible signal of a predetermined out-of-limits parameter for the monitored machinery or system, which can identify the particular fault condition and its location within the machinery spaces, which can identify the particular fault condition and its location within the machinery spaces.

(7) *Group alarm* means a common alarm activated by any abnormal conditions of the monitored machinery or system.

(8) *Fail-safe principle* means that upon failure or malfunction of a component or system, the output automatically reverts to a predetermined design state of least critical consequence.
(9) *Override* means the special control measures for the skipping of a certain procedure or a certain safeguard action so as to effect compulsory operation to the machinery or electrical equipment for a short period to ensure the safety of the ship.
(10) *Emergency shutdown device* means a device independent of any control system and intended for manual activation in an emergency to stop the operation of machinery and electrical installations, e.g. emergency stop button of main engines, emergency cutoff button of boiler fuel oil supply and emergency cutoff button of electric power supply to consumers.
(11) *Redundancy design* means standby technical means to be used in case of system or equipment fault, by which a corresponding function can be taken over to continue an action or an original function is restored to continue the operation condition.
(12) *Node* means a point of interconnection to a data communication link.
(13) *Network* means a communication net for data transfer and exchange between computers.
(14) *Major modification* means one of the following cases or a combination thereof which will cause a substantial change to functions or safety features of an onboard computer system (excluding peripherals):

① change of hardware configuration;

② update of software;

③ alteration of network (including topology structure).

1.1.3 Plans and documents

1.1.3.1 Where a ship is intended to be assigned a machinery notation, the following plans and documents associated with control, alarm (display) and safety systems covered by this PART are to be submitted for approval:
(1) List of monitored and display points;
(2) List of alarm points (including display position and mode of alarms in the control station/room);
(3) Items of safety systems;
(4) Schematic diagrams of (electric, pneumatic, hydraulic) power supply to automated systems.
1.1.3.2 Additional plans and documents are to be submitted for approval as deemed necessary by ISC.

1.1.4 Certification of products

1.1.4.1 For certification requirements for the equipment and installations used in automated systems of a ship, see for details in Appendix 1A — List of Certification Requirements for Classed Marine Products of Chapter 3, PART ONE of the Rules.

1.1.5 Trials

1.1.5.1 The automated systems together with the associated machinery and electrical equipment are to be subject to mooring and sea trails in accordance with a test program approved by ISC for ascertaining the normal working of the whole system.
1.1.5.2 The setting of alarm points of automated systems and the preset parameters of safety systems which are determined in compliance with the requirements of the Rules as shown by the trials are to be recorded and maintained onboard for information.

CHAPTER 2 BASIC REQUIREMENTS

Section 1 GENERAL PROVISIONS

2.1.1 Environmental conditions

2.1.1.1 The automated systems are to operate satisfactorily within the ambient air temperatures as specified in 1.2.1.1(1) of Chapter 1, PART FOUR of the Rules.

2.1.1.2 The automated systems are to operate satisfactorily under the following conditions of relative humidity:

95% ± 3% at temperatures up to +45°C;

70% ± 3% at temperatures higher than +45°C.

2.1.1.3 The automated systems are to operate satisfactorily under the vibration conditions listed in Table 2.1.1.3. Where resonance occurs in the following frequency ranges and exceeds the required values, suitable means are to be provided for vibration damping.

Vibration **Table 2.1.1.3**

Location of installation	Parameters of vibration	
General space	2.0 ~ 13.2 Hz Amplitude ±1 mm	13.2 ~ 100 Hz Acceleration ±0.7 g
On reciprocating engines (e.g. diesel engines, air compressors) and other similar spaces	2.0 ~ 25 Hz Amplitude ±1.6 mm	25 ~ 100 Hz Acceleration ±4.0 g
Other special locations, e.g. exhaust pipes for (particularly medium or high speed) diesel engines	40 ~ 2,000 Hz Acceleration ±10.0 g (temperature 600°C)	

2.1.1.4 The automated systems are to operate satisfactorily under inclination and rolling conditions in all directions from the mounting position up to 22.5° (period 10 s) and under linear vertical acceleration of ±9.8 m/s^2.

2.1.1.5 The automated systems are to be suitable for the normal conditions encountered on board ships, e.g. salt air, oil-laden atmosphere, mould and dust.

2.1.2 Other working conditions

2.1.2.1 The automated system is to comply with the requirements of paragraphs 1.2.2 and 1.2.3 of Section 2, Chapter 1, PART FOUR of the Rules.

2.1.2.2 The automated system is to have necessary electromagnetic compatibility.

2.1.2.3 The hydraulic and pneumatic equipment of automated systems is to operate satisfactorily under pressure variations in the system by ±20% of the rated values and is not to be damaged by transient pressure rise up to 1.5 times the rated pressure.

2.1.3 Fail-safe

2.1.3.1 Control systems, alarm systems and safety systems are to be designed on the fail-safe principle. The fail-safe principle is to be applied on the basis not only of the automated system itself and its associated machinery, but also of the whole machinery installation and the safety of the ship and personnel.

2.1.3.2 The design of the control system, alarm system and safety system is to be such that a failure in the operation will not cause other failures and will, so far as possible, lead to the least dangerous condition of the controlled process.

2.1.3.3 The automatic control and remote control systems are to ensure continuous, effective and reliable operation.

2.1.4 Independence

2.1.4.1 Control, safety and alarm systems are to be designed or rendered to function independently of each other so that a failure or malfunction in one or two of these systems will not prevent the other system(s) from operating.

2.1.4.2 In any case, a safety system of mode a is to function independently of control and alarm systems so that a failure or malfunction in these systems will not prevent the safety system from operating. For the safety systems of modes b and c, complete independence of other control and alarm systems is not required.

2.1.4.3 Safety systems of different units of the machinery plant are to be independent. Failure in the safety system of one part of the plant is not to interfere with the operation of the safety system in another part of the plant.

2.1.5 Examination and lock-in

2.1.5.1 The functions of control, safety and alarm systems are to be capable of being examined. Where the settings, e.g. sensitivity and limiting values of the control, safety and alarm equipment may be regulated, these regulated values are to be such that they may be easily examined, identified and locked-in.

2.1.6 Power supply

2.1.6.1 The safety and alarm systems and control systems (e.g. automated systems of an electric generating plant) requiring continuous use in the event of a failure of normal power supply are to be capable of being automatically changed over to an independent standby power supply. The standby power supply may be an accumulator battery, with a capacity at least sufficient for a period of supply of 30 min. Where such systems could be adversely affected by an interruption in power supply, change-over to the standby power supply is to be achieved without a break.

2.1.6.2 A visual and audible alarm is to be given in the event of a failure of power supply① for safety system, alarm system and control system.

2.1.6.3 Control system, safety system and alarm system are to be supplied by independent final sub circuit and protected against short circuit and overload.

Section 2 CONTROL SYSTEMS

2.2.1 General requirements

2.2.1.1 Control systems include automatic and remote control systems.

2.2.1.2 Control systems are to have good control properties. Control systems for the operation of machinery and electrical equipment are to have satisfactory characteristics, i.e., to be stable throughout their operating range so that the operation of the controls will not induce detrimental mechanical or thermal loads. Control systems are also to have necessary accuracy of control.

2.2.1.3 The design of the control system is to be such that a failure in the control system will lead to the least dangerous condition of the controlled process and furthermore, such failure is not to render any reserved automatic or manual control, or both, inoperative.

2.2.1.4 All machinery and electrical installations essential for the safe operation of the ship are, in the case of failure in or out-of-action of any part of automatic or remote control system including failure of power supply, to be capable of:

(1) sending out alarm signals;

(2) replacing immediately faulty component(s) or putting the back-up arrangements into service in time for recovering normal operation (if applicable);

(3) transferring to local manual control, and the transfer of control is not to seriously affect the operating conditions of the machinery and electrical equipment.

2.2.1.5 Control systems for the main propulsion machinery (including main engine and controllable pitch propeller), boilers and electric generating plant are to be independent of each other unless necessary for operation. The control system for each independent propulsion engine is to be provided separately.

2.2.1.6 Where necessary measures are taken to ensure effective monitoring of the partly common equipment in the systems mentioned in 2.1.4.1 above and an alarm is given in case of any failure in such equipment, a partly common use of the equipment may be permitted (see also 2.7.1.4 of this Chapter).

2.2.2 Hydraulic and pneumatic power sources

2.2.2.1 The hydraulic power source and piping of control systems are to comply with the relevant requirements of Chapter 2 and Section 7 of Chapter 4, PART THREE of the Rules, and the following requirements:

(1) The standby hydraulic pump is to start and operate automatically when the discharge pressure from the working pumps falls below a predetermined value and an alarm is to be given.

(2) Where the hydraulic pressure is lower than the required normal working pressure, an alarm is to be given.

2.2.2.2 The pneumatic power source and piping of control systems are to comply with the relevant requirements of Chapter 2, PART THREE of the Rules and the following requirements:

---

① A visual and audible alarm is to be given in the event of a failure of power supply for engine room centralized monitoring and alarm system. For alarms of safety system, alarm system and control system of other equipment in the event of a failure of power supply, refer to Table 3.10.1.1 of Chapter 3 of this PART.

(1) Air vessels for pneumatic controls may be supplied from the main engine starting air vessels or from exclusive air compressors.
(2) Where air vessels are supplied from the exclusive air compressors, at least two compressors are to be provided, one of which is standby, or from one exclusive air compressor and the main air vessel. The air compressors are to start and operate automatically when the air pressure falls below a predetermined value.
(3) Relief valves are to be fitted in the pneumatic control piping, which are to be set to open at a pressure not greater than 1.1 times the normal working pressure.
(4) Reducing valves, filters, oil separators and driers are to be provided in the pneumatic control piping so as to ensure dry, clean and oil-free air to the pneumatic controls. The reducing valves, filters and driers are to be, in general, fitted each in duplicate and in parallel. The provision of a single filter and a single drier may be permitted, provided that means are provided to ensure quick maintenance and renewal of the above-mentioned devices without interrupting the normal operation of the pneumatic control system.

Section 3 SAFETY SYSTEMS

2.3.1 General requirements

2.3.1.1 In case of serious faults endangering the main propulsion engines, boilers, electric generating plants and other essential machinery and electrical equipment, the safety systems are to operate automatically for safeguarding the machinery or electrical equipment in question in the three modes of operation required in 1.1.2.1(5) of this PART and alarms are to be given.
2.3.1.2 When the system has stopped a unit, the unit is not to be restarted automatically before a manual reset has been made.
2.3.1.3 In order to avoid undesirable interruption in the operation of machinery, the system is to intervene sequentially after the operation of alarm system by:
(1) starting of standby units;
(2) load reduction or shutdown, such that the least drastic action is taken first.
2.3.1.4 When the system has been activated, audible and visual alarms are to be given in control station to trace the cause of the safety action.

2.3.2 Means of overriding

2.3.2.1 For the purpose of ensuring the safety of ships, main propulsion machinery systems, such as main diesel engines, steam turbines, gas turbines and electric propulsion systems, are in general to be provided with arrangements for overriding.
2.3.2.2 An indication is to be given and a suitable alarm is to be activated when an overriding action is operated.
2.3.2.3 Means are to be provided to preclude inadvertent operation of the overriding function.

2.3.3 Pneumatic power source and piping

2.3.3.1 The pneumatic power source and piping of safety systems are to be in compliance with the requirements of 2.2.2 of this Chapter, and the pneumatic pipelines are to be as far as practicable separated from the control systems.

Section 4 ALARM SYSTEMS (INCLUDING DISPLAYS)

2.4.1 General requirements

2.4.1.1 All faults of the controlled and monitored machinery or electrical equipment and their control and monitoring systems are to be indicated with alarm signals at the relevant control stations (rooms) so that the engineering personnel on duty are made aware that a machinery fault has occurred.
2.4.1.2 All alarms are to be both audible and visual. According to the nature of faults, the colors used for visual signals are to be, in general, red for vital faults and yellow for general ones. Audible signal is to be of an adequate sound level and to be clearly distinguishable from the fire alarms, telephones and other sound signals (e.g. CO_2 flooding).
2.4.1.3 The alarm system is to be capable of indicating all faults occurred at the same time, and the operation and/or acknowledgement of any alarm is not to inhibit the operation and/or acknowledgement of other alarms occurred at the same time.

2.4.1.4 Arrangements may be fitted to extinguish (silence) audible alarm signals. When alarms are acknowledged and the silencing button is pressed, visual alarm signals are not to be extinguished, but may be altered, for example, from flashing to a steady light, and remain clearly visible. The local silencing of bridge or accommodation alarms is not to stop the audible machinery space alarm. The silencing button for the audible alarms in machinery spaces is permitted to be arranged only in the machinery space or at the engine room centralized control station and the visual alarm signals are to be retained until the fault has been rectified. When the fault has been rectified, the alarm system is to be automatically reset to its normal operating condition.
2.4.1.5 Where a single alarm has been shown in the local control station of engine room, the alarm signal is also to be shown in other relevant remote control stations and may be displayed by means of group alarm.

2.4.2 Inspection and self-monitoring of alarm systems
2.4.2.1 The alarm system is to be designed with self-monitoring properties, i.e., any fault in the alarm system should cause it to detect itself automatically and fall into the alarm (or indication) condition. The extent and depth of self-monitoring is to be determined in connection with the measures taken for maintenance and renewal.
2.4.2.2 The alarm system is to be capable of blockading meaningless signals during certain processes. Manual blockading is to be indicated.

2.4.3 Displays
2.4.3.1 Parameters may be clearly displayed by instrumentation or display units. Parameter displays may be performed separately or selectively, and may be alphanumeric or in the form of graphics or diagrams. But all displays or indications are to be clearly distinguishable. The color of indicating lamps is normally to be green or white. For display units incorporating with computers and the specific requirements for display, IEC 60092-504 Electrical installations in ships - Part 504: Automation, control and instrumentation is to be complied.

Section 5 CONTROL STATIONS (ROOMS)

2.5.1 Arrangement of control stations (rooms)
2.5.1.1 The engine room centralized control station (room) (abbreviated to ISC) is generally to be located within the machinery spaces.
2.5.1.2 The ISC is to be located as far as possible in a position of least vibrations and of low noise level while the ship operates at sea.
2.5.1.3 The ISC within the machinery spaces is to be of the sound-proof construction, with the window glass of the shatter-resistant type. The ISC is to have two means of access located as far remote from each other as practicable, and one of which is to be as far as possible situated near the escape trunk of the machinery spaces or the special purpose escape trunk.
2.5.1.4 The control and monitoring equipment, signal displays, control levers, switches and push buttons within the control stations (rooms) are to be arranged with due attention to thorough ergonomics for the convenience of operation, surveillance, maintenance and the safety of the operators.
2.5.1.5 The local control stations are to comply with the relevant requirements of 1.1.1.5 and 2.5.2 of this PART. It is to be possible for the propulsion machinery to be controlled from a local position even in the case of failure or malfunction in any part of the automatic or remote control systems of any other control station or the propulsion machinery.

2.5.2 Transfer of control
2.5.2.1 Transfer of control between control stations is to be possible to the machinery and electrical equipment under common control from such stations, either when these machinery and electrical equipment are in normal operation or in case of their failures. Such changeover is not to seriously affect the operating conditions of the machinery and electrical equipment.
2.5.2.2 The transfer of control between the ISC and BCS is to be possible only at the ISC, and the transfer of control between the LCS and ISC or BCS is to be possible only at the LCS.
2.5.2.3 Changeover between control stations is to be so arranged that it may be effected only with the acceptance of the station taking control.
2.5.2.4 Provision is to be made at all control stations (rooms) to indicate which station is in control.

2.5.2.5 Where machinery and electrical equipment may be controlled from two or more control stations (rooms), control is to be possible only from one control station at one time. At all control stations, interconnected control positions for the controllers for main propulsion machinery are permitted.
2.5.2.6 Propulsion machinery orders from the navigating bridge are to be indicated at all control positions for the machinery.
2.5.2.7 Where the manual control gear of the main engine or other machinery and electrical equipment is extended directly to the ISC by means of mechanical linkage, the provision of corresponding LCS may be exempted.

2.5.3 Other control stations

2.5.3.1 For the arrangement of other control stations which are in close relation to the safety of machinery and electrical equipment or the safety of the ship, relevant technical information (e.g. arrangement plan, specification of monitoring properties) are to be provided and the relevant requirements of this PART are to be complied with.

Section 6 COMPUTER BASED SYSTEMS

2.6.1 General requirements

2.6.1.1 This Section applies to design, construction, commissioning and maintenance of computer-based systems where they depend on software for the proper achievement of their functions. This Section applies to systems which provide control, alarm, monitoring, safety, or internal vessel communication functions that are subject to classification requirements. This Section does not apply to computer-based systems that are covered by statutory regulations, e.g. loading instruments/ stability computer① and radio communication and navigation equipment covered by SOLAS chapters IV and V.
2.6.1.2 Computer based systems are, in addition to satisfying the requirements of this Section, to satisfy relevant requirements in the Guidelines for Type Approval Test of Electric and Electronic Products and the class notation Cyber Security (P) in the Guidelines for Ship Cyber Security.
2.6.1.3 The following standards may be used for the development of hardware/software of computer based systems:
(1) IEC 61508 Functional safety of electrical/electronic/programmable electronic safety-related systems;
(2) ISO/IEC/IEEE 12207 Systems and software engineering – Software life cycle processes;
(3) ISO 9001 Quality Management Systems – Requirements;
(4) ISO/IEC/IEEE 90003 Software engineering - Guidelines for the application of ISO 9001:2015 to computer software;
(5) IEC 60092-504 Electrical installations in ships - Part 504: Special features - Control and instrumentation;
(6) ISO/IEC 25000 Systems and software engineering - Systems and software Quality Requirements and Evaluation (SQuaRE) - Guide to SQuaRE;
(7) ISO/IEC 25041 Systems and software engineering - Systems and software Quality Requirements and Evaluation (SQuaRE) - Evaluation guide for developers, acquirers and independent evaluators;
(8) IEC 61511 Functional safety - Safety instrumented systems for the process industry sector;
(9) ISO/IEC/IEEE 15288 Systems and software engineering - System life cycle process;
(10) ISO 10007 Quality management – Guidelines for configuration management;
(11) ISO 24060 Ships and marine technology - Ship software logging system for operational technology.
Other standards accepted by ISC may also be considered.

2.6.2 Definitions

2.6.2.1 For the purpose of this Section:
(1) Black-box description: A description of a system's functionality and behaviour and performance as observed from outside the system in question.
(2) Black-box test methods: Verification of the functionality, performance, and robustness of a system, sub-system or component by only manipulating the inputs and observing the outputs. This does not require any knowledge of the system's inner workings and focuses only on the observable behaviour of the system/component under test in order to achieve the desired level of verification.
(3) Computer-based system(CBS): A programmable electronic device, or interoperable set of

① Refer to the requirements of Appendix 1 and Appendix 2 of Chapter 2, PART TWO of the Rules.

programmable electronic devices, organized to achieve one or more specified purposes such as collection, processing, maintenance, use, sharing, dissemination, or disposition of information. CBSs onboard include IT and OT systems. A CBS may be a combination of subsystems connected via network. Onboard CBSs may be connected directly or via public means of communications (e.g. Internet) to ashore CBSs, other vessels' CBSs and/or other facilities.

(4) Failure mode description: A document describing the effects due to failures in the system, not failures in the equipment supported by the system. The following aspects shall be covered:

① list of failures which are subject to assessment, with

② description of the system response to each of the above failures

③ comments to the consequence of each of these failures.

(5) Parameterization: To configure and tune system and software functionality by changing parameters. It does not usually require-computer programming and is normally done by the system supplier or a service provider, not the operator or end-user.

(6) Programmable device: Physical component where software is installed.

(7) Robustness: The ability to respond to abnormal inputs and conditions.

(8) Simulation test: Monitoring, control, or safety system testing where the equipment under control is partly or fully replaced with simulation tools, or where parts of the communication network and lines are replaced with simulation tools.

(9) Software component: A standalone piece of code that provides specific and closely coupled functionality.

(10) Software master files: The computer-files that constitutes the original source of the software. For custom made software this may be readable source- code files, and for COTS software it may be different forms of binary files.

(11) Software-structure: Overview of how the different software components interact and is commonly referred to as the Software Architecture, or Software Hierarchy.

(12) Sub-system: Identifiable part of a system, which may perform a specific function or set of functions.

(13) System: A combination of components, equipment and logic which has a defined purpose, functionality, and performance. In the context of this Section, a specific system is delivered by one system supplier.

(14) System of systems: A system which is made up of several systems In the context of this Section, the system of systems encompasses all monitoring, control and safety systems delivered from the Shipyard as a part of a vessel.

(15) Owner: The organization or person which orders the vessel in the construction phase or the organization which owns or manages the vessel in service. In the context of this Section this is a defined role with specific responsibilities.

(16) Supplier: A generic term used for any organisation or person that is a contracted or a subcontracted provider of services, system components, or software.

(17) Service supplier: A person or company, not employed by an IACS Member, who at the request of an equipment manufacturer, shipyard, vessel's owner or other client acts in connection with inspection work and provides services for a ship or a mobile offshore unit such as measurements, tests or maintenance of safety systems and equipment, the results of which are used by surveyors in making decisions affecting classification or statutory certification and services.

(18) System supplier: An organisation or person that is contracted or a subcontracted provider of system components or software under the coordination of the Systems integrator. In the context of this Section this is a defined role with specific responsibilities.

(19) Systems integrator: Single organization or a person coordinating interaction between suppliers of systems and sub-systems on all stages of life cycle of computer-based systems in order to integrate them into a verified vessel-wide system of systems and to provide proper operation and maintenance of the computer based systems. In the context of this Section this is a defined role with specific responsibilities. During the design and delivery phase the Shipyard is the default Systems integrator, during operations phase the Owner is the default.

(20) Vessel: Ship or offshore unit where the computer-based system is to be installed.

2.6.3 Approval of system and components

2.6.3.1 Computer-based systems that are necessary to accomplish vessel-functions of category II or category III shall be delivered with a vessel-specific Society certificate. The objective of the vessel-specific system certification is to confirm that design and manufacturing of the system has been completed and that the system complies with applicable rules of the classification Society. Vessel-specific system certification consist of two main verification activities:

(1) Assessment of vessel-specific documentation (see documents listed in Table 2.6.4.1(1));
(2) Survey and testing of the system to be delivered to the vessel.
ISC may accept Alternative Certification Scheme (ACS) provided that the requirements are met, and that the system is provided with a vessel-specific certificate.

2.6.3.2 Computer-based systems that are routinely manufactured and include standardized software functions may be type approved in accordance with specified rules of ISC. The type approval consist of two main verification activities:
(1) Assessment of type-specific documentation, including documents listed in Table 2.6.4.1(1) and other documents required to apply for ISC type approval;
(2) Survey and testing of the standardized functions.
Type approval will normally not yield exemption from vessel-specific system certification since vessel-specific functions, parameter configurations and installation elements demand vessel specific verification.

2.6.4 Plans and documents

2.6.4.1 Plans and documents are to be submitted to ISC in accordance with the requirements of Tables 2.6.4.1(1) and 2.6.4.1(2) for computer based systems. Items in Table 2.6.4.1(3) are to be witnessed and surveyed by ISC surveyors.

Plans and documents to be submitted by system supplier **Table 2.6.4.1(1)**

No.	Name of plan	System category

Note: The meanings of symbols used in the Table are as follows:

Ⓐ Submitted to ISC for approval; ① Provided to ISC for information; Ⓦ To be witnessed or surveyed by ISC surveyors.

2.6.5 Structure and category of computer based system

2.6.5.1 The hierarchy and relationships of a typical computer based system are as shown in Figure 2.6.5.1.

Note: Dashed lines show non-developed branches of diagram

Figure 2.6.5.1 Illustrative System Hierarchy

2.6.5.2 The categorization of a system is based on the potential severity of the consequences if the system serving the function fails. Table 2.6.5.2 provides the definitions of the categories.

System categories **Table 2.6.5.2**

Category	Failure effects	Typical System functionality
I	Those systems, failure of which will not lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.	- Monitoring, informational and administrative functions
II	Those systems, failure of which could eventually lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment.	- Vessel alarm, monitoring and control functions which are necessary to maintain the vessel in its normal operational and habitable conditions
III	Those systems, failure of which could immediately lead to dangerous or catastrophic situations for human safety, safety of the vessel and/or threat to the environment.	- Control functions for maintaining the vessel's propulsion and steering - Vessel safety functions

2.6.5.3 Category I systems are normally not subject to verification by ISC, as failure of these systems shall not lead to dangerous situations. However, information pertinent to category I systems shall be required upon request to determine the correct category or ensure that they do not influence the operation of systems in category II and category III. The category of a system shall always be evaluated in the context of the specific vessel in question; thus, the categorization of a system may vary from one vessel to the next. This means that the examples of categories below are given as guidance only, the systems are not exhaustive.

(1) Category I systems:

① Fuel monitoring system;

② Maintenance support system;

③ Diagnostics and troubleshooting system;
④ Closed circuit television;
⑤ Cabin security, entertainment system;
⑥ Fish detection system.

(2) Category II systems:
① Fuel oil treatment system;
② Alarm monitoring and safety systems for propulsion and auxiliary machinery;
③ Inert gas system;
④ Control, monitoring and safety system for cargo containment system;
⑤ Monitoring and safety system.

(3) Category III systems:
① Propulsion control system;
② Steering gear control system;
③ Electric power system (including power management system);
④ Dynamic positioning system (DP 2 and DP 3).

2.6.6 Requirements on development and certification of computer-based system

2.6.6.1 A global top-down approach shall be undertaken in the design and development of both hardware and software and the integration in sub-systems, systems, and system of systems, spanning the complete system lifecycle. This approach shall be based on the standards as listed herein or other standards recognized by ISC.

2.6.6.2 Systems integrators and system suppliers shall, in the development of computer-based systems for category II and category III, comply to a recognised quality standard such as ISO 9001; also incorporating principles of IEC/ISO 90003. The quality system is certified as compliant to a recognized standard by an organisation with accreditation under a national accreditation scheme or ISC confirms compliance to a standard through a specific assessment of the quality system. The quality system shall as a minimum include the following topics in Table 2.6.6.2:

Quality system **Table 2.6.6.2**

Area		Role	
No.	Topic	System supplier	System integrator
1	Responsibilities and competency of the staff	x	x
2	The complete lifecycle of delivered software and of associated hardware	x	x
3	Specific procedure for unique identification of a computer-based system, its components and versions	x	
4	Creation and update of the vessel's system architecture		x
5	Organization set in place for acquisition of software and related hardware from suppliers	x	x
6	Organization set in place for software code writing and verification	x	
7	Organization set in place for system validation before integration in the vessel	x	
8	Specific procedure for conducting and approving of systems at FAT and SAT	x	x
9	Creation and update of system documentation	x	
10	Specific procedure for software modification and installation on board the vessel, including interactions with shipyard and owner	x	x
11	Specific procedures for verification of software code	x	
12	Procedures for integrating systems with other systems and testing of the system of systems for the vessel	x	x
13	Procedures for managing changes to software and configurations before FAT	x	
14	Procedures for managing and documenting changes to software and configurations after FAT	x	x
15	Checkpoints for the organization's own follow-up of adherence to the quality system	x	x

2.6.7 Requirements on the system supplier

2.6.7.1 The system supplier shall define a quality plan (No.1 in Table 2.6.4.1(1)) and document that the quality management system is applied for the design, construction, delivery, and maintenance of the specific system to be delivered. All applicable items described in Table 2.6.6.2 (for the system supplier role) shall be demonstrated to exist and being followed, as relevant.

2.6.7.2 A method for unique identification of a system, its different software components and different revisions of the same software component shall be applied. The method shall be applied throughout the lifecycle of the system and the software. The documentation of the method is typically a part of the quality management system. Technical requirements for unique identification of systems and software are given in 2.6.11.1 of this Section.

2.6.7.3 The system's specification and design shall be determined and documented in a system description (No.2 in Table 2.6.4.1(1)). In addition to serve as a specification for the detailed design and implementation, the purpose of the system description is to document that the entire system-delivery is according to the specifications and in compliance with applicable rules and regulations. The system description shall contain information of the following:

(1) Purpose and main functions, including any safety aspects;
(2) System category as defined;
(3) Key performance characteristics;
(4) Compliance with the technical requirements and ISC rules;
(5) User interfaces/mimics;
(6) Communication and Interface aspects: Identification and description of interfaces to other vessel systems;
(7) Hardware-arrangement related aspects:

① Network-architecture/topology, including all network components like switches, routers, gateways, firewalls etc.;
② Internal structure with regards to all interfaces and hardware nodes in the system (e.g. operator stations, displays, computers, programmable devices, sensors, actuators, I/O modules etc.);
③ I/O allocation (mapping of field devices to channel, communication link, hardware unit, logic function);
④ Power supply arrangement;
⑤ Failure mode description.

2.6.7.4 Evidence of environmental type testing (No.3 in Table 2.6.4.1(1)) according to ISC Guidelines for Type Approval Test of Electric and Electronic Products regarding hardware elements included in the system and sub-systems shall be submitted to ISC.

2.6.7.5 The software created, changed, or configured for the delivery project shall be developed and have the quality assurance activities assessed according to the selected standard(s) as described in the quality plan. The quality assurance activities may be performed on several levels of the software -structure and shall include both custom-made software and configured components (e.g. software libraries) as appropriate. For components in systems of Category II and III, the scope, purpose, and results of all performed reviews, analyses, tests, and other verification activities shall be documented in test reports (No.4 in Table 2.6.4.1(1)). The verification of the software shall as a minimum verify the following aspects based on black-box methods[①]:

(1) Correctness, completeness and consistency of any parameterization and configuration of software components;
(2) Intended functionality;
(3) Intended robustness.

2.6.7.6 The system shall as far as practicable be tested before the FAT. The main purpose of the system test is for the system supplier to verify that the entire system delivery is according to the specifications, approved documentation and in compliance with applicable rules and regulations; and further, that the system is completed and ready for the FAT. Faults are to be simulated as realistically as possible to demonstrate appropriate system fault detection and system response. Some of the testing may be performed by utilizing simulators and replica hardware. The test-environment shall be documented, including a description of any simulators, emulators, test-stubs, test-management tools, or other tools affecting the test environment and its limitations. Test cases and test results shall be documented in test programs and test reports (No.5 in Table 2.6.4.1(1)) respectively. The testing shall at least verify the following aspects of the

---

① Some of the methods utilized in this activity are sometimes referred to as "software unit test" or "developer test" and may also include verification methods like code-reviews and static- or dynamic code analysis.

system:
(1) Functionality;
(2) Effect of faults and failures (including diagnostic functions, detection, alerts response);
(3) Performance;
(4) Integration between software and hardware components;
(5) Human-machine interfaces;
(6) Interfaces to other systems.

2.6.7.7 A factory acceptance test (FAT) shall be arranged for the system in question. The main purpose of the FAT is to demonstrate to ISC that the system is completed and compliant with applicable classification rules, thus enabling issuance of a Society Certificate for the system. The FAT test program (No.6 in Table 2.6.4.1(1)) shall cover a representative selection of the test items from the internal system test (described in 2.6.7.6 of this Section), including normal system functionality and response to failures. For category II and III systems, network testing to verify the network resilience requirements in 2.6.11.2 of this Section shall be performed. If agreed by all parties, the network testing may be performed as a part of the system test onboard the vessel. The FAT shall as a rule be performed with the project specific software operating on the actual hardware components to be installed on board, with necessary means for simulation of functions and failure responses, however other solutions such as replica hardware or simulated hardware (emulators) may be agreed with ISC. For each test-case it shall be noted if the test passed or failed, and the test-results shall be documented in a test report (No.7 in Table 2.6.4.1(1)). The test report shall also contain a list of the software (including software versions) that were installed in the system when the test was executed[①].

2.6.7.8 The initial installation and subsequent updates of the software components of the system shall be done according to a management of change procedure which has been agreed between the system supplier and the systems integrator. The management of change procedure shall comply with the requirements in 2.6.10 of this Section. Cyber security measures shall be observed as described in ISC Guidelines for Ship Cyber Security.

2.6.8 Requirements on the systems integrator

2.6.8.1 For the purposes of this Section, the Shipyard is considered as the systems integrator in the development and delivery phase unless another organization or person is explicitly appointed by the Shipyard.

2.6.8.2 The systems integrator shall define a quality plan (No.1 in Table 2.6.4.2(1)) and document that the quality management system is applied for the installation, integration, completion, and maintenance of the systems to be installed on board. All applicable items described in Table 2.6.6.2 (for the systems integrator role) shall be demonstrated to exist and being followed, as relevant.

2.6.8.3 For each system delivery to a particular vessel, it shall be decided which category the system falls under based on the failure effects of the system (as defined in 2.6.5.2 of this Section). The category for a specific system must be conveyed to the relevant system supplier. ISC may decide that a risk-assessment[②] (No.3 in Table 2.6.4.1(2)) is needed to verify the proper system category.

2.6.8.4 The system of systems (SoS) shall be specified and documented (No.4 in Table 2.6.4.1(2)). This architecture specification provides the basis for category determination and development of the different integrated systems by allocating functionality to individual systems and by identifying the main interfaces between the systems[③]. It shall also serve as a basis for the testing of the integrated systems on the vessel level (see 2.6.8.6 of this Section).

The vessel's system architecture shall at least contain description of:
(1)Overview of the total systems architecture (the system of systems);
(2)Each system's purpose and main functionality;
(3)Communication and interface aspects between different systems.

2.6.8.5 A system acceptance test shall be arranged onboard the vessel. The main purpose of the system acceptance test (SAT) is to verify the system functionality, after installation and integration with the applicable machinery/electrical/process systems on board including possible interfaces with other control and monitoring systems. For each test-case it shall be noted if the test passed or failed, and the test-results shall be documented in a test report (No.6 in Table 2.6.4.1(2)). The test report shall also contain a list of the

---

① For complex systems there may be a large difference in scope between the "Internal system testing before FAT" activity and the FAT, while for some systems the scope may be identical.

② IEC/ISO31010 "Risk management - Risk assessment techniques" may be used as guidance in order to determine method of risk assessment.

③ See network topology in ISC Guidelines for Ship Cyber Security.

software (including software versions) that were installed in the system when the test was executed.

2.6.8.6 Integration tests shall be conducted after installation and integration of the different systems in its final environment on board[①]. The purpose of the tests is to verify the functionality of the complete installation (system of systems) including all interfaces and inter-dependencies in compliance with requirements and specifications. The testing shall at least verify the following aspects of the system of systems:

(1) The overall functionality of the interacting systems as a whole;
(2) Failure response between systems;
(3) Performance;
(4) Human-machine interfaces;
(5) Interfaces between the different systems.

2.6.8.7 The systems integrator shall follow procedures for management of change (No.9 in Table 2.6.4.1(2)) to the system as described in 2.6.10 of this Section.

2.6.9 Requirements on maintenance of computer-based systems

2.6.9.1 For the purposes of this Section, the vessel owner is considered to be the systems integrator in the operations phase unless another organization or person is explicitly appointed by the owner. Accordingly, ISC shall in a timely manner be informed by the owner about the appointed systems integrator which is responsible for implementing any changes to the systems in conjunction with system supplier(s).

2.6.9.2 The systems integrator shall ensure that necessary procedures for software and hardware change management exist on board, and that any software modification/upgrade are performed according to the procedure(s). For details about change management please see paragraph 2.6.10 of this Section.

2.6.9.3 Changes to computer-based systems in the operational phase shall be recorded. The records shall contain information about the relevant software versions and other relevant information as described in 2.6.10.9 of this Section.

2.6.9.4 The system supplier shall follow procedures for maintenance of the system including procedures for management of change as described in 2.6.10 of this Section.

2.6.9.5 The system supplier shall make sure that the planned changes to a system have passed relevant in-house tests before the change is made to systems on board.

2.6.10 Management of change

2.6.10.1 The management of change process shall be coordinated and agreed between the relevant stakeholders along the different stages of the lifecycle of the computer-based system[②]. If changes are required to a system after it has been approved by applicable stakeholders (typically the systems integrator and ISC at FAT) the modifications shall follow defined change management procedures.

2.6.10.2 The change management procedures cover both hardware and software. After FAT, the system supplier shall manage all changes to the system in accordance with the procedure. Examples could be qualification of new versions of acquired software, new hardware, modified control logic, changes to configurable parameters. The procedure(s) shall at least describe the activities listed in 2.6.10.3 to 2.6.10.10 of this Section.

2.6.10.3 The system supplier shall make sure that each system and software version is uniquely identifiable, see 2.6.7.2 of this Section.

2.6.10.4 There shall be defined mechanisms for handling of the files that constitutes the master-files for a software component. Personnel authorities shall be clearly defined along with the tools and mechanisms used to ensure the integrity of the master files.

2.6.10.5 It shall be clearly defined how to perform backup and restoration of the software components of a computer-based system onboard the vessel.

2.6.10.6 Before a change to the system is made, an impact analysis shall be performed in order to determine to what extent the change activities shall be performed. The analysis shall:

(1) Determine the criticality of the change.
(2) Determine the impact on existing documentation.

---

① For complex systems there may be a large difference in scope between the "System acceptance test (SAT) onboard the vessel" activity and the SOST, while for some systems the scope may be overlapping or identical. It is possible to combine the two activities into one when the test scope is similar.

② Typically, the management of change address at least three different stages: Development and internal verification before FAT, involving the system supplier and sub-suppliers; From FAT to handover of the vessel to the owner, involving the system supplier, the systems integrator, ISC, and the owner; In operation, involving the system supplier, service suppliers, the owner, and ISC.

(3) Determine the needed verification and test activities.
(4) Determine the need to inform other stakeholders about the change.
(5) Determine the need to obtain approval from other stakeholders (e.g. ISC and or Owner) before the change is made.
2.6.10.7 When maintenance includes installation of new versions of the software in the system, it shall be possible to perform a rollback of the software to the previous installed version with the purpose of returning the system to a known, stable state. Roll-backs shall be documented and analysed to find and eliminate the root cause.
2.6.10.8 To the largest degree practically possible, modifications shall be verified before being installed onboard. After installation, the modification(s) shall be verified onboard according to a documented verification program containing:
(1) Verification that the new functionalities and/or improvements have had the intended effect.
(2) Regression test to verify that the modification has not had any negative effects on functionality or capabilities that was not expected to be affected.
2.6.10.9 Changes to systems and software shall be documented in change records to allow for visibility and traceability of the changes. The change records shall contain at least the following items:
(1) The purpose for a change;
(2) A description of the changes and modifications;
(3) The main conclusions from the impact analysis (see 2.6.10.6 of this Section);
(4) The identity and version of any new system or software version(s) (see 2.6.10.3 of this Section);
(5) Test reports or tests summaries (see 2.6.10.8 of this Section).
2.6.10.10 Documentation of the changes to software may be recorded in the planned maintenance system (PMS), in a software registry or equivalent.
2.6.10.11 During in operation (vessel in service) phase, the verification by ISC regarding the management of change in operation is generally performed during the annual survey of the vessel. Procedures for management of change and relevant change records shall be made available at the time of survey. In the cases where the change requires approval from ISC up front, the relevant procedures and documentation for the change in question may be verified at that time. During newbuilding, the verification of management of change in the newbuilding phase is divided into two:
(1) Procedures are verified as a part of the verification of the quality management system (Table 2.6.6.2);
(2) Project specific implementation of the procedures are verified during FAT and after FAT.

2.6.11 Technical requirements on computer-based systems
2.6.11.1 The system shall provide means to identify its name, version, identifier, and manufacturer. It is recommended that the system can automatically report the status of its software to a ship software logging system (SSLS) as specified in the international standard ISO 24060.
2.6.11.2 Loss of a data link shall be specifically addressed in risk assessment analysis/FMEA, including:
(1) A single failure in data link shall not cause loss of vessel- functions of category III. Any effect of such failures shall meet the principle of fail-to-safe for the vesselfunction(s) being served.
(2) For vessel-functions of category II and III, any loss of functionality in the remote control system shall be compensated for by local/manual means.
(3) The data link shall have means to prevent or cope with excessive communication rates.
(4) Data links shall be self-checking, detecting failures or performance issues on the link itself and data communication failures on nodes connected to the link.
(5) Detected failures shall initiate an alarm.
2.6.11.3 Category III systems shall not use wireless data links unless specifically considered by ISC on the basis of an engineering analysis carried out in accordance with an International or National Standard acceptable to ISC.
2.6.11.4 Other categories of systems may use wireless data links with the following requirements:
(1) Recognised international wireless communication system protocols shall be employed, incorporating:
① Message integrity. Fault prevention, detection, diagnosis, and correction so that the received message is not corrupted or altered when compared to the transmitted message.
② Configuration and device authentication. Shall only permit connection of devices that are included in the system design.
③ Message encryption. Protection of the confidentiality and or criticality of the data content.
④ Security management. Protection of network assets, prevention of unauthorized access to network assets.
(2) The internal wireless system within the vessel shall comply with the radio frequency and power level

requirements of International Telecommunication Union and flag state requirements.
(3) Consideration should be given to system operation in the event of port state and local regulations that pertain to the use of radio-frequency transmission prohibiting the operation of a wireless data communication link due to frequency and power level restrictions.
(4) For wireless data communication equipment, tests during harbour and sea trials are to be conducted to demonstrate that radio-frequency transmission does not cause failure of any equipment and does not self-fail as a result of electromagnetic interference during expected operating conditions.
2.6.11.5 The implementation of the technical requirements provided in 2.6.11 of this Section is verified as part of the system description, FAT and SAT described above.

Section 7 SENSORS

2.7.1 General requirements

2.7.1.1 The sensors are to give stable and normal operational performance over a long period of time. The measuring range and frequency characteristics (if applicable) of sensors are to be consistent with the expected maximum variation range and variation of velocity of the parameters being detected. The sensors are to possess suitable accuracy and sensitivity.
2.7.1.2 The sensors are to have good compatibility with the environmental conditions at their positions. The sensors are to be mechanically robust and durable, having good mechanical protection, reliable electrical connections and good insulated property.
2.7.1.3 The sensors are to be so sited that they can properly reflect the monitored parameters and are readily accessible for testing and renewal. In order that maintenance and renewal can be carried out easily, a protective cover is to be fitted for sensors. Where the sensors are sited in positions inaccessible for renewal, a standby sensor is to be fitted.
2.7.1.4 An independent sensor is to be provided for Mode a protective action; if not specially required, for Mode b protective action, the use of a common sensor with display and alarm is permitted; for Mode c protective action, the use of a common sensor with alarm is permitted.

Section 8 MAIN PROPULSION MACHINERY REMOTELY CONTROLLED FROM NAVIGATION BRIDGE

2.8.1 General requirements

2.8.1.1 If main propulsion machinery is remotely controlled from navigation bridge, the requirements of 2.8.1.2 to 2.8.1.12 of this Chapter are to be complied with.
2.8.1.2 Under all sailing conditions, including manoeuvring, the speed and direction of main propulsion machinery and, if applicable, pitch of the propeller are to be fully controllable from the navigating bridge.
2.8.1.3 The remote control of main propulsion machinery from navigation bridge is to be performed by a single control device for each independent propeller, with automatic performance of all associated services including, where necessary, means of preventing overload and prolonged running in critical speed ranges of the propelling machinery. Where multiple propellers are designed to operate simultaneously, they may be controlled by one control device.
2.8.1.4 The bridge control system is to be independent from the other transmission system, however, one control lever for both system may be accepted.
2.8.1.5 Operations following any setting of the bridge control device including reversing from the maximum ahead service speed in case of emergency are to take place in an automatic sequence and with time intervals acceptable to the machinery.
2.8.1.6 The main propulsion machinery is to be provided with an emergency stopping device on the navigating bridge and independent from the bridge control system, but its actuating unit may not be independent and the arrangement of which is to be such as to preclude inadvertent operation.
2.8.1.7 Main propulsion machinery orders from the navigation bridge are to be indicated in the engine room centralized control station (if fitted) or at the main propulsion machinery local control station.
2.8.1.8 Remote starting of the propulsion machinery is to be automatically inhibited if conditions exist which may hazard the machinery, e.g. shaft turning gear engaged, drop of lubricating oil pressure.
2.8.1.9 The design of the bridge control system is to be such that in case of its failure, an alarm is given. In this case, the speed and direction of the propeller thrust is to be maintained until local control is in

operation, unless this is considered impracticable. In particular, lack of power (electric, pneumatic, hydraulic) is not to lead to major and sudden change in propulsion power or direction of propeller rotation.

2.8.1.10 An alarm is to be provided on the navigation bridge and in the machinery space to indicate low starting air pressure which is to be set at a level to permit further main propulsion machinery starting operations. If the remote control system of the main propulsion machinery is designed for automatic starting, the number of automatic consecutive is to be limited to not more than 3. Visual and audible alarms are to be given on the navigation bridge at the third failure.

2.8.1.11 Bridge control station is to indicate:

(1) main engine speed or propeller speed;

(2) the direction of rotation of fixed pitch propellers or the blade angle (or the pitch) for controllable pitch propellers;

(3) clutch position and shaft brake position (where applicable);

(4) the control station in control;

(5) the power supply to control and monitoring systems relating to the bridge control station.

2.8.1.12 If main propulsion machinery is remotely controlled from navigation bridge, automation systems are to be designed in a manner which ensures that threshold warning of impending or imminent shutdown or shutdown of the main propulsion machinery is given to the officer in charge of the navigational watch in time to assess navigational circumstances in an emergency. In particular, the systems are to control, monitor, report, alert and take safety action to slow down or stop propulsion while providing the officer in charge of the navigational watch an opportunity to manually intervene (such as overriding), except for those cases where manual intervention will result in total failure of the engine and/or main propulsion machinery within a short time, for example in the case of overspeed.

CHAPTER 3 REQUIREMENTS FOR CLASS NOTATION AUT-0 OF PERIODICALLY UNATTENDED MACHINERY SPACES

Section 1 GENERAL PROVISIONS

3.1.1 Application

3.1.1.1 This Chapter applies to ships of which the main propulsion machinery is remotely controlled from the BCS and the machinery space including ISC is periodically unattended. In this connection, the class notation is AUT-0.

3.1.1.2 Ships with the class notation AUT-0 are, in addition to complying with the requirements of this Chapter, to be in compliance with the requirements of Chapters 1 and 2 of this PART.

3.1.1.3 For passenger ships with the class notation AUT-0, attention is to be paid to the requirements of the flag Administration, if any.

3.1.1.4 In the unattended period, automated systems are to ensure the normal continuous operation of the following machinery and electrical equipment:

(1) main propulsion machinery, including main engines (such as main diesel engine, main steam turbine, main gas turbine and electric propulsion installations), gearing (including clutches and reduction gearboxes) and propellers (including controllable pitch propellers);

(2) essential auxiliary machinery serving the main propulsion machinery;

(3) main and auxiliary boilers;

(4) electric generating plant;

(5) other machinery and electrical equipment, such as air compressors, bilge systems (including oily water separators), valves associated with remote control, fuel oil systems as well as others of which automated control and monitoring is deemed necessary by ISC.

Section 2 MAIN PROPULSION MACHINERY

3.2.1 General requirements

3.2.1.1 The starting, speed regulating, reversing (including shaft reversing) and stopping of the main propulsion machinery are to be capable of being remotely controlled or automatically, sequentially controlled from the ISC. In the case of failure of any part of the control systems, it is to be possible for the main propulsion machinery to be manually controlled from the LCS with regard to the above-mentioned operations.

3.2.2 Main diesel engines

3.2.2.1 The main diesel engines are to comply with the relevant requirements of Chapter 9, PART THREE of the Rules.

3.2.2.2 The control systems of main diesel engines are to comply with the following requirements:

(1) The control system is to ensure that under all operational conditions the engines and shafting will not be subjected to detrimental mechanical and thermal overloads.

(2) The automatic sequential control of main diesel engines is to be provided with necessary interlocks so as to prevent any mechanical damage.

(3) The number of unsuccessful automatic consecutive starts of main diesel engines is not to be more than 3. The main engine is to stop starting at the third failure, and an audible and visual alarm is to be given and the single alarm is to be extended to the BCS.

(4) The control system of main diesel engines is to be so designed that a critical speed range will be automatically crossed over promptly.

(5) Where the main diesel engine is used for main propulsion, means are to be provided to keep the starting air pressure within the required pressure range.

3.2.2.3 The safety system of main diesel engines is to comply with the following:

(1) Safeguards

① A suitable alarm is to be activated at the starting of standby pumps for which the automatic starting is required.

② If an overriding function of the required automatic reduction of power is provided, means are to be provided to preclude inadvertent operation of the overriding function, and a suitable alarm is to be

activated by the operation.

③ If an overriding function of the required automatic stops is provided (with the exception of overspeed), means are to be provided to preclude inadvertent operation of the overriding function, and a suitable alarm is to be activated by the operation. When the main engine is stopped automatically, restarting after restoration of normal operating conditions is to be possible only after manual reset, e.g. by-passing the control lever through the 'stop' position. Otherwise, automatic restarting is not permissible.

(2) For the requirements for the safety system of main diesel engines, refer to column 4 of Table 3.10.1.1 of this Chapter.

(3) In addition, emergency shutdown devices are to be provided at the BCS and ISC (see also 2.8.1.6 of this PART and 3.7.3.5 of this Chapter).

3.2.2.4 The alarm system (including displays) of main diesel engines is to satisfy the following requirements:

(1) Remote indications required in Table 3.10.1.1 of this Chapter are only for items to be displayed and alarmed at the ISC, see columns 2 and 3 of that Table.

(2) For items to be alarmed and the mode of alarms at the BCS, refer to column 5 of Table 3.10.1.1 of this Chapter. The items to be displayed are specified in 2.8.1.11, Chapter 2 of this PART.

3.2.2.5 Where vibration dampers are fitted for main engines:

For torsional or axial vibration dampers oiled by circulating lubrication from main engines and based on amortization thereof, the requirements for the items to be automatically controlled and monitored are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

3.2.3 Main steam turbines

3.2.3.1 The main steam turbines are to comply with the relevant requirements of Chapter 7, PART THREE of the Rules.

3.2.3.2 The control system of main steam turbines is to comply with the following requirements.

(1) Means are to be provided, by automatic steam spinning, to prevent the risk of thermal distortion of the main steam turbine, when the shaft has been stopped for a period exceeding the predetermined time in the maneuvering mode. However, device capable of stopping such automatic spinning is to be provided in the bridge.

(2) The control system is to be so designed that a critical speed range will be automatically crossed over promptly. Or alternatively, audible and visual alarms are to be given automatically when the turbine is running in the critical speed range, so as to warn the man-on-watch to cross over the critical speed range by manual control.

3.2.3.3 For the requirements for the safety system of main steam turbines, refer to column 4 of Table 3.10.1.1 of this Chapter.

3.2.3.4 The alarm system (including displays) of main steam turbines is to comply with the following requirements.

(1) For items to be displayed and alarmed at the ISC, refer to columns 2 and 3 of Table 3.10.1.1 of this Chapter.

(2) For items to be alarmed and the mode of alarms at the BCS, refer to column 5 of Table 3.10.1.1 of this Chapter. The items to be displayed are specified in 2.8.1.11, Chapter 2 of this PART.

3.2.4 Main gas turbines

3.2.4.1 The main gas turbines are to comply with the relevant requirements of Chapter 8, PART THREE of the Rules.

3.2.4.2 The control system of main gas turbines is to comply with the following requirements.

(1) When the gas turbine increases power from starting to rated condition or decreases power from rated condition to stop running, provision is to be made so that dangerous thermal and/or mechanical stresses will not occur in any part of the turbine due to the control of oil fuel supply, except in case of emergency control. Gas turbine remote control systems are to be so designed that the turbine exhaust gas temperature and the rotor speed can be maintained within a predetermined range and that the combustion in combustion chamber can be maintained in a steady state under normal operations.

(2) The remote control system of gas turbines is to be so designed that the lubricating oil system, oil fuel system and cooling system are interlocked as appropriate in order that the starting and stop of gas turbine operation can be carried out according to the predetermined procedure with sequential control complying with the following requirements:

① the lubricating oil pumps are to be kept in operation both before starting and after stopping the gas turbine. However, special consideration may be given to gas turbines fitted with roller bearings and attached lubricating oil pumps;

② the combustion chambers are to be sufficiently purged with air before ignition;

③ main oil fuel valves are not to open prior to ignition spark;

④ the ignition of each burner is not to exceed the predetermined duration. And if the gas turbine cannot achieve starting within the predetermined period, it is not to repeat the starting;

⑤ no excessive fuel is to be supplied into the combustion chamber during ignition.

(3) The remote control system for single-screw multi-turbine unit is to be so designed that the load on each turbine will not be abnormally distributed.

3.2.4.3 For the requirements for the safety system of main gas turbines, refer to column 4 of Table 3.10.1.1 of this Chapter.

3.2.4.4 The alarm system (including displays) of main gas turbines is to comply with the following requirements:

(1) For items to be displayed and alarmed at the ISC, refer to columns 2 and 3 of Table 3.10.1.1 of this Chapter.

(2) For items to be alarmed and the mode of alarms at the BCS, refer to column 5 of Table 3.10.1.1 of this Chapter. The items to be displayed are specified in 2.8.1.11, Chapter 2 of this PART.

3.2.5 Controllable pitch propellers

3.2.5.1 Controllable pitch propellers are to comply with the relevant requirements in Section 3, Chapter 11, PART THREE of the Rules.

3.2.5.2 Blade angle (or pitch) is to be capable of being remotely controlled or automatically, sequentially controlled from the BCS.

3.2.5.3 The remote control is to be performed by a single control device for each independent propeller, with automatic performance of all associated services. The control of a multi-propeller system where the propellers will possibly be in operation simultaneously may be performed by one device.

3.2.5.4 The combined control system of main engines and controllable pitch propeller for main propulsion is to be capable of preventing the engines and shafting from being overloaded and stopped due to overloading or overspeed.

3.2.5.5 For the hydraulic remote control system of controllable pitch propellers for main propulsion, a standby power source is to be provided. The standby pump supplying hydraulic power for pitch control is to be capable of automatically starting when the pressure of the hydraulic system is below the predetermined value.

3.2.5.6 The blade angle (or pitch) and shaft speed of controllable pitch propellers is to be indicated at each control station from which it is possible to control the propeller pitch (see 2.8.1.11, Chapter 2 and Table 3.10.1.1 of this PART).

3.2.5.7 For the items to be alarmed with regard to controllable pitch propellers, refer to Table 3.10.1.1 of this Chapter.

3.2.6 Electric propulsion installations

3.2.6.1 The function of control and monitoring of the electric propulsion installations is to comply with the requirements in Section 2, Chapter 15, PART EIGHT of the Rules.

3.2.6.2 The electric propulsion installations are to be capable of being controlled at the BCS, and there are to be provided with instruments for indicating the direction of rotation and speed of the propeller shaft, as well as those for indicating other necessary operational parameters.

3.2.7 Clutches

3.2.7.1 The requirements for the items to be automatically controlled and monitored for clutches are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

3.2.8 Gearboxes

3.2.8.1 The requirements for items to be automatically controlled and monitored for gearboxes are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

Section 3 BOILERS

3.3.1 Main boilers

3.3.1.1 The main boilers are to comply with the relevant requirements of Chapter 6, PART THREE of the Rules.

3.3.1.2 The control system of main boilers is to comply with the following requirements.

(1) Water level control

① The automatic control system is to ensure that the boiler water level is maintained within the predetermined range under all working conditions.

② Each boiler is to be provided with two independent low-water-level sensors (one of which is used in the safety system to detect the limited low water level) and one high-water-level sensor. Water level sensors are to be so located as to prevent the release of malfunction signals due to the rolling and pitching of the ship.

(2) Combustion control

① The automatic combustion control system is to be capable of maintaining the predetermined amount of steam generation, steam pressure, steam temperature and a stable combustion of the main steam turbine under all working conditions.

② The sequentially controlled boilers with an automatic ignition system are to satisfy the following requirements:

(a) prior to the initial ignition of the burner, the combustion chamber and flue passes are to be prepurged. The purging time is to be appropriate to a minimum of four air changes in the combustion chamber and flue passes. During boiler purge, the air registers and dampers are to be kept widely open;

(b) ignition can only be initiated after the air entry into and on completion of prepurging of the combustion chamber. The burner fuel valves are not to open prior to ignition spark. In the event of ignition failure, the ignition devices and burner fuel supply valves are to be automatically shut off. The time from fuel supply valve opening to closing is not to be greater than 15 s;

(c) each burner is to be fitted with a flame scanner designed to automatically shut off the fuel oil supply valve in the event of flame failure, and the action of shutoff is to be capable of closing the valve within 6 s following the flameout.

3.3.1.3 The safety system of main boilers:

(1) Where any one of the following faults takes place, the boiler fuel oil supply is to be automatically shut off, or alternatively, equivalent means are to be adopted for the emergency shutdown of the boiler:

① flame failure (i.e. flameout on all burners) in the combustion chamber or ignition failure;

② the water level in the boiler is below the limited low water level (the limited low water level is not to be lower than the lowest permissible water level or the level visible in the gauge glass);

③ loss of the pressure of combustion air in the forced draft to boiler.

(2) In addition to those mentioned in (1) above, separate emergency manual shutoff devices for each boiler fuel oil supply are to be provided at ISC (see also 3.7.3.5 of this Chapter).

(3) The standby pumps for boiler fuel oil are to start automatically when the discharge pressure from the working pumps falls below a predetermined value.

(4) The standby pumps for boiler feed water are to start automatically when the pressure or flow rate from the working pumps falls below a predetermined value.

3.3.1.4 The alarm system of main boilers (including displays)

(1) The items to be displayed and alarmed at the ISC are indicated in columns 2 and 3 of Table 3.10.1.1 of this Chapter.

(2) The items to be alarmed and the mode of alarms at the BCS are indicated in column 5 of Table 3.10.1.1 of this Chapter.

3.3.2 Auxiliary boilers

3.3.2.1 Auxiliary boilers are to comply with the relevant requirements of Chapter 6, PART THREE of the Rules.

3.3.2.2 The combustion control of auxiliary boilers is in general to comply with the requirements of 3.3.1.2(2) of this Section.

3.3.2.3 The safety system of auxiliary boilers is to comply with the requirements of 3.3.1.3(1), 3.3.1.3(2) and 3.3.1.3(3) of this Section. And the standby pumps for boiler feed water are to be started and put into service automatically in case the water level in the boiler is lower than the predetermined value.

3.3.2.4 The items to be automatically controlled and monitored for auxiliary boilers are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

3.3.3 Exhaust gas boilers

3.3.3.1 Exhaust gas boilers are to comply with the relevant requirements of Chapter 6, PART THREE of the Rules.
3.3.3.2 The items to be automatically controlled and monitored for exhaust gas boilers are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.
3.3.3.3 Indicating lights for the operation of boiler water pumps are to be provided at the ISC.
3.3.3.4 It is to be ensured that the safety system of exhaust gas boilers is capable of starting the action of by-pass of exhaust gas or the mechanism of vapour release in case steam drum outlet pressure/temperature of steam boilers is excessively high.

3.3.4 Thermal oil heaters

3.3.4.1 The thermal oil heaters are to comply with the relevant requirements in Section 8, Chapter 4, PART THREE of the Rules.
3.3.4.2 The items to be automatically controlled and monitored for thermal oil heaters are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.
3.3.4.3 The standby pumps are to be started automatically when outlet pressure of circulating pumps for transfer of fuel oil is lower than the predetermined value.
3.3.4.4 For ensuring stable working conditions throughout the operating range of the heater, automatic control is to be provided for the following:
(1) combustion system;
(2) temperature or viscosity of fuel oil (only for heavy oil);
(3) temperature of thermal oil.

Section 4 ELECTRIC GENERATING PLANT

3.4.1 General requirements

3.4.1.1 In addition to complying with the requirements of this Section, the electric generating plant is to be in compliance with the relevant requirements of Chapter 2, PART FOUR of the Rules.
3.4.1.2 The items to be automatically controlled and monitored for electric generating plant are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

3.4.2 Continuity of power supply

3.4.2.1 Where electrical power is normally supplied by one generating set, arrangements, such as load shedding referred to in 3.4.2.6 of this Section or automatic starting of a standby generating set, etc. are to be provided to ensure that the safety of the ship under all sailing conditions, including maneuvering, is at least equivalent to that of a ship having the machinery space manned.
3.4.2.2 If the electrical power is normally supplied by more than one generator operating in parallel, provision is to be made by means such as load shedding referred to in 3.4.2.6 of this Section, or by appropriate separation of the switchboard bus-bars to ensure that, in the event of loss of one of the generating sets, the remaining set(s) are kept in operation without overload to permit propulsion and steering, and to ensure the safety of the ship.
3.4.2.3 In the event of a failure of the generating set in service, a standby generating set is to be capable of automatically starting and connecting to the main switchboard, with a sufficient capacity to supply those services necessary to ensure that the safety of the ship under all sailing conditions, including maneuvering, is at least equivalent to that of a ship having the machinery spaces manned.
3.4.2.4 All motor-driven essential auxiliaries serving the main propulsion machinery are to be capable of automatically re-starting in a sequence upon restoration of power after interruption.
3.4.2.5 The automatic starting system and characteristics of the standby generating set are to be such as to permit the standby generator to carry its full rated load as quickly as is safe and practicable, subject to a maximum period of 45 s.
3.4.2.6 For the safety of power supply to essential services, suitable load shedding devices are to be provided to automatically cut off the non-essential loads:
(1) when the total load exceeds the rated output power of generator caused by automatic switch-on of additional loads;
(2) when the total load exceeds the sum of rated powers of other generating sets which are still in service in case of the failure of one of generators as more than one generating sets are operating in parallel.

Section 5 AUXILIARY MACHINERY

3.5.1 General requirements

3.5.1.1 The auxiliary machinery referred to in this Section means the prime mover of electric generators, all kinds of pumps and air compressors serving the main propulsion machinery, etc.

3.5.1.2 During the unattended period of machinery spaces, all the auxiliary machinery are to be capable of being normally operated automatically.

3.5.2 Auxiliary diesel engines

3.5.2.1 The items to be automatically controlled and monitored for the auxiliary diesel engines are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

3.5.3 Pumps

3.5.3.1 The motor-driven pumps serving the main propulsion machinery are to be capable of being automatically started in sequence upon restoration of power after interruption. For the requirements for automatic changeover of standby pumps, see items marked with "c" in column 4 of Table 3.10.1.1 of this Chapter.

3.5.4 Air compressors

3.5.4.1 The items to be automatically controlled and monitored for air compressors are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

Section 6 OTHER EQUIPMENT

3.6.1 Bearings of tail pipes

3.6.1.1 The items to be automatically controlled and monitored for bearings of tail pipes are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

3.6.2 Valves

3.6.2.1 The valves covered by this Section mean the valves used in bilge and sea water systems (including ballast water system).

3.6.2.2 Failure of actuator power is not to put the valve and the whole ship to an unsafe condition.

3.6.2.3 Positive indication is to be provided at the station for valve control to show the actual valve position or alternatively, whether the valve is fully open or closed.

3.6.2.4 Operating equipment located in places which may be flooded is to be capable of normal operation when submerged.

3.6.2.5 In the event of a failure of the remote or automatic control the valves are to be capable of being operated manually.

3.6.3 Oil purifiers, etc.

3.6.3.1 The items to be automatically controlled and monitored for oil purifiers, oil return tanks of main and auxiliary engines and incinerators are to be in compliance with Table 3.10.1.1 of this Chapter as appropriate.

3.6.4 Oil tanks

3.6.4.1 The capacities of fuel oil daily service and settling tanks are to be appropriate to the consumption necessary for the unattended period (such as 8 h, 16 h, 24 h) plus 10% at least. A low level alarm is to be provided for the daily service fuel oil tanks (see Table 3.10.1.1 of this Chapter) and high and low level alarms are to be provided for the settling tanks.

3.6.4.2 Where the daily service fuel oil tanks are replenished automatically or remotely, means are to be provided to eliminate the possibility of overflow, and high and low level alarms are to be provided and extended to the BCS. In this case, the tanks may be exempted from the requirements for capacity as specified in 3.6.4.1 above.

Section 7 ADDITIONAL REQUIREMENTS FOR CONTROL STATIONS (ROOMS)

3.7.1 Provision of control stations (rooms)

3.7.1.1 Bridge control station (BCS), engine room centralized control station (ISC) and local control stations (LCS) are in general to be provided on ships with machinery spaces periodically unattended.

3.7.2 Functions of bridge control stations (BCS)

3.7.2.1 Under all sailing conditions including maneuvering, the speed and direction of thrust of main propulsion machinery as well as other associated installations (if fitted) are to be effectively controlled from the BCS. When necessary, the control is to be capable of being changed over to other control stations at any time and the changeover is to comply with the relevant requirements of 2.5.2 of this PART. The design and arrangement of bridge control station are to comply with the requirements in Section 8, Chapter 2 of this PART.

3.7.2.2 Alarms at the BCS

(1) For the items to be alarmed at the BCS and the mode of alarms, see column 5 of Table 3.10.1.1 of this Chapter. Alarms indicating the faults in the machinery and electrical equipment as well as the automated control and monitoring systems are, in general, to be relayed to the BCS in the following modes: group alarms for the protective actions of safety systems; separate alarms; group alarms for serious faults and group alarms for general faults.

(2) The audible alarms at the BCS are permitted to be silenced after acknowledgment, but the visual alarms are to be extinguished only after the rectification of faults, and furthermore, the visual signals are to be capable of being clearly distinguishable before and after acknowledgment.

3.7.2.3 If the main engine is remotely started from the bridge control station, the indicator is to be fitted on the bridge control station for the starting air pressure or voltage of starting storage batteries of main engines.

3.7.3 Functions of centralized control stations (rooms) of engine room (ISC)

3.7.3.1 The ISC is to be capable of performing functions of control and changeover of the main propulsion machinery as specified in 3.7.2.1 of this Section, and besides, it is also to be capable of controlling and monitoring the other equipment as specified in 3.1.1.4 of this Chapter.

3.7.3.2 Instruments or display units are to be provided at the ISC to indicate the essential parameters for ensuring the safe and reliable operation of the machinery and electrical equipment. The items to be displayed are given in column 2 of Table 3.10.1.1of this Chapter.

3.7.3.3 All faults including several faults occurred at the same time in the machinery and electrical equipment and in the control and monitoring systems are to be capable of being alarmed at the ISC. The items to be alarmed are given in column 3 of Table 3.10.1.1of this Chapter.

3.7.3.4 Audible alarms at the ISC are to be capable of being silenced only after being acknowledged at the station.

3.7.3.5 The emergency button for stopping main propulsion machinery and the emergency buttons for cutting off oil supply to boilers and incinerators provided at the ISC are to be independent of the automated systems of the station, but their actuating units may not be required to be independent and are to be arranged so as to preclude inadvertent operation.

3.7.3.6 Where overriding function as prescribed in 1.1.2.1(9) of this PART is provided for main engines, the overriding function is also to be provided at the ISC, and is to be so arranged as to preclude inadvertent operation.

3.7.4 Functions of local control stations (LCS)

3.7.4.1 The LCS is to comply with the requirements of 2.5.1.5 of this PART.

3.7.5 Communication

3.7.5.1 In addition to complying with the relevant requirements of PARTs THREE and FOUR of the Rules, reliable means of vocal communication are to be provided between the ISC or the LCS (if applicable), the BCS and the engineers' accommodation.

Section 8 ADDITIONAL REQUIREMENTS FOR CONTROL AND MONITORING SYSTEMS

3.8.1 Safety systems

3.8.1.1 The safety systems in all controlled and monitored machinery and electrical equipment are to be in compliance with the requirements of Section 3, Chapter 2 of this PART.

3.8.2 Alarm systems

3.8.2.1 The arrangement of the alarm display is to assist in identifying the particular fault condition and its location within the machinery space.

3.8.2.2 If the bridge navigating officer of the watch is the sole watch-keeper then, in the event of a machinery fault being monitored at the control location for machinery, the alarm system is to be such that this watch-keeper is made aware when:

(1) a machinery fault has occurred;

(2) the machinery fault is being attended to (e.g. acknowledging, silencing);

(3) the machinery fault has been rectified. Alternative means of communication between the bridge area, the accommodation for engineering personnel and the machinery spaces (ISC or local control stations) may be used for this function.

3.8.2.3 Group alarms may be arranged on the bridge to indicate machinery faults. Alarms associated with faults requiring speed reduction or automatic shutdown of propulsion machinery are to be separately identified (see column 5 in Table 3.10.1.1 of this Chapter).

3.8.2.4 The alarm system is to be capable of being tested during normal machinery operation. Where practicable, means are to be provided at convenient and accessible positions to permit the sensors to be tested without affecting the operation of the machinery.

3.8.2.5 If an alarm has been acknowledged and a second fault occurs before the first is rectified, then audible and visual alarms are to operate again. Alarms due to temporary failures are to remain activated until acknowledged.

3.8.2.6 Automatic recording devices are to be provided at the ISC for recording the important parameters and faults. Where a computer system is used, its recording device may be adopted instead.

3.8.2.7 A changeover switch is to be provided to relay all the fault alarms to the engineers' accommodation and each engineer's cabin by group alarms so as to ensure that the alarm signal is relayed at least to one cabin of the engineer on watch.

Acknowledgment of alarms at positions outside a machinery space (including the ISC) is not to silence the audible alarm or extinguish the visual alarm in that machinery space (including the ISC).

Where an alarm has not been acknowledged in a certain time (not more than 5 min) in the machinery space (including the ISC), the alarm system referred to in 2.8.4 of Chapter 2, PART FOUR of the Rules is to be activated automatically, and the alarm is to be clearly audible within the engineers' accommodation and related public spaces.

Section 9 FIRE PRECAUTIONS AND PROTECTION AGAINST FLOODING

3.9.1 Fire precautions

3.9.1.1 The fire precautions for periodically unattended machinery spaces (including the ISC) are to comply with the relevant requirements of PART SIX of the Rules, inter alia, the requirements for the special arrangements in machinery spaces, fire detection and alarm systems, and water fire-extinguishing systems. There is to be immediate water delivery from the fire main system at a suitable pressure, either by remote starting of one of the main fire pumps with remote starting from the navigating bridge or fire control station, if any, or permanent pressurization of the fire main system by one of the main fire pumps, except that this requirement need not be complied with for cargo ships of less than 1,600 gross tonnage if the fire pump starting arrangement in the machinery space is in an easily accessible position.

3.9.1.2 In addition to complying with the requirements for engine rooms given in PART THREE of the Rules, the fire precautions for periodically unattended machinery spaces are to comply with the following.

(1) Fuel oil, lubricating oil and hydraulic oil pipelines are to be so constructed and arranged as to avoid excessive stresses due to vibration and expansion. Flange joints are to be minimized as far as practicable in the above pipelines.

(2) Equipment for the automatic treatment of flammable oils, such as oil purifiers, oil heaters, oil filters, oil pumps, etc., are to be provided with means to prevent oil spillage, for instance, drip trays fitted below the equipment for collecting oil leakage and draining it to a sludge tank. The above-mentioned equipment is to be centralized as far as practicable in a special space.
(3) The high pressure fuel oil pipelines are to be screened or otherwise suitably protected to prevent leaks from dripping or spraying onto hot surfaces or into machinery air intakes, for instance, the fitting of metal sheathing to the high pressure fuel injection pipes of diesel engines.
(4) Leakage from high pressure fuel pipes are to be, as far as practicable, collected and led to a collector tank(s) fitted in a safe position and arrangements are to be provided for an alarm to be given in the event of leakage, see Table 3.10.1.1 of this Chapter.
(5) Fuel oil or lubricating oil heaters are to comply with the following:

① high temperature alarm or low flow alarm is to be provided unless it is impossible to reach the ignition temperature of medium;

② in addition to the temperature control, an independent safeguard is to be fitted which will automatically cut off the heating supply in the event of excessively high temperatures or loss of flow, except where the maximum temperature of the heating media remains limited to a value below 220℃;

③ where electric heaters are adopted, an independent safeguard is to be fitted which will automatically cut off the heating supply in the event of excessively high temperatures, except that all live heating components are soaked in oil and the surface temperature of the heating components remains below 220℃.

3.9.1.3 Special requirements for fire detection systems
(1) An automatic fire detection system is to be fitted in the machinery spaces.
(2) The system is to be designed with self-monitoring properties. Power or system failures are to initiate an audible alarm distinguishable from the fire alarm.
(3) The fire detection indicating panel is to be located on the navigation bridge, fire control station, or other accessible place where a fire in the machinery space will not render it inoperative.
(4) The fire detection indicating panel is to indicate the place of the detected fire in accordance with the arranged fire zones by means of a visual signal. Audible signals clearly distinguishable in character from any other audible signals are to be audible throughout the navigation bridge and the accommodation area of the personnel responsible for the operation of the machinery space.
(5) Fire detectors are to be of such types, and so located, that they will rapidly detect the onset of fire in conditions normally present in the machinery space. Consideration is to be given to avoiding false alarms. The type and location of detectors are to comply with the relevant requirements of the International Convention for the Safety of Life at Sea, 1974 (hereinafter referred to as SOLAS Convention) and the International Code for Fire Safety Systems (hereinafter referred to as FSS Code) as well as ISC rules. A combination of detector types is recommended in order to enable the system to react to more than one type of fire symptom.
(6) Fire detector zones are to be arranged in a manner that will enable the operating staff to locate the seat of the fire. The arrangement of the fire detection system, the number of loops and the location of detector heads are to be approved in each case and comply with the relevant requirements of SOLAS Convention and FSS Code. Air currents created by the machinery are not to render the detection system ineffective.
(7) When fire detectors are provided with the means to adjust their sensitivity, necessary arrangements are to be ensured to fix and identify the set point.
(8) When it is intended that a particular loop or detector is to be temporarily switched off, this state is to be clearly indicated. Reactivation of the loop or detector is to be performed automatically after a preset time.
(9) The fire detection indicating panel is to be provided with facilities for functional testing.
(10) The fire detection system is to be fed automatically from the emergency source of power by separate feeder if the main source of power fails, and to comply with the requirements of 2.9.6, PART FOUR of the Rules.
(11) Facilities are to be provided in the fire detection system to release manually the fire alarm from the passageways having entrances to engine and boiler rooms, navigation bridge and control station in engine room.
(12) The fire detection system is to be tested upon installation on board to confirm compliance with the rule requirements for function.

3.9.2 Protection against flooding

3.9.2.1 An alarm system is to be provided to warn high bilge water level in machinery spaces. The alarm level is to be sufficiently low to prevent liquid overflowing from the bilge onto the tank top of double bottom tanks.
3.9.2.2 The number and location of bilge water level detectors are to be such as to prevent false alarms at normal angles of trim and heel.
3.9.2.3 The location of the controls of any valve serving a sea inlet, a discharge below the waterline or a bilge injection system, for controlling flooding upon damage, is to be such as to allow adequate time for operation in case of influx of water to the space, having regard to at least 10 min which could be required to reach and close the valve. Arrangements are to be made to operate the controls from a position above the level to which the space could become flooded due to any broken pipe with the ship being in the fully loaded condition.
3.9.2.4 Bilge wells are to be large enough to accommodate normal drainage during the unattended period. Where the bilge pumps are arranged to start automatically, smaller bilge wells may be permitted to accommodate the normal drainage for a suitable time, provided that an alarm is provided to indicate if the influx of liquid is greater than the pump capacity or if the pump is operating more frequently than would normally be expected and that the discharge complies with the relevant requirements for pollution prevention. The items to be controlled and monitored are indicated in Table 3.10.1.1 of this Chapter as appropriate.
3.9.2.5 Alarms required by 3.9.2.1 and 3.9.2.4 above are to be given at the ISC, BCS and engineers' accommodation area.

Section 10 AUTOMATIC CONTROL AND MONITORING ITEMS

3.10.1 Table of automatic control and monitoring items

3.10.1.1 The automatic control and monitoring items (if fitted) for all ships with the class notation AUT-0 are to comply with Table 3.10.1.1.
3.10.1.2 The designations used in Table 3.10.1.1 of this Section are defined as follows:

–: not required;
*: only required for trunk piston diesel engines;
a: Mode a protective action, such as emergency shutdown of the engine, fuel oil cutoff of boiler and cutoff of electric power supply, etc.;
b: Mode b protective action, such as reducing the speed of rotation or the output of machinery;
c: Mode c protective action, such as starting and putting into operation of standby pump or standby unit;
S: single alarm;
G_a: group alarm activated by Mode a protective action;
G_b: group alarm activated by Mode b protective action;
R: group alarm for serious faults;
Y: group alarm for general faults.

3.10.1.3 Where "per cylinder" appears in the column "Remark" of Table 3.10.1.1 of this Section, it applies only to crosshead diesel engines, and for trunk piston diesel engines, "fitted on manifold outlet" may be used to replace the "per cylinder".
3.10.1.4 For the equipment marked with "▲" in Table 3.10.1.1 of this Section, if all of the single alarms and display items provided locally or in the vicinity of the engine are confirmed by ISC, the engine room central control station and the BCS may be exempted from the single alarms and display items as required in Table 3.10.1.1. Only one group alarm for general faults and one fault display are to be provided in this case.

Automatic Control and Monitoring Items for Ships with Class Notation AUT-0

Table 3.10.1.1

Item	ISC		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
1. Main diesel engine 1.1 Fuel oil system					
Fuel oil inlet pressure	Pressure	Low	c	*R*	Fitted after filter
Fuel oil temperature or viscosity	Temp. or	Low and	–	*Y*	Only for heavy oil

Item	ISC		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
(before injection pumps)	viscosity	high			
Leakage from high pressure fuel pipes	–	Leakage	–	*Y*	
Level of fuel oil in daily service tanks	–	Low	–	*Y*	High-level alarm also required, if no suitable overflow arrangement provided
Common rail fuel oil pressure	–	Low	–	*Y*	
1.2 Lubricating oil system					
Lub-oil inlet pressure to main bearing & thrust bearing	Pressure	Low	c	*R*	
			b	G_b	Necessary for crosshead diesel engines
		Excessively low	a	G_a	
Lub-oil inlet pressure to crosshead bearing	Pressure	Low	c	*R*	Required if separate lub-oil system installed for crosshead diesel engines
			b	G_b	
		Excessively low	a	G_a	
Lub-oil inlet pressure to camshaft	Pressure	Low	c	*R*	
		Excessively low	a	G_a	
Lub-oil inlet temperature to camshaft	Temp.	High	–	*Y*	
*Lub-oil filter differential pressure	Pressure	Great	–	*Y*	
Lub-oil inlet temperature	Temp.	High	–	*Y*	
Thrust bearing pad temperature or bearing temperature	Temp.	High	b	G_b	Necessary for crosshead diesel engines
		Excessively high	a	G_a	
Oil mist concentration in crankcase (or main, crank, crosshead bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	b	G_b	Applicable to low speed crosshead diesel engines specified in 9.7.6, Ch.9, Pt.3
*Oil mist concentration in crankcase (or main, crank bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	a	G_a	Applicable to diesel engines specified in 9.7.6, Ch.9, Pt.3; one oil mist detector for each engine having two independent outputs for initiating the alarm and shutdown would satisfy the requirement for independence between alarm and shutdown systems
Flow rate of cylinder lubricator (each apparatus)	–	Small	b	G_b	Required for trunk piston diesel engines if necessary for safe operation of the engines
Oil level in lub-oil circulating tank	–	Low	–	*Y*	Necessary for crosshead diesel engines; individual level alarms required for the tanks if separate lub-oil systems installed (e.g. camshaft, rocker arms, etc.) for crosshead diesel engines
Common rail servo oil pressure	–	Low	–	*Y*	
1.3 Turbocharger system					
Turbocharger lub-oil inlet pressure	Pressure	Low	–	*Y*	Unless provided with a self-contained lubricating oil system integrated with the turbocharger
Turbocharger lub-oil outlet temp each bearing	Temp	High	–	*Y*	Where outlet temperature from each bearing cannot be monitored due to the

Item	ISC		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
					engine/turbocharger design, alternative arrangements may be accepted. Continuous monitoring of inlet pressure and inlet temperature in combination with specific intervals for bearing inspection in accordance with the turbocharger manufacturer's instructions may be accepted as an alternative.
Speed of turbocharger	Speed	High	–	–	Applicable to Class B and C turbochargers (refer to 9.6.2, Ch.9, Pt.3)
1.4 Piston cooling system (Necessary for crosshead diesel engines)					
Piston coolant inlet pressure	Pressure	Low	c	*Y*	The slowdown is not required if the coolant oil taken from the main cooling system of the engine
		Excessively low	b	G_b	
Piston coolant outlet flow	–	Low	b	G_b	Per cylinder; where outlet flow cannot be monitored due to engine design, alternative arrangement may be accepted
Piston coolant outlet temperature	Temp.	High	b	G_b	Per cylinder
Level of piston coolant in expansion tank	–	Low	–	*Y*	
1.5 Seawater cooling system					
Pressure of cooling seawater	Pressure	Low	c	*Y*	
1.6 Cylinder fresh cooling water system					
Cylinder water inlet pressure or flow	Pressure or flow	Low	c	*Y*	Only cylinder coolant inlet pressure required for crosshead diesel engines
		Excessively low	b	G_b	
Cylinder water outlet temperature (from each cylinder) Cylinder water outlet temperature (general)	Temp.	High	b	G_b	Required for crosshead diesel engines where one common cooling space without individual stop valves is employed for all cylinder jackets. For trunk piston diesel engines, alarm and slowdown only for cylinder water outlet temperature (general) and two separate sensors required
Oily contamination of main engine cooling water system	–	Contaminated	–	–	Necessary for crosshead diesel engines; required where main engine cooling water is used in fuel and lubricating oil heat exchangers
Level of cylinder cooling water in expansion tank	–	Low	–	*Y*	
1.7 Starting and control air systems					
Starting air pressure before main shut-off valve	Pressure	Low	–	*S*	
Control air pressure	Pressure	Low	–	*S*	
Safety air pressure	Pressure	Low	–	*S*	Necessary for crosshead diesel engines
1.8 Scavenge air system					
Scavenge air receiver pressure	Pressure	–	–	–	Necessary for crosshead diesel engines
Scavenge air box temperature (fire)	Temp.	High	b	G_b	
Scavenge air receiver water level	–	High	–	*Y*	

Item	ISC		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
*Scavenge air receiver temperature	Temp.	High	–	*Y*	
1.9 Exhaust gas system					
Exhaust gas temp. after each cylinder	Temp.	High	b	G_b	For trunk piston diesel engines having a power of more than 500 kW per cylinder only
Exhaust gas temperature after each cylinder. Deviation from average	–	Great	–	*R*	
Exhaust gas temperature before each turbocharger	Temp.	High	–	*R*	Necessary for crosshead diesel engines
Exhaust gas temperature after each turbocharger	Temp.	High	–	*R*	
1.10 Fuel valve coolant					
Pressure of fuel valve coolant	Pressure	Low	c	*R*	The requirement is to be complied with if the crosshead diesel engine is fitted with a separate fuel valve cooling system
Temperature of fuel valve coolant	Temp.	High	–	*Y*	
Level of fuel valve coolant in expansion tank	–	Low	–	*Y*	
1.11 Engine speed/direction of rotation					
Speed	Speed	Overspeed	a	G_a	See 9.7.9.1 of Pt.3
Direction of rotation	Direction of rotation	Wrong way	–	*S*	Necessary for crosshead diesel engines
1.12 Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	*Y*	Indication of voltage may be replaced by indicating lamp
2 Auxiliary diesel engines▲					
Lub-oil inlet pressure	Pressure	Low	–	*Y*	
		Excessively low	a		
Fuel oil temperature or viscosity (before injection pumps)	Temp. or viscosity	Low or high	–	*Y*	Only for heavy oil
Exhaust gas temp. after each cylinder	Temp.	High	–	*Y*	For engine power > 500 kW per cylinder only
Lub-oil inlet temperature	–	High	–	*Y*	
Temperature of cooling water or cooling air outlet	Temp.	High	–	*Y*	
Pressure or flow of cooling water	–	Low	–	*Y*	
Speed	–	Overspeed	a	*Y*	See 9.7.10.3 of Pt.3
Starting air pressure	Pressure	Low	–	*Y*	
Fuel oil leakage from pressure pipes	–	Leakage	–	*Y*	
Oil mist concentration in crankcase (or main, crank bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	a	*Y*	Applicable to diesel engines specified in 9.7.6, Ch.9, Pt.3; one oil mist detector for each engine having two independent outputs for initiating the alarm and shutdown would satisfy the requirement for independence between alarm and shutdown systems
Level in fuel oil daily service tank	–	Low	–	*Y*	
Level in cooling water expansion tank	–	Low	–	*Y*	If not connected to main system
Common rail fuel oil pressure	–	Low	–	*Y*	
Common rail servo oil pressure	–	Low	–	*Y*	
Speed of turbocharger	Speed	High	–	–	Applicable to Class B and C turbochargers (refer to 9.6.2, Ch.9, Pt.3)
Power supply for control-safety-alarm systems	Electrical, pneumatic	Loss	–	*Y*	Indication of voltage may be replaced by indicating lamp

CHAPTER 4 REQUIREMENTS FOR MACHINERY NOTATIONS OF CONSTANTLY ATTENDED MACHINERY SPACES

Section 1 GENERAL PROVISIONS

4.1.1 Application

4.1.1.1 This Chapter applies to ships with machinery spaces (including the ISC) constantly attended by watch-keepers, and intended to be assigned machinery notations MCC and/or BRC.

4.1.1.2 In addition to this Chapter, ships intended to be assigned the above-mentioned machinery notations are to comply with the applicable requirements of Chapters 1 and 2 of this PART.

Section 2 REQUIREMENTS FOR AUTOMATION OF SHIPS WITH CLASS NOTATION MCC

4.2.1 Provision of control stations (rooms)

4.2.1.1 Ships with the class notation MCC are to be provided with the ISC and the LCS. When the machinery and electrical equipment are in normal operation, the ISC is to be constantly attended by watch-keepers.

4.2.2 Functions of the ISC

4.2.2.1 The control and monitoring functions of the ISC is to be in compliance with the following requirements:

(1) The starting, speed regulating, reversing (including shaft reversing) and stopping as well as blade angle (or pitches) of the main propulsion machinery are to be capable of being remotely controlled or automatically, sequentially controlled from the ISC. When necessary, the control is to be capable of being changed over to other control stations (rooms) at any time and the changeover is to comply with the relevant requirements of 2.5.2 in this PART. In addition, the other machinery and electrical equipment mentioned in 3.1.1.4 of this PART are to be controlled and monitored automatically.

(2) The design and arrangement of centralized control station of engine room are to comply with the following requirements:

① in principle, the remote control from the ISC to main propulsion machinery is to be performed by a single control device for each independent propeller, with automatic performance of all associated services including, where necessary, means of preventing overload and prolonged running in critical speed ranges of the propelling machinery;

② the control system of the ISC is to be independent from the other communication system, however, one control lever for both systems may be accepted;

③ operations following any setting of the ISC including reversing from the maximum ahead service speed in case of emergency are to take place in an automatic sequence and within time intervals acceptable to the machinery;

④ remote starting of the propulsion machinery in the ISC is to be automatically inhibited if conditions exist which may hazard the machinery, e.g., shaft turning gear engaged, drop of lubricating oil pressure;

⑤ the design of the control system in the ISC is to be such that in case of its failure an alarm is given. In this case, the speed and direction of the propeller are to be maintained until local control is in operation, unless this is considered impracticable. In particular, lack of power (electric, pneumatic, hydraulic) or changeover of control is not to lead to major and sudden change in propulsion power or propulsion direction.

(3) Instruments and display units are to be provided at the ISC to indicate the essential parameters for ensuring the safe and reliable operation of the machinery and electrical equipment. The items to be displayed are given in column 2 of Table 4.2.6.1 of this Chapter.

(4) All faults, including several faults occurred at the same time in the machinery and electrical equipment and in the control and monitoring systems are to be capable of being alarmed at the ISC. The items to be alarmed are given in column 3 of Table 4.2.6.1 of this Chapter.

(5) Audible alarms at the ISC are to be capable of being silenced only after being acknowledged at the station.
(6) The emergency button for stopping the main propulsion machinery and the emergency button for cutting off oil supply to boilers are to be provided at the ISC and independent of the control system, but their actuating units may not be independent, and are to be so arranged as to preclude inadvertent touching.
(7) Where overriding function is provided for the main engine, such function is also to be provided at the ISC, and is to be so arranged as to preclude inadvertent touching.

4.2.2.2 The functions of automatic and remote control of all the machinery and electrical equipment specified in 3.1.1.4 of this PART are to be, in general, in compliance with the requirements of Sections 2, 3, 5 and 6 of Chapter 3 of this PART. However, the intervention of some control processes by the attendant in the ISC is permitted, provided that the attendant is competent to perform such control, such as the employment of remote control to substitute some items in the automatic control.

4.2.2.3 For the safety system, Mode a protective action is to be carried out automatically, Modes b and c protective actions may be carried out automatically or by manual operation in the ISC.

4.2.3 Functions of the local control station (LCS)

4.2.3.1 The LCS is to comply with the requirements of 2.5.1.5 of this PART.

4.2.4 Fire precautions

4.2.4.1 The fire precautions are in general to comply with the requirements for fire detection and fire alarm systems in 3.9.1.3 of this PART (the areas of an engine room which can be seen from the ISC may be exempted from the required sensors) and the requirements in 3.9.1.2 (except (4)) of this PART.

4.2.5 Protection against flooding

4.2.5.1 A bilge high level alarm system is to be provided.

4.2.5.2 The overboard discharge of bilge is to comply with the relevant requirements for pollution prevention.

4.2.6 Table of automatic control and monitoring items

4.2.6.1 The automatic control and monitoring items (if fitted) for all ships with the class notation MCC are to comply with Table 4.2.6.1.

4.2.6.2 The designations used in Table 4.2.6.1 of this Section are defined as follows:

−: not required;
*: only required for trunk piston diesel engines;
a: Mode a protective action, such as emergency shutdown of the engine, fuel oil cutoff of boiler and cutoff of electric power supply, etc.;
b: Mode b protective action, such as reducing the speed of rotation or the output of machinery;
c: Mode c protective action, such as starting and putting into operation of standby pump or standby unit.

4.2.6.3 Where "per cylinder" appears in the column "Remark" of Table 4.2.6.1 of this Section, it applies only to crosshead diesel engines, and for trunk piston diesel engines, "fitted on manifold outlet" may be used to replace "per cylinder".

4.2.6.4 For the equipment marked with "▲" in Table 4.2.6.1 of this Section, if all of the single alarms and display items provided locally or in the vicinity of the engine are confirmed by ISC, the engine room central control station may be exempted from the single alarms and display items as required in Table 4.2.6.1. Only one group alarm for general faults and one fault display are to be provided in this case.

Automatic Control and Monitoring Items for Ships with Class Notation MCC

Table 4.2.6.1

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
1 Main diesel engine 1.1 Fuel oil system				
Fuel oil inlet pressure	Pressure	Low	c	Fitted after filter
Fuel oil temperature or viscosity (before injection pumps)	Temp. or viscosity	Low or high	–	Only for heavy oil
Leakage from high pressure fuel pipes	–	Leakage	–	

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
Level of fuel oil in daily service tanks	–	Low	–	High-level alarm also required, if no suitable overflow arrangement provided
Common rail fuel oil pressure	–	Low	–	
1.2 Lubricating oil system				
Lub-oil inlet pressure to main bearing & thrust bearing	Pressure	Low	c	
			b	Necessary for crosshead diesel engines
		Excessively low	a	
Lub-oil inlet pressure to crosshead bearing	Pressure	Low	c	Required if separate lub-oil system installed for crosshead diesel engines
			b	
		Excessively low	a	
Lub-oil inlet pressure to camshaft	Pressure	Low	c	
		Excessively low	a	
Lub-oil inlet temperature to camshaft	Temperature	High	–	
*Lub-oil filter differential pressure	Pressure	Great	–	
Lub-oil inlet temperature	Temperature	High	–	
Thrust bearing pad temperature or bearing temperature	Temperature	High	b	Necessary for crosshead diesel engines
		Excessively high	a	
Oil mist concentration in crankcase (or main, crank, crosshead bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	b	Applicable to low speed crosshead diesel engines specified in 9.7.6, Ch.9, Pt.3
*Oil mist concentration in crankcase (or main, crank bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	a	Applicable to diesel engines specified in 9.7.6, Ch.9, Pt.3; one oil mist detector for each engine having two independent outputs for initiating the alarm and shutdown would satisfy the requirement for independence between alarm and shutdown systems
Flow rate of cylinder lubricator. Each apparatus	–	Small	b	Required for trunk piston diesel engines if necessary for safe operation of the engines
Oil level in lub-oil circulating tank	–	Low	–	Necessary for crosshead diesel engines; individual level alarms required for the tanks if separate lub-oil systems installed (e.g. camshaft, rocker arms, etc.) for crosshead diesel engines
Common rail servo oil pressure	–	Low	–	
1.3 Turbocharger system				
Turbocharger lub-oil inlet pressure	Pressure	Low	–	Unless provided with a self-contained lubricating oil system integrated with the turbocharger
Turbocharger lub-oil outlet temp each bearing	Temp	High	–	Where outlet temperature from each bearing cannot be monitored due to the engine/turbocharger design, alternative arrangements may be accepted. Continuous monitoring of inlet pressure and inlet temperature in combination

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
				with specific intervals for bearing inspection in accordance with the turbocharger manufacturer's instructions may be accepted as an alternative
Speed of turbocharger	Speed	High	–	Applicable to Class B and C turbochargers (refer to 9.6.2, Ch.9, Pt.3)
1.4 Piston cooling system (Necessary for crosshead diesel engines)				
Piston coolant inlet pressure	Pressure	Low	c	The slowdown is not required if the coolant oil taken from the main cooling system of the engine
		Excessively low	b	
Piston coolant outlet flow	–	Low	b	Per cylinder; where outlet flow cannot be monitored due to engine design, alternative arrangement may be accepted
Piston coolant outlet temperature	Temp.	High	b	Per cylinder
Level of piston coolant in expansion tank	–	Low	–	
1.5 Seawater cooling system				
Pressure of cooling seawater	Pressure	Low	c	
1.6 Cylinder fresh cooling water system				
Cylinder water inlet pressure or flow	Pressure or flow	Low	c	Only cylinder coolant inlet pressure required for crosshead diesel engines
		Excessively low	b	
Cylinder water outlet temperature (from each cylinder) Cylinder water outlet temperature (general)	Temperature	High	b	Required for crosshead diesel engines where one common cooling space without individual stop valves is employed for all cylinder jackets. For trunk piston diesel engines, alarm and slowdown only for cylinder water outlet temperature (general) and two separate sensors required
Oily contamination of main engine cooling water system	–	Contaminated	–	Necessary for crosshead diesel engines; required where main engine cooling water is used in fuel and lubricating oil heat exchangers
Level of cylinder cooling water in expansion tank	–	Low	–	
1.7 Starting and control air systems				
Starting air pressure before main shut-off valve	Pressure	Low	–	
Control air pressure	Pressure	Low	–	
Safety air pressure	Pressure	Low	–	Necessary for crosshead diesel engines
1.8 Scavenge air system				
Scavenge air receiver pressure	Pressure	–	–	Necessary for crosshead diesel engines
Scavenge air box temperature (fire)	Temperature	High	b	
Scavenge air receiver water level	–	High	–	
*Scavenge air receiver temperature	Temperature	High	–	
1.9 Exhaust gas system				
Exhaust gas temp. after each cylinder	Temperature	High	b	For trunk piston diesel engines having a power of more than 500 kW per cylinder only
Exhaust gas temperature after each cylinder. Deviation from average	–	Great	–	
Exhaust gas temperature before each turbocharger	Temperature	High	–	Necessary for crosshead diesel engines

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
Exhaust gas temperature after each turbocharger	Temperature	High	–	
1.10 Fuel valve coolant				
Pressure of fuel valve coolant	Pressure	Low	c	The requirement is to be complied with if the crosshead diesel engine is fitted with a separate fuel valve cooling system
Temperature of fuel valve coolant	Temperature	High	–	
Level of fuel valve coolant in expansion tank	–	Low	–	
1.11 Engine speed/direction of rotation				
Speed	Speed	Overspeed	a	See 9.7.9.1 of Pt.3
Direction of rotation	Direction of rotation	Wrong way	–	Necessary for crosshead diesel engines
1.12 Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
2 Auxiliary diesel engines▲				
Lub-oil inlet pressure	Pressure	Low	–	
		Excessively low	a	
Fuel oil temperature or viscosity (before injection pumps)	Temperature or viscosity	Low or high	–	Only for heavy oil
Exhaust gas temp. after each cylinder	Temperature	High	–	For engine power > 500 kW per cylinder only
Lub-oil inlet temperature	–	High	–	
Temperature of cooling water or cooling air outlet	Temperature	High	–	
Pressure or flow of cooling water	–	Low	–	
Speed	–	Overspeed	a	See 9.7.10.3 of Pt.3
Starting air pressure	Pressure	Low	–	
Fuel oil leakage from pressure pipes	–	Leakage	–	
Oil mist concentration in crankcase (or main, crank bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	a	Applicable to diesel engines specified in 9.7.6, Ch.9, Pt.3; one oil mist detector for each engine having two independent outputs for initiating the alarm and shutdown would satisfy the requirement for independence between alarm and shutdown systems
Level in fuel oil daily service tank	–	Low	–	
Level in cooling water expansion tank	–	Low	–	If not connected to main system
Common rail fuel oil pressure	–	Low	–	
Common rail servo oil pressure	–	Low	–	
Speed of turbocharger	Speed	High	–	Applicable to Class B and C turbochargers (refer to 9.6.2, Ch.9, Pt.3)
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
3 Main gas turbines				
Lub-oil inlet pressure to gas turbine and gearing	Pressure	Low	c	
		Excessively low	a	
Lub-oil inlet temperature to gas turbine and gearing	Temperature	High	–	

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
Lub-oil filter differential pressure	–	Great	c	
Oil level in lub-oil circulating tank	–	Low	–	For gravity and circulating oil tanks
Turbine main bearing temperature	Temperature	High	–	
Coolant pressure or flow	–	Low	–	
Coolant temperature	Temperature	High	–	
Fuel oil temperature or viscosity	Temperature or viscosity	Low or high	–	Only for heavy oil
Fuel oil pressure or flow	Pressure or flow	Low	c	
Level in fuel oil daily service tank	–	Low	–	When it is replenished automatically, high and low level alarms are to be fitted
Gas inlet or outlet temperature of turbine	Temperature	High	–	
		Excessively high	a	
Deviation of exhaust gas temperature from average	–	High	–	
Gas turbine combustion chamber flame and ignition	–	Failure	a	
Gas turbine vibration	–	High	–	
		Excessively high	a	
Axial displacement of turbine rotor	–	Great	–	
Turbine speed	–	Overspeed	a	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
4 Auxiliary steam turbines▲				
Lub-oil inlet pressure for turbine and gearing	Pressure	Low	–	
		Excessively low	a	
Exhaust gas temperature	Temperature	High	a	
Combustion chamber flame	–	Extinguished	a	
Gas turbine vibration	–	Excessive	a	
Gas turbine speed	–	Overspeed	a	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
5 Main steam turbines				
Lub-oil inlet pressure for turbine and gearing	Pressure	Low	c	
		Excessively low	a	
Lub-oil inlet temperature for turbine and gearing	Temperature	High	–	
Lub-oil filter differential pressure	–	Great	–	
Level of lub-oil tank	–	Low	–	For gravity and circulating oil tanks
Bearing temperature or bearing lub-oil outlet temperature of turbine and gearing	Temperature	High	–	
Thrust bearing temperature or lub-oil outlet temperature	–	High	–	
Astern turbine exhaust steam temperature	Temperature	High	–	

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
Gland steam pressure	Pressure	High and low	–	
Circulating seawater pressure or flow	Pressure or flow	Low	c	
Condenser vacuum	Vacuum	Low	b	
Condenser condensate level	–	High and low	b	
Condensate pump	–	Stop/failure	–	
Condensate salinity	–	High	–	
Steam turbine vibration	–	Excessive	b	
Axial displacement of turbine rotor	–	Excessive	a	
Turbine speed	–	Overspeed	a	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
6 Auxiliary steam turbines▲				
Lub-oil inlet temperature for turbine and gearing	–	High	–	
Lub-oil inlet pressure for turbine and gearing	Pressure	Low	–	
		Excessively low	a	
Condenser vacuum	–	Low	a	
Axial displacement of turbine rotor	–	Excessive	a	
Turbine speed	–	Overspeed	a	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
7 Main steam boilers				
Steam drum or superheater outlet pressure	Pressure	High and low	–	
Superheated steam outlet temperature	Temperature	High	–	
De-superheated steam outlet temperature	Temperature	High	–	
Boiler feed water level	Level	High	–	At least 3 sensors fitted. See 3.3.1.2(1)② and 3.3.1.3(1)② of this PART
		Low	c	
		Excessively low	a	
Temperature or viscosity of oil fuel to burners	Temperature or viscosity	Low and high	–	Only for heavy oil. Protective action with cutoff of boiler fuel oil supply in case of excessively high temperature or excessively low viscosity may be carried out by cutoff of fuel oil heating supply
		Excessively low and high	a	
Fuel oil pressure to burners	Pressure	Low	c	See 3.3.1.3(3) of this PART
Forced draft pressure	Pressure	Loss	a	2 sensors fitted
Burner flame and ignition	–	Extinguished/ ignition failure	a	Each burner is to be monitored
Fuel oil atomizing steam (air) pressure	Pressure	Low	–	
Feed pump discharge pressure or flow	Pressure or flow	Low	c	See 3.3.1.3(4) of this PART
Feed water forced circulation flow	Flow	Low	a	Required for forced circulating boilers only
Level of feed water tank	–	Low	–	Required for daily feed water tanks only

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
Feed water salinity	–	High	–	
Water level of deaerator	–	High and low	–	
Boiler air supply casing and exhaust pipe (smoke uptake)	–	Fire	–	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
8 Auxiliary steam boilers▲				
Steam drum or superheater outlet pressure	Pressure	Low	–	
Boiler feed water level	–	High	–	See 3.3.1.2(1)② and 3.3.1.3(1)② of this PART
		Low	c	
		Excessively low	a	
Temperature or viscosity of oil fuel to burners	–	Low and high	–	Only for heavy oil. Protective action with cutoff of boiler fuel oil supply in case of excessively high temperature or excessively low viscosity may be carried out by cutoff of fuel oil heating supply
		Excessively low and high	a	
Fuel oil pressure to burners	Pressure	Low	c	See 3.3.1.3(3) of this PART
Forced draft pressure	–	Loss	a	
Burner flame and ignition	–	Extinguished/ ignition failure	a	
Feed water salinity	–	High	–	Only applicable to auxiliary steam boiler for driving turbine-generator set
Boiler air supply casing and exhaust pipe (smoke uptake)	–	Fire	–	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	Indication of voltage may be replaced by indicating lamp
9 Controllable pitch propeller				
Pitch or blade angle of controllable pitch propeller	Pitch or blade angle	–	–	See 2.8.1.11 of this PART
Propeller shaft speed	Speed	–	–	See 2.8.1.11 of this PART
Hydraulic system pressure for controlling propeller pitch	Pressure	Low	c	
Hydraulic oil tank level	–	Low	–	
Hydraulic oil temp. (if oil cooler is fitted)	–	High	–	
Electric power supply for electrohydraulic control system	Voltage	Loss	–	
10 Vibration damper				
Oil inlet pressure or amplitude for vibration damper	Pressure or amplitude	Low or great	–	See 3.2.2.5 of this PART and 12.1.4.3 of Pt.3
11 Gearbox (for main propulsion machinery)				
Lub-oil inlet pressure of gearbox	Pressure	Low	c	
		Excessively low	a	
Lub-oil inlet temperature of gearbox	Temperature	High	–	

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm		
1	2	3	4	5
Gear oil pressure	Pressure	Low	–	
12 Clutches				
Clutch position	Position	–	–	
Power supply for control of clutches (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	See 2.8.1.11 of this PART
13 Stern tube bearing				
Oil lubricated stern tube bearing temp.	–	High	–	
Level of stern tube lubricating oil tank	–	Low	–	
14 Air compressors▲				
Air compressor lubricating oil pressure	–	Low	a	Except for splash lubrication
15 Thermal oil heaters▲				
(1) Oil-fired				
Thermal oil expansion tank level	–	Low	a	
Thermal oil flow or pressure	–	Low	a	
Thermal oil outlet temperature	–	High	a	
Combustion air pressure or forced ventilation	–	Low or shutoff	a	
Fuel oil pressure	–	Excessively low	c	
Fuel oil temperature or viscosity	–	Low or great	–	Only for heavy oil
Uptake temperature	–	High	a	
Burner flame and ignition	–	Extinguished/ ignition failure	a	Each burner is to be monitored
(2) Exhaust-fired				
Thermal oil expansion tank level	–	Low	a	
Thermal oil flow or pressure	–	Low	a	
Thermal oil outlet temperature	–	High	a	
Exhaust temperature	–	High	–	
16 Oil purifier▲				
Purifier oil outlet pressure	Pressure	Low	–	
Purifier oil inlet temperature	–	High	–	
17 Sludge tank				
Level of sludge tank	–	High	–	
18 Bilge				
Bilge level	–	High	–	See 3.9.2.1 of this PART
Bilge pumps	Indication for operation time	Too long or more frequently	–	For automatically controlled bilge pumps only, see 3.9.2.4 of this PART
19 Diesel engines driving propulsion generators				
Fuel oil inlet pressure	Pressure	Low	–	Fitted after filter
Fuel oil temperature or viscosity (before injection pumps)	Temp. or viscosity	Low or high	–	Only for heavy oil
High pressure fuel pipes	–	Leakage	–	
Level of fuel oil in daily service tank	–	Low	–	
Common rail fuel oil pressure	–	Low	–	
Common rail servo oil pressure	–	Low	–	
Lub-oil inlet pressure	Pressure	Low	–	
		Excessively low	a	
Lub-oil filter differential pressure	Pressure	Great	–	
Lub-oil inlet temperature	–	High	–	
Speed of turbocharger	Speed	High	–	Applicable to Class B and C

Item	ISC		Mode of protective control action	Remark
	Display	Limit alarm

Section 3 REQUIREMENTS FOR AUTOMATION OF SHIPS WITH CLASS NOTATION BRC

4.3.1 General requirements

4.3.1.1 Ships with the class notation BRC are to be provided with the remote control of the main propulsion machinery and other related installations from the BCS. The machinery spaces are to be constantly attended by watch-keepers to look after the machinery and electrical equipment as described in 3.1.1.4 of this PART.

4.3.2 Functions of the BCS

4.3.2.1 Under all sailing conditions including maneuvering, the speed and direction of thrust of main propulsion machinery as well as other installations (if fitted) are to be effectively controlled from the BCS. The design and arrangement of BCS are to comply with the requirements of Section 8, Chapter 2 of this PART.

4.3.2.2 Where necessary, the control of propulsion machinery from the BCS is to be capable of being changed over to the local control station at any time and the changeover of the control is to comply with the relevant requirements of 2.5.2 of this PART.

4.3.2.3 The automatic and remote control of main engines, clutches, controllable pitch propeller, etc. is to be, in general, in compliance with the relevant requirements of Section 2, Chapter 3 of this PART.

4.3.2.4 The Mode a protective action of main engines is to be capable of being carried out automatically, the other actions (Mode b and Mode c) may be carried out by manual operation.

4.3.2.5 The bridge control of main steam turbines is to comply with the requirements in 3.2.3.2 of this PART. If the slow-turning device is arranged to be operated manually, automatic operation will not be required.

4.3.2.6 Alarms at the BCS:

(1) For the items to be alarmed at the BCS and the mode of alarms, see column 5 of Table 4.3.4.1 of this Section. Alarms indicating the faults in the machinery and electrical equipment as well as the automated control and monitoring systems are, in general, to be relayed to the BCS in the following modes: group alarms for the protective actions of safety systems; separate alarms; group alarms for serious faults and group alarms for general faults.

(2) The audible alarms at the BCS are permitted to be silenced after acknowledgment, but the visual alarms are to be extinguished only after the rectification of faults, and furthermore, the visual signals are to be capable of being clearly distinguishable before and after acknowledgment.

4.3.2.7 If the main engine is remotely started from the bridge control station, the indicator is to be fitted on the bridge control station for the starting air pressure or voltage of starting storage batteries of main engines.

4.3.3 Functions of the LCS

4.3.3.1 The LCS is to comply with the requirements in 2.5.1.5 of this PART.

4.3.3.2 The items to be displayed and alarmed, as required in columns 2 and 3 of Table 4.3.4.1 of this Section for the propulsion machinery (such as main engines, clutches, controllable pitch propeller, etc.), are to be provided at the LCS.

4.3.4 Table of automatic control and monitoring items

4.3.4.1 The automatic control and monitoring items (if fitted) for all ships with the class notation BRC are to comply with Table 4.3.4.1.

4.3.4.2 The designations used in Table 4.3.4.1 of this Section are defined as follows:

−: not required;

*: only required for trunk piston diesel engines;

S: single alarm;

G_a: group alarm activated by Mode a protective action;

G_b: group alarm activated by Mode b protective action;

R: group alarm for serious faults;

Y: group alarm for general faults.

4.3.4.3 Where "per cylinder" appears in the column "Remark" of Table 4.3.4.1 of this Section, it applies only to crosshead diesel engines, and for trunk piston diesel engines, "fitted on manifold outlet" may be used to replace "per cylinder".

Automatic Control and Monitoring Items for Ships with Class Notation BRC

Table 4.3.4.1

Item	LCS		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
1 Main diesel engine					
1.1 Fuel oil system					
Fuel oil inlet pressure	Pressure	Low	c	*Y*	Fitted after filter
Fuel oil temperature or viscosity (before injection pumps)	Temp. or viscosity	Low or high	–	*Y*	Only for heavy oil
Leakage from high pressure fuel pipes	–	Leakage	–	*Y*	
Level of fuel oil in daily service tanks	–	Low	–	*Y*	High-level alarm also required, if no suitable overflow arrangement provided
Common rail fuel oil pressure	–	Low	–	*Y*	
1.2 Lubricating oil system					
Lub-oil inlet pressure to main bearing & thrust bearing	Pressure	Low	c	*Y*	
			b	G_b	Necessary for crosshead diesel engines
		Excessively low	a	G_a	
Lub-oil inlet pressure to crosshead bearing	Pressure	Low	c	*Y*	Required if separate lub-oil system installed for crosshead diesel engines
			b	G_b	
		Excessively low	a	G_a	
Lub-oil inlet pressure to camshaft	Pressure	Low	c	*Y*	
		Excessively low	a	G_a	
Lub-oil inlet temperature to camshaft	Temp.	High	–	*Y*	
*Lub-oil filter differential pressure	Pressure	Great	–	*Y*	
Lub-oil inlet temperature	Temp.	High	–	*Y*	
Thrust bearing pad temperature or bearing temperature	Temp.	High	b	G_b	Necessary for crosshead diesel engines
		Excessively high	a	G_a	

Item	LCS		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
Oil mist concentration in crankcase (or main, crank, crosshead bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	b	*Gb*	Applicable to low speed crosshead diesel engines specified in 9.7.6, Ch.9, Pt.3
*Oil mist concentration in crankcase (or main, crank bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	a	*Ga*	Applicable to diesel engines specified in 9.7.6, Ch.9, Pt.3; one oil mist detector for each engine having two independent outputs for initiating the alarm and shutdown would satisfy the requirement for independence between alarm and shutdown systems
Flow rate of cylinder lubricator. Each apparatus	–	Small	b	*Gb*	Required for trunk piston diesel engines if necessary for safe operation of the engines
Oil level in lub-oil circulating tank	–	Low	–	*Y*	Necessary for crosshead diesel engines; individual level alarms required for the tanks if separate lub-oil systems installed (e.g. camshaft, rocker arms, etc.) for crosshead diesel engines
Common rail servo oil pressure	–	Low	–	*Y*	
1.3 Turbocharger system					
Turbocharger lub-oil inlet pressure	Pressure	Low	–	*Y*	Unless provided with a self-contained lubricating oil system integrated with the turbocharger
Turbocharger lub-oil outlet temp each bearing	Temp.	High	–	*Y*	Where outlet temperature from each bearing cannot be monitored due to the engine/turbocharger design alternative arrangements may be accepted. Continuous monitoring of inlet pressure and inlet temperature in combination with specific intervals for bearing inspection in accordance with the turbocharger manufacturer's instructions may be accepted as an alternative
Speed of turbocharger	Speed	High	–	–	Applicable to Class B and C turbochargers (refer to 9.6.2, Ch.9, Pt.3)
1.4 Piston cooling system (Necessary for crosshead diesel engines)					
Piston coolant inlet pressure	Pressure	Low	c	*Y*	The slowdown is not required if the coolant oil taken from the main cooling system of the engine
		Excessively low	b	*Gb*	
Piston coolant outlet flow	–	Low	b	*Gb*	Per cylinder; where outlet flow cannot be monitored due to engine design, alternative arrangement may be accepted
Piston coolant outlet temperature	Temp.	High	b	*Gb*	Per cylinder
Level of piston coolant in expansion tank	–	Low	–	*Y*	
1.5 Seawater cooling system					
Pressure of cooling seawater	Pressure	Low	c	*Y*	
1.6 Cylinder fresh cooling water system					

Item	LCS		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
Cylinder water inlet pressure or flow	Pressure or flow	Low	c	*Y*	Only cylinder coolant inlet pressure required for crosshead diesel engines
		Excessively low	b	G_b	
Cylinder water outlet temperature (from each cylinder) Cylinder water outlet temperature (general)	Temp.	High	b	G_b	Required for crosshead diesel engines where one common cooling space without individual stop valves is employed for all cylinder jackets. For trunk piston diesel engines, alarm and slowdown only for cylinder water outlet temperature (general) and two separate sensors required
Oily contamination of main engine cooling water system	–	Contaminated	–	–	Necessary for crosshead diesel engines; required where main engine cooling water is used in fuel and lubricating oil heat exchangers
Level of cylinder cooling water in expansion tank	–	Low	–	*Y*	
1.7 Starting and control air systems					
Starting air pressure before main shut-off valve	Pressure	Low	–	*Y*	
Control air pressure	Pressure	Low	–	*Y*	
Safety air pressure	Pressure	Low	–	*Y*	Necessary for crosshead diesel engines
1.8 Scavenge air system					
Scavenge air receiver pressure	Pressure	–	–	–	Necessary for crosshead diesel engines
Scavenge air box temperature (fire)	Temp.	High	b	G_b	
Scavenge air receiver water level	–	High	–	*Y*	
*Scavenge air receiver temperature	Temp.	High	–	*Y*	
1.9 Exhaust gas system					
Exhaust gas temp. after each cylinder	Temp.	High	b	G_b	For trunk piston diesel engines having a power of more than 500 kW per cylinder only
Exhaust gas temperature after each cylinder. Deviation from average	–	Great	–	*Y*	
Exhaust gas temperature before each turbocharger	Temp.	High	–	*Y*	Necessary for crosshead diesel engines
Exhaust gas temperature after each turbocharger	Temp.	High	–	*Y*	
1.10 Fuel valve coolant					
Pressure of fuel valve coolant	Pressure	Low	c	*Y*	The requirement is to be complied with if the crosshead diesel engine is fitted with a separate fuel valve cooling system
Temperature of fuel valve coolant	Temp.	High	–	*Y*	
Level of fuel valve coolant in expansion tank	–	Low	–	*Y*	
1.11 Engine speed/direction of rotation					
Speed	Speed	Overspeed	a	G_a	See 9.7.9.1 of Pt.3
Direction of rotation	Direction of rotation	Wrong way	–	*Y*	Necessary for crosshead diesel engines
1.12 Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	*Y*	Indication of voltage may be replaced by indicating lamp
2 Main gas turbines					
Lub-oil inlet pressure to gas turbine and gearing	Pressure	Low	c	*R*	
		Excessively low	a	G_a	

Item	LCS		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
Lub-oil inlet temperature to gas turbine and gearing	Temp.	High	–	*Y*	
Lub-oil filter differential pressure	–	Great	c	*Y*	
Oil level in lub-oil circulating tank	–	Low	–	*Y*	For gravity and circulating oil tanks
Turbine main bearing temperature	Temp.	High	–	*Y*	
Coolant pressure or flow	–	Low	–	*Y*	
Coolant temperature	Temp.	High	–	*Y*	
Fuel oil temperature or viscosity	Temp. or viscosity	Low or high	–	*Y*	Only for heavy oil
Fuel oil pressure or flow	Pressure or flow	Low	c	*Y*	
Level in fuel oil daily service tank	–	Low	–	*Y*	When it is replenished automatically, high and low level alarms are to be fitted
Gas inlet or outlet temperature of turbine	Temp.	High	–	*Y*	
		Excessively high	a	G_a	
Deviation of exhaust gas temperature from average	–	High	–	*Y*	
Gas turbine combustion chamber flame and ignition	–	Failure	a	G_a	
Gas turbine vibration	–	High	–	*Y*	
		Excessively high	a	G_a	
Axial displacement of turbine rotor	–	Great	–	*R*	
Turbine speed	–	Overspeed	a	G_a	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	*Y*	Indication of voltage may be replaced by indicating lamp
3 Main steam turbines					
Lub-oil inlet pressure for turbine and gearing	Pressure	Low	c	*R*	
		Excessively low	a	G_a	
Lub-oil inlet temperature for turbine and gearing	Temp.	High	–	*Y*	
Lub-oil filter differential pressure	–	Great	–	*Y*	
Level of lub-oil tank	–	Low	–	*Y*	For gravity and circulating oil tanks
Bearing temperature or bearing lub-oil outlet temperature of turbine and gearing	Temp.	High	–	*Y*	
Thrust bearing temperature or lub-oil outlet temperature	–	High	–	*Y*	
Astern turbine exhaust steam temperature	Temp.	High	–	*Y*	
Gland steam pressure	Pressure	High and low	–	*Y*	
Circulating seawater pressure or flow	Pressure or flow	Low	c	*Y*	
Condenser vacuum	Vacuum	Low	b	G_b	
Condenser condensate level	–	High and low	b	G_b	
Condensate pump	–	Stop/ failure	–	*Y*	
Condensate salinity	–	High	–	*Y*	

Item	LCS		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
Steam turbine vibration	–	Excessive	b	G_b	
Axial displacement of turbine rotor	–	Excessive	a	G_a	
Turbine speed	–	Overspeed	a	G_a	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	*Y*	Indication of voltage may be replaced by indicating lamp
4 Controllable pitch propeller					
Blade angle (or pitch) of controllable pitch propeller	Blade angle or pitch	–	–	–	See 2.8.1.11 of this PART
Propeller shaft speed	Speed	–	–	–	See 2.8.1.11 of this PART
Hydraulic system pressure for controlling propeller pitch	Pressure	Low	c	*Y*	
Hydraulic oil tank level	–	Low	–	*Y*	
Hydraulic oil temp. (if oil cooler is fitted)	–	High	–	*Y*	
Electric power supply for electrohydraulic control system	Voltage	Loss	–	*Y*	
5 Vibration damper					
Oil inlet pressure or amplitude for vibration damper	Pressure or amplitude	Low or great	–	*Y*	See 3.2.2.5 of this PART and 12.1.4.3 of Pt.3
6 Gearbox (for main propulsion machinery)					
Lub-oil inlet pressure of gearbox	Pressure	Low	c	*Y*	
		Excessively low	a	G_a	
Lub-oil inlet temperature of gearbox	Temp.	High	–	*Y*	
Gear oil pressure	Pressure	Low	–	*Y*	
7 Clutches					
Clutch position	Position	–	–	–	
Power supply for control of clutches (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	*Y*	See 2.8.1.11 of this PART
8 Stern tube bearing					
Oil lubricated stern tube bearing temp.	–	High	–	*Y*	
Level of stern tube lubricating oil tank	–	Low	–	*Y*	
9 Diesel engines driving propulsion generators					
Fuel oil inlet pressure	Pressure	Low	–	*Y*	Fitted after filter
Fuel oil temperature or viscosity (before injection pumps)	Temp. or viscosity	Low or high	–	*Y*	Only for heavy oil
High pressure fuel pipes	–	Leakage	–	*Y*	
Level of fuel oil in daily service tank	–	Low	–	*Y*	
Common rail fuel oil pressure	–	Low	–		
Common rail servo oil pressure	–	Low	–		
Lub-oil inlet pressure	Pressure	Low	–	*Y*	
		Excessively low	a	G_a	
Lub-oil filter differential pressure	Pressure	Great	–	*Y*	
Lub-oil inlet temperature	–	High	–	*Y*	
Speed of turbocharger	Speed	High	–	–	Applicable to Class B and C turbochargers (refer to 9.6.2, Ch.9, Pt.3)

Item	LCS		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm			
1	2	3	4	5	6
Oil mist concentration in crankcase (or main, crank bearing temperature or lubricating oil outlet temperature of the above bearing or other equivalent devices)	–	High	a	G_a	Applicable to diesel engines specified in 9.7.6, Ch.9, Pt.3; one oil mist detector for each engine having two independent outputs for initiating the alarm and shutdown would satisfy the requirement for independence between alarm and shutdown systems
Flow rate of cylinder lubricator. Each apparatus	–	Small	–	*Y*	Required if necessary for safe operation of the engines
Pressure of cooling seawater	Pressure	Low	–	*Y*	
Cylinder cooling water pressure or flow	Pressure or flow	Low	–	*Y*	
Cylinder cooling water outlet temperature	Temp.	High	–	*Y*	
Level of cylinder cooling water in expansion tank	–	Low	–	*Y*	
Starting air pressure	Pressure	Low	–	*Y*	
Control air pressure	Pressure	Low	–	*Y*	
Exhaust gas temp. after each cylinder	Temp.	High	–	*Y*	For diesel engines having a power of more than 500 kW per cylinder only
Speed	–	Overspeed	a	G_a	See 9.7.10.3 of Pt.3
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic pressure)	Electrical, pneumatic and hydraulic pressure	Loss	–	*Y*	Indication of voltage may be replaced by indicating lamp
10 Gas turbines driving propulsion generators					
Fuel oil pressure or flow	Pressure or flow	Low	–	*Y*	
Fuel oil temperature or viscosity	Temp. or viscosity	Low or high	–	*Y*	Only for heavy oil
Lub-oil inlet pressure to gas turbine and gearing	Pressure	Low	–	*Y*	
		Excessively low	a	G_a	
Lub-oil inlet temperature to gas turbine and gearing	Temp.	High	–	*Y*	
Turbine main bearing temperature	Temp.	High	–	*Y*	
Lub-oil filter differential pressure	–	Great	–	*Y*	
Level in lub-oil circulating tank	–	Low	–	*Y*	For gravity and circulating oil tanks
Coolant pressure or flow	–	Low	–	*Y*	
Coolant temperature	Temp.	High	–	*Y*	
Level in fuel oil tank for ignition and starting	–	Low	–	*Y*	When it is replenished automatically, high and low level alarms are to be fitted
Gas turbine ignition	–	Failure	a	G_a	
Combustion chamber flame	–	Extinguished	a	G_a	
Exhaust gas temperature	Temp.	High	a	G_a	
Gas turbine vibration	–	Excessive	a	G_a	
Axial displacement of turbine rotor	–	Great	a	G_a	Automatic shutdown not required if fitted with roller bearings
Gas turbine speed	–	Overspeed	a	G_a	
Power supply for control-safety-alarm systems (electrical, pneumatic and hydraulic	Electrical, pneumatic and	Loss	–	*Y*	Indication of voltage may be replaced by indicating lamp

Item	LCS		Mode of protective control action	Mode of alarm at BCS	Remark
	Display	Limit alarm

pressure)	hydraulic pressure				
11 Miscellaneous					
Overriding function	–	When overriding is initiated	–	*S*	
Automatic systems	–	Failure	–	*Y*	Including electric power fault

4.3.5 Requirements for automation of small ships with class notation BRC

4.3.5.1 For small ships of less than 500 gross tonnage with the class notation BRC, only group alarms activated by Mode a and Mode b protective actions as defined in Table 4.3.4.1 of this Section are to be provided in the BRC.

Section 1 GENERAL PROVISIONS

1.1.1 General requirements

1.1.1.1 This Chapter applies to the fire-fighting ships applying for one of the class notations listed in 1.1.2 below.

1.1.1.2 The fire-fighting ships intended to extinguish the following fires respectively are divided into Grades 1, 2 and 3 in this Chapter:

Fire-fighting ships of Grade 1 are for early stage fire-fighting;

Fire-fighting ships of Grade 2 are for large fire-fighting;

Fire-fighting ships of Grade 3 are for large or oil fire-fighting.

1.1.1.3 The fire-fighting ships are to comply with the requirements of this Chapter and in addition, the applicable requirements in other PARTs of the Rules and the requirements of ISC Rules for Materials and Welding.

1.1.1.4 The minimum requirements for fire-fighting ships of Grades 1, 2 and 3 are listed in Table 1.1.1.4.

List of Minimum Requirements for Fire-Fighting Ships Table 1.1.1.4

Equipment	Grade of fight-fighting ships			
	1	2		3
Minimum number of water monitors	2	3	4	4
Minimum discharge rate per monitor, in m^3/h	1200	2400	1800	2400
Minimum number of fire pumps	1	2		2
Minimum total pump capacity, in m^3/h	2400	7200		9600
Performance of water monitors: Minimum height of trajectory of jets of monitors above sea level, in m Minimum range of monitors jets, in m	 45 120	 70 150		 70 150
Minimum fuel capacity for simultaneous working of all water monitors, in h	24	96		96
Fixed foam fire-extinguishing system: Minimum number of foam monitors Minimum discharge rate per system, in m^3/h Time of continuous foam production, in min	 – – –	 – – –		 2 300 30
Mobile fire-fighting equipment: Portable foam generator Minimum foam capacity, in m^3/min Time of continuous foam production, in min	 – –	 100 30		 100 30
Fire hoses Number of hose connections each side of ship	 4	 8		 8
Number of fireman's outfits	4	8		8

1.1.1.5 Where it is necessary for fire-fighting ships to deviate from the requirements of this Chapter due to their specific missions such as geographical limitations or particular objects to be served, ISC may impose other requirements as appropriate on such ships. And individual requirements in this Chapter may also be relaxed subject to agreement of ISC.

1.1.2 Notations

1.1.2.1 For all grades of fire-fighting ships complying with the requirements in this Chapter, the following notations are to be granted respectively:

Fire-fighting ships of Grade 1: Fire-Fighting Ship 1;

Fire-fighting ships of Grade 2: Fire-Fighting Ship 2;

Fire-fighting ships of Grade 3: Fire-Fighting Ship 3.

1.1.2.2 For ships provided with a water spraying system complying with 1.3.1 of this Chapter for delivering efficient cooling water spraying over all the exposed vertical surfaces of the hull so as to enable the ship to approach the burning object for fire-fighting and/or rescue purposes, the notation of Water Spraying may be affixed to that mentioned in 1.1.2.1 of this Section.

1.1.3 Plans and documents to be submitted

1.1.3.1 In addition to those required in the relevant Chapters of the Rules, the following plans and documents are to be submitted for approval:

(1) Arrangement and specification of water monitor system (including capacity, range and jet trajectory of pumps and monitors);

(2) Plan of seating arrangements for water monitors;

(3) Arrangement of water spray systems (if provided);

(4) Arrangement and specification of fireman's outfits and air compressors;

(5) Arrangement and specification of searchlights;

(6) Plan of remote control system of monitors;

(7) Arrangement of hose connection positions and associated piping on each side of ship;

(8) Stability calculations for fire-fighting operations;

(9) Operation manual, including:

① detailed description of each fire-fighting system and equipment;

② instructions on use, test and maintenance of fire-fighting installations and equipment;

③ instructions on maneuvering of ship during fire-fighting.

1.1.3.2 In addition to the plans and documents required in the relevant Chapters of the Rules, the following documents are to be submitted for information:

(1) Particulars of the means of keeping the ship in position during fire-fighting operations;

(2) Estimation of fuel consumption during fire-fighting operations.

1.1.3.3 For fire-fighting ships of Grade 2 or Grade 3, in addition to the plans and documents required in 1.1.3.1 and 1.1.3.2, the following plans and documents are to be submitted for approval:

(1) For fire-fighting ships of Grade 2:

Arrangement and specification of mobile fire-fighting equipment;

(2) For fire-fighting ships of Grade 3:

① Arrangement and specification of mobile fire-fighting equipment;

② Plan of seating arrangements for foam monitors;

③ Arrangement and specification of foam systems;

④ Plan of remote control system of foam monitors.

1.1.3.4 Other plans and documents are to be additionally submitted for approval or for information where deemed necessary.

Section 2 BASIC REQUIREMENTS

1.2.1 Hull structure

1.2.1.1 The hull structure is to be strengthened if necessary to withstand the forces imposed by the fire-fighting systems when operating at their maximum capacity.

1.2.2 Stability

1.2.2.1 When all monitors are in operation at full capacity in the most adverse direction for the stability, the ship is to have satisfactory stability corresponding to the load conditions.

1.2.3 Maneuverability

1.2.3.1 The ships are to have side thrusters and propulsion machinery with sufficient power for adequate maneuverability during fire-fighting operations. However, if means are provided to keep the ship at a standstill during fire-fighting operations, side thrusters may not be provided.

1.2.3.2 Side thrusters (if any) and main propellers are to keep the ship at a standstill in calm waters at all combinations of capacity and direction of throw of the water monitors and foam monitors, and the most unfavourable combination is not to be more than 80% of the available propulsion force in any direction.

1.2.3.3 In order to prevent overloading during combined manoeuvring, means are to be provided for sending visual and audible alarms to the navigating bridge at 80% of the available propulsion power, and for automatically reducing the power at 100% of the available propulsion force, so as to prevent sudden or complete loss of power due to power overload.

1.2.3.4 A simple control system is to be provided for operating the main propulsion plant and side thrusters (if any) to adjust:

(1) the resultant thrust vector for the ship;

(2) the turning moment of the ship;

(3) the ship's heading.

1.2.4 Lighting

1.2.4.1 Two searchlights are to be provided to permit operations of the fire-fighting equipment at night.

1.2.4.2 The searchlights are to be capable of providing at a range of 250 m in clear atmospheric conditions a level of illumination of 50 lx within an area of not less than 11 m diameter. They are to be capable of being adjusted in the horizontal and vertical directions.

1.2.5 Fuel capacity and replenishment

1.2.5.1 The quantity of fuel oil for continuous fire-fighting operations at maximum required capacity is at least to comply with Table 1.1.1.4 of this Chapter.

1.2.5.2 The fuel capacity is to be additional to what is provided for normal operation of the ship, e.g. ship's propulsion.

1.2.5.3 Where necessary, consideration is to be given to the requirement that any fuel which may be required while the ship is operating on station can be safely received on board.

1.2.6 Operation manual

1.2.6.1 An approved operation manual is to be kept on board.

Section 3 PROTECTION AND FIRE-FIGHTING EQUIPMENT

1.3.1 Water spray systems

1.3.1.1 Where a fire-fighting ship is provided with a fixed water spray system, the system is to ensure a protection of all outside vertical areas of hull above waterline, including superstructures, deckhouses, seatings for water monitors and other fire-fighting equipment.

1.3.1.2 The water spray system is to have a capacity of at least 5 *l*/min per m^2 of the protected area which is internally insulated to A-60 class and at least 10 *l*/min per m^2 of other protected areas.

1.3.1.3 The pumping capacity is to be sufficient to supply simultaneously at the required pressure the sections which serve the maximum area exposed to radiant heat from a fire. Where the main fire pumps are used for this purpose, they are to be capable of operating this system, the water monitors and the hose stations simultaneously at the required pressure. A connection with an isolating valve is to be fitted between the piping system for the water monitors and the supply line for the water spray system.

1.3.1.4 The water spray system is to be divided into sections so that it will be possible to close down sections covering surfaces which are not exposed to radiant heat.

1.3.1.5 The nozzles of the water spray system are to be arranged to give an even distribution of water spray over the protected areas.

1.3.1.6 Deck scuppers and freeing ports are to be of sufficient area to ensure efficient drainage of water from decks and horizontal surfaces in all conditions when the water spray system is in operation.

1.3.1.7 Means are to be taken to ensure that necessary visibility from the navigation bridge and the remote-control station can be maintained during the water spray operations.

1.3.2 Water monitor systems

1.3.2.1 The minimum number of water monitors and their characteristics are to comply with Table 1.1.1.4 of this Chapter.

1.3.2.2 Arrangement of water monitor systems

(1) The water monitors are to be capable of being adequately adjusted in the vertical and horizontal directions to achieve the best target point of the jet, and to be so positioned that the jets will be unimpeded within the required range of operation.

(2) The water monitors are to be fitted on fixed and robust seatings so as to withstand the imposed forces from all modes of operation.

(3) At least two water monitors are to be equipped with a permanently fitted nozzle which can give solid or a spray jet as required.

1.3.2.3 Control of water monitors

In addition to the local manual operation, the monitors are to be capable of being activated and maneuvered by remote control from a protected position ensuring a good view of the monitors and of the area to be served.

1.3.2.4 Design and seating arrangements of water monitors

(1) The monitors are to be of robust construction to withstand shock loading when all the monitors are activated simultaneously.
(2) The seating arrangements of the monitors are to be of adequate strength for all modes of operation.
1.3.2.5 Pumps and piping systems
The pumps and piping systems are to comply with the relevant requirements of 1.3.4 of this Section.

1.3.3 Fixed foam monitor system
1.3.3.1 For fire-fighting ships of Grade 3, in addition to a water monitor system, a fixed low-expansion foam monitor system complying with this paragraph is to be provided.
1.3.3.2 Performance and capacity
(1) Two foam monitors are to be provided on board, each with a capacity not less than 300 m^3/h and a foam expansion ratio not more than 12:1.
(2) The arrangement and positions of the monitors and foam system are to be such that a height of throw at least 50 m above the sea level can be obtained, when both monitors are used simultaneously with maximum capacity.
(3) Sufficient foam concentrate is to be available for at least 30 min. of simultaneous operation of both monitors at maximum capacity. When determining the required capacity of the foam concentrate, the concentration ratio is to be assumed 5%.
1.3.3.3 Arrangement
(1) The foam generating system is to be of a fixed type, consisting of individual foam concentrate tank, foam-mixing unit and piping to the monitors.
(2) The system may be supplied by the pumps of water monitors. In such cases, the pump pressure is to be adjustable to ensure producing the maximum capacity of foam.
1.3.3.4 Control of foam monitors
In addition to the local manual control, foam monitors are to be provided with remote control which is to include the operation of the valves necessary for the control of both water and foam. The remote control of foam monitors is to be located at the same remote-control station for water monitors.
1.3.3.5 Design and seating arrangements of foam monitors
(1) The foam monitors are to be of robust construction.
(2) The seating arrangements of the monitors are to be of adequate strength for all modes of operation.
1.3.3.6 Pumps and piping systems
The pumps and piping systems are to comply with the relevant requirements of 1.3.4 of this Section.

1.3.4 Pumps and piping systems for water and foam
1.3.4.1 General requirements
(1) The pumps and piping systems conveying water and foam are not to be used for other services, except for the water spray system referred to in 1.3.1 of this Chapter and for the fire-extinguishing system of the ship itself.
(2) Where the pumps are used for the fixed water spray systems, the piping is to be independent from that serving the monitors.
(3) The piping system from the pumps to the water monitors is to be separate from the piping system to the hose connections required for the mobile fire-fighting equipment as specified in 1.3.5 of this Chapter.
(4) The piping systems are to have arrangements to avoid overheating of the pumps at low delivery rates.
(5) Suction lines are to be as short and straight as practicable. The design maximum water velocity in the suction lines is normally not to exceed 2 m/s.
(6) Piping between pumps and water monitors is to have a maximum design water velocity normally not exceeding 4 m/s.
(7) All piping from seawater inlets to water monitors is to be internally protected against corrosion. Piping exposed to the weather is to be protected also externally.
1.3.4.2 Arrangement of pumps
The pumps for fire-fighting systems and their prime movers are to be adequately protected, and so located that they will be easily accessible during operation and maintenance.
1.3.4.3 Seawater suctions
(1) Seawater suctions for the fire-fighting pumps are not to be used for other purposes.
(2) The seawater suction valve, pressure valve and the pump motor are to be operable from the same position. Valves with nominal diameter exceeding 450 mm are to be power actuated as well as manually operable.
(3) Starting of fire-fighting pumps when water inlet valves are closed is to be prevented either by an interlock system or by an audible and visual alarm.

(4) Seawater inlets and sea chests are to be of a design ensuring an even and sufficient supply of water to the pumps. The location of the seawater inlets and sea chests is to be such that the water supply is not impeded by the ship's motions or by the water flow to and from bow thrusters, side thrusters, azimuth thrusters or main propellers.
(5) Seawater suctions of the fire-fighting pumps are to be arranged as low as practicable to avoid icing.
(6) Seawater suctions are to be fitted with gratings having a free passage area not less than twice that of the sea suction valve, and efficient means are to be provided for cleaning the gratings in order to ensure the efficient operation of pumps.

1.3.5 Mobile fire-fighting equipment

1.3.5.1 For fire-fighting ships of Grade 2 or 3, the mobile fire-fighting equipment complying with 1.3.5.2 of this Section is to be provided.
1.3.5.2 High-expansion foam generator
(1) Where required in Table 1.1.1.4 of this Chapter, the mobile high-expansion foam generator is to be provided with a capacity not less than 100 m^3/min for fighting external fires.
(2) Foam-forming liquid is to be stored in portable containers of about 20 *l* individual capacities. The total capacity of foam-forming liquid is to be sufficient for 30 min of continuous foam production.

1.3.6 Fire Hoses

1.3.6.1 Hose stations are to be provided on each side of the ship in accordance with the number required in Table 1.1.1.4 of this Chapter.
1.3.6.2 Each hose station is to be provided with a hydrant, a hose and a nozzle capable of producing a jet or a spray and simultaneously a jet and a spray.
1.3.6.3 The hoses are in general to be 15 m in length and not less than 38 mm nor more than 65 mm in diameter.

1.3.7 Fireman's outfit

1.3.7.1 Fire-fighting ships are to be provided with fireman's outfit in accordance with Table 1.1.1.4 of this Chapter.
1.3.7.2 Each self-contained breathing apparatus is to have a capacity of at least 1,200 *l* of free air, and at least one spare air bottle is to be provided for each apparatus.
1.3.7.3 The fireman's outfit is to be stored in a safe position readily accessible from the open deck.
1.3.7.4 A suitable air compressor is to be provided for recharging the air cylinders. It is to be capable of recharging the cylinders used in the breathing apparatus of all the fireman's outfits required in Table 1.1.1.4 of this Chapter (excluding the spare air cylinders) within 30 min. The air quality in the recharged cylinders is to be suitable for human respiration.

CHAPTER 2 ADDITIONAL REQUIREMENTS FOR LIVESTOCK CARRIERS

Section 1 GENERAL PROVISIONS

2.1.1 Application

2.1.1.1 This Chapter applies to livestock carriers.

2.1.1.2 Livestock carriers complying with the requirements of this Chapter are eligible for the assignment of the notation: Livestock Carrier.

2.1.1.3 In addition to the provisions of this Chapter, livestock carriers are to comply with the applicable requirements for livestock carriers in other chapters of the Rules, ISC Rules for Materials and Welding and relevant requirements of the flag State Administration (if any).

2.1.2 Definitions

2.1.2.1 Livestock carrier refers to a sea-going steel ship constructed or adapted and used solely for the carriage of livestock cargoes. Livestock includes sheep, cattle, horses and pigs, etc.

2.1.2.2 Secondary power source refers to the source of power which may supply independent power for livestock service systems if the main source of power is out of action.

2.1.3 Plans and documents

2.1.3.1 In addition to the plans and documents as specified in relevant chapters of the Rules, the following plans and documents are to be submitted for approval:

(1) Arrangement of livestock pens and passageways;

(2) Constructions of livestock pens and passageways;

(3) Diagram of storage and distribution systems for fodder and water;

(4) Diagram of the water washing system;

(5) Diagram of the sewage drainage and discharge system;

(6) Arrangement of fire-fighting appliances in livestock spaces;

(7) Diagram of secondary power source system;

(8) Arrangement of secondary power sources spaces;

(9) Piping diagram related to secondary power sources.

2.1.3.2 The following plans and documents are to be submitted for information:

(1) Diagram of the ventilation system, with indication of the gross volume and calculations of air change rates of the enclosed spaces;

(2) Specifications of fire-fighting appliances;

(3) Estimation of fuel consumption of secondary source of power and estimation of time for restarting (restoration) of secondary source of power (if applicable).

Section 2 HULL STRUCTURE AND ARRANGEMENT

2.2.1 Hull structure

2.2.1.1 The structure of livestock carriers is to comply with the relevant requirements of Chapter 2, PART TWO of the Rules.

2.2.1.2 Where superstructure deck is strength deck (contributing to the longitudinal strength), the thickness of deck plating, excluding that of the forecastle, is to comply with the requirements of 2.17.5.4 in Chapter 2 of PART TWO and the buckling strength requirements in respect to longitudinal strength of Section 2, Chapter 2 of PART TWO, but not less than 6 mm.

2.2.1.3 Where superstructure deck is strength deck (contributing to the longitudinal strength), the framing of superstructure deck is to comply with the relevant requirements of Section 8, Chapter 2 of PART TWO and the buckling strength requirements in respect to longitudinal strength of Section 2, Chapter 2 of PART TWO.

2.2.2 Livestock arrangement and protection of livestock

2.2.2.1 The livestock is to be kept in pens. The dimensions of these pens are to be suitable for the livestock carried and are to comply with the requirements in Table 2.2.3.5.

2.2.2.2 Arrangements for protecting the livestock from injury, avoidable suffering and exposure to weather, sea or heat source are to be provided.
2.2.2.3 Livestock may not be carried or loaded for carriage on or in any part of a ship where the livestock, livestock fittings, livestock equipment or arrangements may:
(1) obstruct access to any accommodation space or working space necessary for the safe running of the ship, or the means of egress from any hold or underdeck space;
(2) interfere with life-saving or fire-fighting appliances;
(3) interfere with the tank sounding equipment or bilge pumping;
(4) interfere with the operation of closing appliances;
(5) interfere with the operation of freeing ports;
(6) interfere with the lighting or ventilation of other parts of the ships;
(7) interfere with the proper navigation of the ship.
2.2.2.4 If the casing or bulkhead of an engine room, boiler room or heated fuel tank forms the boundary of a space in which livestock is to be carried, appropriate heat insulation is to be provided.
2.2.2.5 The following measures are to be taken to avoid hurt to livestock from exposed steel structure during the movement of livestock:
(1) protective boards are to be fitted on both sides of upper and lower passageways;
(2) protective boards are to be fitted on pens adjacent to the bulkhead with stiffeners or similar structures.

2.2.3 Livestock pen, means of access for livestock and livestock deck

2.2.3.1 A ramp or other suitable means of access appropriate to the species, is to be provided for the loading or unloading of livestock. It is to be so erected as to prevent any gap occurring between it and the ship and is to be set at a gradient suitable for the species to be loaded or unloaded.
2.2.3.2 A means of access is to be fitted with:
(1) side panels free of protrusions and of sufficient strength and height to prevent escape of livestock;
(2) a walking surface of battens suitable for the species; and
(3) a closing arrangement.
2.2.3.3 If a means of access is part of the ship's equipment, it is to be designed to support a uniformly distributed load over the walking surface not less than the values specified in Table 2.2.3.3.

Table 2.2.3.3

Species	Load (N/m^2)
Cattle and horses	4700
Sheep, goats and pigs	2400

2.2.3.4 The permissible tensile stress for material used in the construction of a means of access is specified in Table 2.2.3.4.

Table 2.2.3.4

Material	Permissible tensile strength
Steel	$R_{eH}/2$
Aluminum	$R_{p0.2}/2$
Other	To be specially considered by ISC

2.2.3.5 Livestock pen and means of access for livestock are to comply with the requirements of Table 2.2.3.5.

Limits for pens and passageways of sheep and pigs **Table 2.2.3.5(1)**

Maximum breadth	4.5 m
Minimum breadth	2.0 m
Maximum length	Not more than twice the breadth
Minimum length	Not less than the breadth
Maximum clear floor area within pen	40.5 m^2
Minimum clear height within pen	1.1 m
Maximum clear vertical distance between rails	0.3 m
Maximum clear vertical distance below bottom edge of lowest rail of pen installed at deck level	0.2 m
Maximum clear vertical distance below bottom edge of lowest rail of pen not installed at deck level	0.05 m
Minimum height of top edge of uppermost rail above pen floor	0.9 m
Minimum width of adjacent passageway clear of receptacles and any other obstructions	0.55 m

Limits for pens and passageways of cattle **Table 2.2.3.5(2)**

Maximum breadth	4.5 m
Minimum breadth	2.1 m
Minimum length	2.3 m
Maximum clear floor area within pen	21 m^2
Maximum height of top edge of lowest rail above pen floor between pens	0.6 m
Minimum clear height within pen	1.8 m if a mechanical ventilation system is provided 2.3 m in any other case
Minimum width of adjacent passageway, measured clear between rails, when pens are on both sides of the passageway and cattle are loaded and discharged through the pens	1.0 m
Minimum width of adjacent passageway, measured clear of any fixed structure, fittings, receptacles or obstruction (eg pillars, feed chutes, fixed fodder or water troughs), when pens are on both sides of the passageway and cattle are loaded and discharged through the pens	0.7 m
Minimum width of adjacent passageway, measured clear of any fixed obstructions, when pens are on both sides of the passageway and cattle are loaded and discharged through the passageway	1.0 m
Minimum width of adjacent passageway measured clear from rails, when pens are on one side only of the passageway	0.75 m

Limits for stalls, pens and passageways of horses **Table 2.2.3.5(3)**

Maximum clear length within stall		2.5 m
Minimum clear length within stall		2.3 m
Minimum clear passage	(1) between 2 rows of stalls and bounded by the front rails	1.7 m
	(2) between 2 rows of stalls and bounded by front and back rails	1.2 m
	(3) in any other case	1.0 m
Minimum clear breadth within stall	(1) if the stall is aligned athwartships	0.7 m
	(2) if the stall is aligned fore and aft	0.9 m
Height of uppermost front, back and side rail from floor to top edge		1.15 m
Height of lowest front, back and side rail from floor to top edge		0.75 m

Note: Pens dedicated for the carriage of other livestock are to be submitted to ISC for special consideration.

2.2.3.6 Livestock pens are to be designed based on the load determined by the application of the following formula:

$$F = \alpha b\left[0.574 + 0.0252\left(Z + \gamma\right)\right] \quad \text{N/m}$$

where: α — coefficient, taken as 1668 for sheep or pigs and 3336 for cattle or horses;
b — maximum breadth of pen, in m;
Z — the vertical distance from the ship's minimum draught water-line to the pen floor;
γ — coefficient, taken as 0.5 for sheep or pigs and 0.75 for cattle or horses.

Load bearing areas are:
for sheep and pigs: uniformly distributed up to the rail the centre of which is at a height of not more than 0.9 m above the pen floor;
for cattle and horses: uniformly distributed up to the rail the centre of which is at a height of not more than 1.40 m above the pen floor.

2.2.3.7 Livestock pen floors or platforms are to be designed according to the following formula with the load uniformly distributed in any two-thirds of the area of the pen:

$$P = \beta\left[1 + ((0.094 - 0.00035L)\,y + (7.4 - 0.016L))/d\right] \text{ N/m}^2$$

where: β — coefficient, taken as 2500 for sheep or pigs and 5000 for cattle or horses;
d — minimum draught of the ship, in m;
y — longitudinal distance from the midpoint of the pen to amidships, in m;
L — length between the perpendiculars of the ship, in m.

2.2.3.8 The permissible stresses of livestock pens and floors are given in Table 2.2.3.8.

Table 2.2.3.8

Material	Permissible tensile stress	Permissible shear stress
Steel	$0.75R_{eH}$	$0.375\,R_{eH}$
Aluminium	$0.75\,R_{p0.2}$	$0.375\,R_{eH}$

Other	To be specially considered by ISC	To be specially considered by ISC

2.2.4 Means of egress and access for persons

2.2.4.1 Each space in which livestock is carried is to be provided with no fewer than two means of egress widely separated and giving access to an open deck.

2.2.4.2 Access to a livestock space for persons is to be safe and, if combined with a ramp used for moving livestock between decks, is to be separated from the livestock ramp by protective fencing.

2.2.4.3 A pen, stall or similar fitting is to be provided with a means of access for persons with a secure closing arrangement having a structural strength equivalent to the strength of that part of the pen, stall or fitting.

2.2.4.4 If access is required between a vessel's side and a pen, stall or similar fitting for the purposes of the safe and proper operation of the vessel, a passageway is to be provided that has a clear width of not less than 750 mm between the vessel's rail or bulwark and the rails or receptacles of the pen, stall or fitting, except that obstructions outside the pen rails may reduce the passageway measured from the vessel's rail to 550 mm.

2.2.4.5 Where it is necessary for persons to be on a means of access during the movement of livestock, a passage of not less than 550 mm width is to be provided, which is to be:

(1) fenced to a height of not less than 1 m and with an intermediate horizontal rail approximately 550 mm above the walking surface; and

(2) fitted with treads at suitable stepping distances.

2.2.4.6 The passageways in spaces for the carriage of livestock are to have a minimum clear height of 2.0 m.

Section 3 STABILITY

2.3.1 General requirements

2.3.1.1 The stability of livestock carriers is to comply with the requirements of this Section or relevant requirements of the flag State Administration.

2.3.1.2 The stability of livestock carriers is to comply with the requirements for cargo ships in Sections 9 and 10 of Chapter 1, PART TWO of the Rules.

2.3.2 Additional requirements for stability

2.3.2.1 The effects of the shift of livestock and fodder in pellet form (if any) and the effect of wind are to be taken into account for intact stability of livestock carriers. The following criteria are to be complied with for livestock carriers under intact condition:

(1) The angle of heel is not to exceed 10 degrees due to the effect of wind.

(2) The residual area *A* is to comply with the following requirements, taking into account the effects of the shift of livestock and fodder in pellet form and the effect of wind, as illustrated in Figure 2.3.2.1 below:

$$A \geq 0.018 \text{ m•rad} + 0.2A_{(A+B)}$$

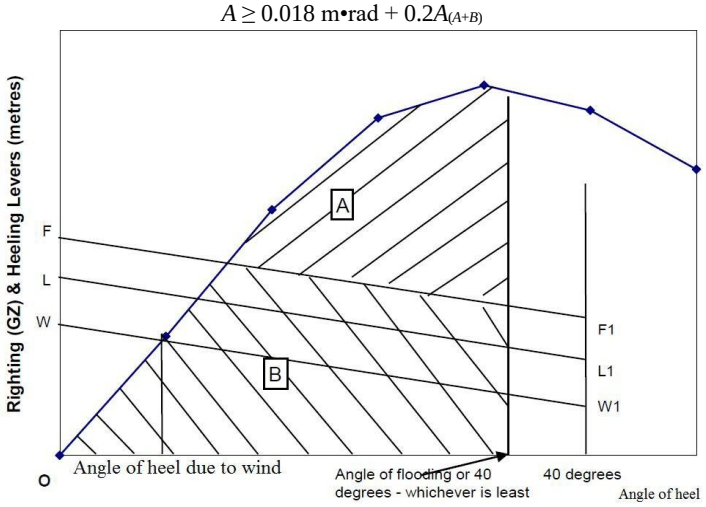

Figure 2.3.2.1 Rolling Criteria

where: $A_{(A+B)}$ is the sum of area *A* and area *B* under the righting lever curve, as illustrated in Figure 2.3.2.1. Definitions in Figure 2.3.2.1 are as follows:

OW — the heeling lever at 0° due to wind;
WW_1 — the heeling lever curve due to wind;
WL — the heeling lever at 0° due to the shift of livestock;
LL_1 — the heeling lever curve due to the combined effects of wind and the shift of livestock;
LF — the heeling lever at 0° due to the effect of shift of fodder;
FF_1 — the heeling lever curve due to the combined effects of wind and the shift of livestock and fodder;
θ — the angle of heel due to wind.

Note: If fodder is not pellet feed carried in bulk, the heeling lever due to shift of fodder will be zero.

(3) The heeling lever due to the effect of wind is to be determined according to the following requirements:

① The heeling lever due to the effect of wind at 0° is to be given by $OW = \frac{PAH}{\Delta}$,

where: Δ — displacement, in t;
P — wind pressure, 504 pa;
A — lateral area of the vessel above the waterline, in m^2;

H — vertical distance between the centroid of the lateral area of the vessel above the waterline and the centroid of the vessel's underwater lateral area. For most vessels the vertical position of the centroid of the underwater lateral area may be taken as half the draft to the underside of the keel at amidships.

② The heeling lever due to the effect of wind at 40° is to be given by 0.8 (heeling lever due to the effect of wind at 0°).

③ The heeling lever curve is to be taken as a straight line joining the heeling lever at 0° and the heeling lever at 40°.

(4) The heeling lever due to the shift of livestock is to be determined according to the following requirements:

① The heeling lever due to the shift of livestock at 0^o is to be given by $\frac{m \cdot C}{f \cdot \Delta}$,

where: m — average mass of livestock to be carried on the intended voyage, in t;
f — floor area required per head of average mass of the livestock to be carried on the intended voyage, in m^2;

C — livestock shift constant, $C = \frac{1}{6}\sum lb^2$, where l is length of each pen, in m; b is breadth of each pen, in m. For vessels with uniform breadth of pens, the livestock vessel constant becomes: 1/6 (breadth of pen × total floor area of pens). For vessels with varying breadths of pens, the largest breadth may be used and the livestock shift constant becomes: 1/6 (maximum breadth of pen × total floor area of pens).

② The heeling lever due to the shift of livestock at 40° is to be given by 0.8 (heeling lever due to the shift of livestock at 0°).

③ The heeling lever curve is to be taken as a straight line joining the heeling lever at 0° and the heeling lever at 40°.

(5) The heeling lever due to the shift of fodder is to be determined according to the following requirements:

① The heeling lever due to the shift of fodder at 0° is to be given by $\frac{M_f}{s \cdot \Delta}$,

where: M_f — the sum of the shift moment of each compartment, where the shift moment of each compartment is to be given by 0.044 lb^3, where: l is the maximum length of the compartment; and b is the maximum breadth of the compartment, in m. The use of volumetric shift moments for the fodder, where the surface is assumed to take up an angle of slope of 15° to the horizontal for full compartments and 25° to the horizontal for partly filled compartments, is an acceptable alternative method to obtain the total shift moment of fodder;

s — stowage factor (the volume of fodder in pellet form per unit weight).

② The heeling lever due to the shift of fodder in pellet form carried in bulk at 40° is to be given by 0.8 (heeling lever due to the shift of fodder at 0°).

③ The heeling lever curve is to be taken as a straight line joining the heeling lever at 0° and the heeling lever at 40°.

Section 4 PROVISION OF LIVESTOCK SERVICES

2.4.1 General requirements

2.4.1.1 Facilities or systems providing daily services for livestock are to be fitted in livestock spaces and these facilities or systems intended for:

(1) the supply of food, water and fresh air to the livestock;

(2) the cleaning of the livestock spaces;

(3) the draining and outside discharging of the sewage effluents produced by the livestock.

2.4.1.2 In addition to the provisions of this Section, the piping is to comply with the applicable requirements of Chapter 2 and Chapter 3, PART THREE of the Rules.

2.4.2 Ventilation system

2.4.2.1 An enclosed space for the carriage of livestock is to be provided with a mechanical ventilation system of sufficient capacity to change the air of that space in its entire volume as follows:

(1) if the minimum clear height of the space is 2.30 m or more, not less than 20 changes per hour;

(2) if the minimum clear height of the space is 1.80 m, not less than 30 changes per hour; and

(3) if the minimum clear height of the space is between 2.30 m and 1.80 m, at a rate proportional to those specified above. This may be obtained by linear interpolation.

For the purposes of this paragraph, the volume of an enclosed space includes all that space contained between the vessel's side plating, bulkheads, tank top or decks enclosing the space, less the volume of any tanks or trunks that are airtight within the space and no deduction is to be made in respect of space occupied by livestock, pens or other livestock fittings.

2.4.2.2 A space for the carriage of livestock that is not enclosed is to be provided with a mechanical ventilation system if:

(1) the space, being a structure having an arrangement of pens on more than one deck level, has a breadth greater than 20 m; or

(2) because of a partial enclosure of the space, the natural ventilation is restricted.

The capacity of ventilation system is to comply with the requirements in paragraph 2.4.2.1.

The volume of a space that is not enclosed referred to in this paragraph includes all that space contained between the extremities of a pen structure including passageways on the outboard sides or ends of the structure, less the volume of any tanks or trunks that are airtight within the pen structure and no deduction is to be made in respect of space occupied by livestock, pens or other livestock fittings.

2.4.2.3 A mechanical ventilation system is to distribute air so as to ensure that the whole of each livestock space is efficiently ventilated.

2.4.2.4 Ventilation circuits are to be supplied by at least two independent fans of such a capacity as to maintain the ventilation of all the spaces as required by 2.4.2.1 and 2.4.2.2 with one fan out of action. Notwithstanding the above provisions, if a mechanical ventilation system is provided with adequate spare parts, the provision of only one fan is acceptable. Adequate spare parts are to be interpreted as including for each type of fan: one set of bearings; one rotor or impeller; and one complete motor.

2.4.2.5 Electrical supplies from both main and secondary sources of power are to be supplied to each group starter panel, with both supplies being as widely separated as practicable and neither passing through any space containing any part of the other source of power. Interlocks at each group starter are to prevent simultaneous supply by both sources of power.

2.4.2.6 If two or more independent fans are fitted in the ventilation piping of each space, fan group starter panels are to be located in at least two locations, with the operation of fans from either panel being able to effectively ventilate the required livestock spaces.

2.4.3 Fodder and Water arrangements

2.4.3.1 Spaces intended for livestock (including pens, stalls or similar fittings) are to be provided with receptacles for feeding and watering the animals concerned.

2.4.3.2 The receptacles are to be capable of containing at least 33 per cent of the daily allowance of fodder and water for the number of animals contained in the space (pen, stall or similar fitting) except where the fodder or water is provided by an automatic system.

2.4.3.3 A receptacle provided in accordance with 2.4.3.1 and 2.4.3.2 above is to be:

(1) suitable for the species of livestock;

(2) readily accessible to the livestock;

(3) capable of being serviced from outside the pen, stall or other fitting;

(4) so installed as to not impede ventilation; and

(5) so constructed and positioned, that fodder dust is not disturbed by the flow of ventilation.
2.4.3.4 If the fodder distribution system is dependent on electric power, the system is to be capable of being powered by both the main and secondary sources of supply.

2.4.4 Fresh water system

2.4.4.1 All livestock spaces are to be provided with fresh water service.
2.4.4.2 The fresh water system is to include one main supply pump and one standby pump, of a capacity sufficient to continuously supply fresh water to the livestock.
When the water supply system is not automatic, the standby pump may be replaced by a portable pump ready to be connected to at least one fresh water tank.
2.4.4.3 If the fresh water system is dependent on electric power, it is to be powered by both the main and secondary sources of power and can continue to operate despite a fire or other casualty in the space containing the main source of power. One pump may be located in the space occupied by the main source of power and supplied by that source of power. The other is to be able to maintain supply despite a fire or other casualty affecting the space occupied by the main source of power.
2.4.4.4 When the water supply is automatic, water receptacles are to be fitted with means of automatic water level control and devices to avoid the return of water from the receptacle to the fresh water tank.
2.4.4.5 The fresh water system serving the livestock spaces is to be totally independent from the fresh water system serving the spaces intended for the crew.

2.4.5 Water washing system

2.4.5.1 A water washing system is to be provided with appropriate connections to wash the livestock spaces.

2.4.6 Drainage and discharge of sewage

2.4.6.1 Each space intended for the livestock is to be fitted with a pipe or gutter of sufficient size to drain the sewage and the washing effluents.
2.4.6.2 Drainage arrangements are to be such that fluids drained from a pen are as far as practicable kept clear of other pens and associated working and access spaces.
Where necessary, drainage gutters and upper parts of the draining pipes are to be covered by a strainer plate. In addition, drainage pipelines are to be so arranged that the drainage system can still be used with the ship's trim by bow or stern.
2.4.6.3 The drainage system serving the livestock spaces is to be independent from any piping system serving the other spaces of the ship, and in particular from the bilge system.
2.4.6.4 The pipes and other components of the draining system are to be made of a material resistant to the corrosion due to the effluents.
2.4.6.5 Essential drainage tanks, wells and the top of drainage pipes in a vessel are to be accessible from outside livestock pens for the purpose of inspection and cleaning.
2.4.6.6 Pumps and ejectors serving the drainage tanks or wells are to be capable of conveying semi-solid matter.
2.4.6.7 All electrical equipment fitted to meet the requirements of 2.4.6 are to be capable of being operated by both the primary and the secondary sources of power.

Section 5 FIRE-FIGHTING APPLIANCES

2.5.1 Fire hydrants and fire hoses

2.5.1.1 The number and position of the hydrants are to be such that at least two jets of water not emanating from the same hydrant may reach any part of the spaces intended for the livestock. At least one of these jets is to be from a single length of hose without the necessity for hoses to pass over or through pens.
2.5.1.2 A fire hose is to be provided in an enclosed space for each hydrant and in any other space or on a deck for each 50 m length, or part thereof, of space or deck.
2.5.1.3 Each fire hose is to be provided with the necessary connections and a nozzle capable of directing water in the form of a spray and a jet.
2.5.1.4 Each hose is to be capable of being connected to any hydrant and to any other hose (other than hydrants and hoses within the engine room or accommodation spaces).
2.5.1.5 Fire hoses are to be located in conspicuous locations, near the hydrants and close to the entrances or access to the spaces.

2.5.2 Additional fire-fighting means

2.5.2.1 Livestock structures, including livestock decks and containment structures but excluding livestock services such as water pipes and feed troughs, are to be constructed of non-combustible materials.

2.5.2.2 If hay or straw is carried or used in a livestock space, one of the following fire-fighting means is to be provided:

(1) a fixed water fire-fighting system, or

(2) portable water extinguishers spaced not more than 18 m apart, one of which being positioned at the entrance of the space concerned.

2.5.2.3 Where electrical equipment other than that referred to in Section 6 of this Chapter is located in an enclosed livestock space, suitable fire-fighting means are to be provided in this respect.

Section 6 ELECTRICAL EQUIPMENT

2.6.1 General requirements

2.6.1.1 In addition to the applicable requirements of PART FOUR of the Rules, electrical equipment of livestock carriers is to comply with the provisions of this Section.

2.6.2 Sources of electrical power for livestock carriers

2.6.2.1 The main source of power is to meet the following:

The main source of power as specified in 2.1.1.1 of Chapter 2, PART FOUR of the Rules is to be provided and all electrical auxiliary services (including livestock services) necessary for maintaining the livestock carrier in normal operational and habitable conditions will be ensured without recourse to the emergency source of electrical power.

2.6.2.2 The secondary source of power is to meet the following requirements:

(1) The secondary source of power is to be located in a space that is not contiguous with any space containing the main source of power or part thereof, and be independent of any services provided from or through any such space. In case of a fire or other casualty in any space containing the main source of power or any part thereof, the secondary source of power must be capable of supplying power to livestock services for a period of 72 h.

(2) The prime mover of secondary source of power is to be capable of supplying power to the system within 30 min in the failure of main source of power. The prime mover may be started by an effective arrangement powered by an independent source of energy or the emergency source of power complying with the requirements of paragraphs 1.1, 1.4 and 2 of SOLAS regulation II-1/43.

(3) Instructions are to be provided for the changeover between main and secondary sources of power and vice-versa. A copy of such instructions is to be posted in the space containing the livestock source of power, and is to be readable under the emergency lighting required by SOLAS regulation II-1/43.2.2. The instructions are to detail, among other things, starting method, switchboard changeover and electrical supply changeover to livestock services.

(4) Cables of secondary source of power are to be kept away from cables of main source of power in so far as practicable and generally they do not pass through the same space.

2.6.3 Lighting

2.6.3.1 Livestock spaces, passageways between pens and access routes between or to those spaces are to be adequately lit.

2.6.3.2 An emergency lighting system that is automatically activated on the failure of the main electrical installation is to be provided in all parts of a vessel where livestock is carried, passageways between pens and access routes between or from those parts, and is to be capable of giving a level of illumination in all passageways and access routes for a continuous period of not less than 15 min. The lamp casings on light fittings for the emergency lighting system are to be painted red for ease of identification.

2.6.3.3 If fixed lighting is provided in a part of a vessel above the uppermost continuous deck, that lighting is to be capable of being controlled from the navigating bridge.

2.6.3.4 Light fittings is to be of sufficient strength and fitted with protective sheathing outside to resist damage by livestock and placed beyond possible contact by livestock.

2.6.4 Electrical equipment for use in dust laden atmospheres

2.6.4.1 Electrical equipment and cables installed in areas where flammable dusts may be present (such as spaces used for the storage or handling of bulk fodder) are to comply with the requirements of 2.18.3.2 of Chapter 2, PART FOUR of the Rules.

2.6.4.2 Lighting, or power points for portable lighting, in a space used for carriage of fodder in bulk, are to be controlled by switches situated on the navigating bridge or at the fodder-handling machinery control station and indicator lights are to be provided to show when power is supplied to the lighting or power points.

CHAPTER 3 ADDITIONAL REQUIREMENTS FOR OIL RECOVERY SHIPS

Section 1 GENERAL PROVISIONS

3.1.1 General requirements

3.1.1.1 The requirements of Sections 1 to 5 of this Chapter apply to steel ships equipped for the recovery of oil floating on the sea with a flash point not exceeding 60℃ (closed-cup test) and a Reid vapour pressure below atmospheric pressure, as required for the class notations in paragraphs 3.1.2.1 and 3.1.2.2.

The requirements of Section 6 of this Chapter apply to steel ships equipped for the recovery of oil floating on the sea with a flash point exceeding 60℃ (closed-cup test) and a Reid vapour pressure below atmospheric pressure, as required for the class notation in paragraph 3.1.2.3.

3.1.1.2 The ship is to be capable of the following operations at a safe distance from the source of oil spill:

(1) recovery of floating oil from the surface of the sea;

(2) handling, storage and transportation of the recovered oil.

3.1.1.3 The other auxiliary ships associated with operations of oil recovery ships may be dealt with by referring to this Chapter.

3.1.2 Class notations

3.1.2.1 Oil recovery ships equipped with means for the recovery and discharge of oil as well as with tanks for storing the recovered oil and complying with the requirements of Sections 1 to 5 of this Chapter will be assigned the class notation Oil Recovery Ship with Cargo Tank.

3.1.2.2 Oil recovery ships without tanks for storing the recovered oil equipped with means for the recovery, but not for discharge of oil and complying with the requirements of Sections 1 to 5 of this Chapter will be assigned the class notation Oil Recovery Ship without Cargo Tank.

3.1.2.3 Oil recovery ships equipped with means for the recovery of oil and complying with the requirements of Section 6 of this Chapter will be assigned the class notation Oil Recovery Ship not suitable for products with a flash point of 60℃ and less.

3.1.3 Definitions

3.1.3.1 Oil recovery ship means a steel ship specially or also engaged in the recovery of oil floating on the sea.

3.1.3.2 Gas-hazardous zone means an area in which flammable or explosive gas or vapor is liable to accumulate to a dangerous concentration. The gas-hazardous zones may be divided into the following categories:

(1) Hazardous zone of Category 0 means an area in which the mixture of flammable or explosive gas or vapor with air exists continuously or for long time.

(2) Hazardous zone of Category 1 means an area in which the mixture of flammable or explosive gas or vapor with air may occur during normal operation.

3.1.3.3 Source of oil spill means the source from which the oil floating on the sea originates, e.g. from an oil tanker, a submarine oil pipeline or an offshore drilling unit.

3.1.4 Division of gas-hazardous zones and safe areas

3.1.4.1 The following areas or spaces of oil recovery ships are to be regarded as gas-hazardous zones:

(1) Hazardous zones of Category 0:

① recovered oil tanks;

② the interiors of piping systems and containers of the containment system for recovered oil.

(2) Hazardous zones of Category 1:

① cofferdams or other spaces adjacent to any recovered oil tank (except for 3.2.2.6);

② enclosed or semi-enclosed spaces in which pipe flanges, valves, hoses, pumps and other equipment for handling of recovered oil are located;

③ spaces including semi-enclosed spaces on open deck within a 3 m radius of the separator, the hoses and valves used for oil recovery, the openings of recovered oil tanks and the openings of spaces within the hazardous zones of Category 1 such as recovered oil pump rooms or cofferdams. In addition, the relevant provisions for venting outlets of covered oil tanks are to be considered (refer to 3.3.3.2 of this Chapter);

④ space on open deck above recovered oil tanks, extending 3 m respectively fore and aft of this area to a height of 2.4 m;

⑤ any enclosed space outside a recovered oil tank, through which recovered oil piping passes or in which such piping terminates, may be excluded, provided that ventilation is fitted as specified in 3.2.5.4 of Section 2;

⑥ enclosed or semi-enclosed spaces which can be entered directly from hazardous zones of Category 1 (without air lock) or which have openings into hazardous zones of Category 1 may be excluded, provided that ventilation is fitted as specified in 3.2.5.4 of Section 2.

3.1.4.2 The areas outside the above-mentioned gas-dangerous zones are safe areas.

3.1.5 Plans and documents

3.1.5.1 The relevant plans and documents as specified in the relevant chapters of the Rules and in addition, the following ones are to be submitted for approval:

(1) General arrangement of equipment for oil recovery operations;

(2) Details of access doors (including air locks) and openings used in normal recovery operations and not fitted with gastight sealing;

(3) Details of access doors and openings closed gastight in oil recovery operations;

(4) Details of arrangement and capacity of recovered oil tanks;

(5) Division of gas-hazardous zones;

(6) Drawing of power system of the equipment used for oil recovery operations;

(7) Details of arrangement of piping, pumping and handling systems for recovered oil;

(8) Arrangement of venting system of recovered oil tank;

(9) Arrangement of electrical equipment in gas-hazardous zones;

(10) Operating manual (see Section 5 of this Chapter);

(11) Other plans and documents as deemed necessary.

Section 2 CONSTRUCTION AND FIRE SAFETY

3.2.1 Hull structures

3.2.1.1 The structures of oil recovery ships are to comply with the relevant requirements of Chapter 2, PART TWO of the Rules.

3.2.1.2 For integral recovered oil tanks, the thickness of the plane oiltight bulkhead plating is to comply with the requirements of 3.2.1.3 and 3.2.1.4, and other structural members of bulkhead are to comply with the relevant requirements of Chapters 5 and 6, PART TWO of the Rules.

3.2.1.3 The thickness t of the plane oiltight bulkhead plating of integral recovered oil tanks is not to be less than that obtained from the following formula:

$$t = 3.75s\sqrt{h} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, from lower edge of the plate in a strake to the tank top, but not less than $0.4D$.

3.2.1.4 The thickness t of the plane oiltight bulkhead plating of integral recovered oil tanks is also to comply with the following requirements:

(1) Where vertical stiffeners are fitted on the bulkhead:

$t \geq s/86$ mm, for the upper 3/4 of the bulkhead

$t \geq s/74$ mm, for the lower 1/4 of the bulkhead.

(2) Where horizontal stiffeners are fitted on the bulkhead:

$t \geq s/98$ mm, for the upper 3/4 of the bulkhead

$t \geq s/84$ mm, for the lower 1/4 of the bulkhead

where: s — spacing of stiffeners, in mm.

3.2.2 Arrangement of recovered oil tanks

3.2.2.1 Any tanks, which are also intended for other purposes and will not be utilized during oil recovery operations, are to be arranged so that recovered oil cannot be transferred to them inadvertently.

3.2.2.2 The position of tanks for recovered oil is to satisfy the following requirements:

(1) they are to be located outside the accommodation and machinery spaces;

(2) they are not to be located below the accommodation and machinery spaces;

(3) they are to be located forward or aft of the accommodation and machinery spaces of category A.

3.2.2.3 Except where permitted by 3.2.2.6, tanks for recovered oil are to be separated from accommodation and machinery spaces by cofferdams. Oil fuel tanks, settling tanks, tanks for ballast water or anti-pollution liquid, enclosed spaces where oil recovery handling equipment is stored, pump rooms for recovered oil and dry compartments other than accommodation spaces may be considered as a cofferdam. When oil fuel tanks or settling tanks are used as cofferdams, only one common boundary can be provided between each oil fuel tank or settling tank and the tank for recovered oil. The continuous butt welding is to be used for the bulkhead plating of the common boundary. Full penetration welding is to be used for the fillet weld at the connection of the bulkhead to the deck.

3.2.2.4 Cofferdams are to be at least one frame spacing in length (600 mm minimum) and are to cover the whole area of the boundary under consideration.

3.2.2.5 The height of tanks for recovered oil is not to be less than 1.5 m. Internal obstructions in the tanks are to be avoided to ensure a full flow of recovered oil. Adequate drainage openings are to be provided to ensure free flow of residues to assist in cleaning and gas freeing on completion of recovery operations. Any coating in the walls of tanks for recovered oil is to be of an oil and dispersion resistant type.

3.2.2.6 Where cofferdams are impractical to arrange in accordance with the requirements of 3.2.2.3 on board, any tank adjacent to other machinery spaces (except for machinery spaces of category A) or pipe tunnel may be accepted for storage of recovered oil, provided that:

(1) tank bulkheads are easily accessible for inspection;

(2) the continuous butt welding is to be used for the bulkhead plating, except that full penetration welding is used for the fillet weld at the connection of the bulkhead to the deck;

(3) other machinery spaces or pipe tunnels are to be fitted with mechanical ventilation giving at least 20 air changes per hour (calculated based on the tank capacity) and alarms for ventilation failure. The number of air changes required above is to be maintained in case of failure of any ventilation fan. Ventilation fans are to be of non-sparking type. The electric motor fitted in the ventilation duct is to be of certified safe type;

(4) tanks are to be subject to hydraulic testing at special surveys;

(5) the common boundary of tanks is to be subject to thickness measurement at special surveys if necessary.

3.2.2.7 All openings (sounding pipes, hatches for the deployment of portable recovered oil pumps and hoses) to tanks for recovered oil are to be located on open deck to prevent accumulation of oil vapour.

3.2.2.8 Tanks for recovered oil are to have suitable access from open deck for cleaning and gas-freeing, or small dedicated hatches for cleaning.

3.2.2.9 Tanks for recovered oil are in general to be provided with wash bulkheads in one of the following cases:

(1) 0.5*B* (*B* being breadth of the ship) is exceeded; or

(2) 0.1*L* (*L* being length of the ship) or 10 m is exceeded, whichever is the greater.

3.2.3 Access and other openings

3.2.3.1 Ventilation openings to safe spaces such as accommodation, service and machinery spaces, control stations and navigation bridge are not to be located inside gas-hazardous zones.

3.2.3.2 In general, no access door or any opening other than access openings and ventilation openings is to be permitted between safe spaces (such as accommodation, service and machinery spaces, control stations and navigation bridge) and gas-hazardous zones.

(1) Access doors may be accepted between such safe spaces and gas-hazardous zones of Category 1, provided that the following conditions are met:

① an air lock is to consist of two steel doors substantially gastight which are to be spaced not less than 1.5 m apart (watertight doors may be considered as gastight doors);

② safe spaces are under positive pressure mechanical ventilation in relation to the gas-hazardous zones;

③ the doors are to be self-closing and without any holding back arrangements;

④ signs are provided to warn that the doors are to be kept closed during oil recovery operations or cleaning and gas-freeing operations of recovered oil tanks.

(2) Any opening other than access openings and ventilation openings may be accepted between such safe spaces and gas-hazardous zones of Category 1, provided that the following conditions are met:

① the closing appliance is to be confirmed as gastight;

② signs are provided to warn that they are to be kept closed during oil recovery operations or cleaning and gas-freeing operations of recovered oil tanks, and means are provided to prevent unauthorized opening.

3.2.3.3 Where the access doors mentioned in 3.2.3.2 above are not used as the means of escape specified in statutory requirements and they will not be used (opened) during oil recovery operations or cleaning and gas-freeing operations of recovered oil tanks (including accidental and emergency conditions the ship might encounter during the operations), air locks may not be fitted. In addition to complying with the requirement that the doors are to be self-closing and without any holding back arrangements, the following requirements are at least to be met:

(1) gastight closing can be achieved, which has been confirmed;

(2) signs are provided to warn that the doors are to be kept closed during oil recovery operations or cleaning and gas-freeing operations of recovered oil tanks, and means are provided to prevent unauthorized opening.

3.2.3.4 Oil handling spaces on deck are to be provided with a coaming around all recovered oil pumps, transfer flanges and other connections. Each coaming is to have a height sufficient to prevent recovered oil from entering accommodation, machinery, control and service spaces or passing overboard. The coaming is to have a height of at least 150 mm. Where drains are provided for the coaming, closing devices for these drains are to be permanently attached.

3.2.4 Fire protection and extinction

3.2.4.1 For vessels with tanks for recovered oil forward of superstructures, exterior boundaries of superstructures and deckhouses enclosing accommodation, including any overhanging decks which support such accommodation, are to be insulated to A-60 class standard for all parts which face deck areas where there are arrangements for collection, handling and transfer of recovered oil as well as exterior surfaces within 3 m from the ends of boundaries facing these areas. The requirement is also applicable for access doors in such boundaries.

3.2.4.2 For vessels with tanks aft of superstructures, exterior boundaries of superstructures and deckhouses enclosing accommodation, situated within 10 m of the nearest tank for recovered oil, including any overhanging decks which support such accommodation, are to be insulated to A-60 class standard for all parts which face deck areas where there are arrangements for collection, handling and transfer of recovered oil as well as exterior surfaces within 3 m from the ends of boundaries facing these areas.

3.2.4.3 Portholes or windows in the exterior boundaries which are required to be insulated to A-60 class standard, as referred to in 3.2.4.1 of this Section, are to be of fixed (non-opening) type and are to be insulated to A-60 class standard, except for those in the navigation bridge.

3.2.4.4 As an alternative to compliance with 3.2.4.1 and 3.2.4.2, a fixed water spraying system may be used to protect all boundaries, portholes or windows which may, in this case, be insulated to A-0 class standard. The system is to be capable of delivering water at a rate of 10 *l*/min per m^2 at least and is to be readily available.

3.2.4.5 Working deck areas used for oil recovery operations, where there are arrangements for the collection, handling and transfer of recovered oil, are to be provided with the following fire-extinguishing equipment:

(1) two dry powder fire-extinguishers, each at least 50 kg capacity. The fire-extinguishers are to be located near the working deck and are to be fitted with discharge hoses having a length sufficient to reach the arrangements for the collection, handling and transfer of recovered oil;

(2) a large fire-extinguishing foam installation fitted with at least one portable foam applicator. The foam installation is to be so arranged that it is capable of applying foam to any part of the working deck. The capacity of any applicator is to be not less than 400 *l* /min of foam solution and the applicator throw in still air conditions is to be not less than 15 m. Sufficient foam concentrate is to be provided for at least 0.4 *l* /m^2 of the working deck area with a minimum quantity of 200 *l*. The foam expansion ratio is generally not to exceed 12 to 1.

3.2.4.6 Each recovery oil pump-room is to be provided with a fixed fire-extinguishing system suitable for machinery spaces of category A. The system controls are to be operated from a readily accessible position outside the pump-room. Where a carbon dioxide system is used, the quantity of carbon dioxide is to be sufficient to give a minimum volume of free gas equal to 45% of the gross volume of the tanks for recovered oil. A notice is to be exhibited at the controls stating that, due to the electrostatic ignition hazard, the system is to be used only for fire extinguishing and not for inerting purposes.

3.2.4.7 Oil recovery ships are to carry at least four fire-fighter's outfits.

3.2.5 Mechanical ventilation

3.2.5.1 The design, type and structure of mechanical ventilation systems may be dealt with in accordance with the relevant requirements for oil tankers.

3.2.5.2 Spaces with access to hazardous zones of Category 1 are to be kept under positive pressure mechanical ventilation during oil recovery operations, with the air intake located inside a safe area.
3.2.5.3 Spaces in hazardous zones of Categories 0 and 1 that are not frequently used during oil recovery operations are not to be ventilated, provided that the equipment therein is provided with the required explosion protection. For safety reasons, spaces in hazardous zones of Categories 0 and 1 that must be accessible at all times are to be equipped with a ventilation system of the extraction type, ensuring at least 8 air changes per hour.
3.2.5.4 Hazardous zones of Category 1 as specified in 3.1.4.1(2)⑤, ⑥ of Section 1 of this Chapter may be accepted as safe areas, provided that the following special ventilation requirements are complied with and positive pressure mechanical ventilation is maintained:
(1) the ventilation airflow is to be at least 20 air changes per hour;
(2) the arrangement of ventilation inlet and outlet openings in a space is to be such that the entire space is efficiently ventilated, taking special consideration to locations where gas may be released or may accumulate;
(3) the air intake is to be located in a safe area.
3.2.5.5 For the spaces required to be under positive pressure ventilation, audible and visual alarms are to be initiated at the navigation bridge or other suitable positions in case of loss of positive pressure ventilation.

3.2.6 Gas detection and alarm system

3.2.6.1 For the purpose of explosion protection, the ship is to be equipped with a permanently installed gas detection system, which will actuate an audible and visual alarm at the navigation bridge, open deck or other suitable positions when a concentration of hydrocarbon gas or similar products equal to 30% of the lower explosion limit (LEL) is exceeded.
Detection points may be arranged according to specific circumstances, generally close to ventilation air intakes, in air locks and on the main deck (at least one at the fore end and one at the aft end of the ship).
3.2.6.2 In addition to the above gas detection system, at least one portable instrument is to be available on board for gas detection.

Section 3 MACHINERY INSTALLATIONS

3.3.1 General requirements

3.3.1.1 All machinery equipment used in gas-hazardous zones during oil recovery operations is to be suitable for operation in gas contaminated atmosphere.
3.3.1.2 The exhaust lines of diesel engines, the flue ducts of boilers and the vents of diesel engine crankcases are to be led to a position outside the gas-hazardous zones as described in 3.1.4 of Section 1.
3.3.1.3 The exhaust lines of diesel engines and the flue ducts of boilers are to be provided with effective spark arresters.

3.3.2 Transfer system for recovered oil

3.3.2.1 A fixed transfer system for recovered oil is to be provided. The transfer system is to be arranged such that simultaneous filling and discharge will be possible. Unless provided otherwise, the transfer system for recovered oil is to be independent of all other piping systems onboard.
3.3.2.2 For coupling of portable skimming equipment, one or maximum two filling connections with branch pipes to all recovered oil tanks are to be arranged on deck.
3.3.2.3 Where recovered oil transfer pumps are driven by shafting which passes through a pump room bulkhead or deck, gastight glands are to be fitted to the shaft at the pump room plating. The glands are to be capable of being lubricated from outside the pump room and are to be so designed as to prevent overheating. The seal parts of the glands are to be of materials that will not initiate sparks. Where a bellows piece is incorporated in the design, it is to be hydraulically tested to 0.34 MPa before being fitted.
3.3.2.4 All recovered oil transfer pumps which are capable of developing a pressure exceeding the design pressure of the system are to be provided with relief valves. Each relief valve is to be so arranged as to discharge back to the suction side of the pump, and to effectively limit the pump discharge pressure to the design pressure of the system.
3.3.2.5 One pressure gauge for each recovered oil transfer pump is to be located at the pump discharge and, where the pumps are capable of being operated from outside the pump room, an additional gauge is to be provided which is to be visible from the operating station.

3.3.2.6 Piping systems related to oil recovered are to be arranged as follows:
(1) piping systems related to oil recovered are not to pass through machinery and accommodation spaces;
(2) piping systems related to oil recovered are not to pass through drinking water tanks, boiler water tanks or other tanks. Where it is unavoidable for piping systems to pass through other tanks, the portions of pipelines within tanks are to be all-welded extra thick pipes without valves, flanges, fittings or slip joints (see for wall thickness requirements in Table 5.3.4.2 of Chapter 5, PART THREE of the Rules).

3.3.3 Venting arrangements of tanks for recovered oil

3.3.3.1 Every tank for recovered oil is to be fitted with a vent pipe or other equivalent venting arrangement. The vent pipes are to be sized for 125% of the maximum loading rate to prevent the pressure in any recovered oil tank from exceeding the design pressure; however, the diameter of each vent pipe is to be not less than 60 mm. Venting outlets are to be led to open deck. Gas from the outlets is to be discharged directly upwards.
3.3.3.2 The outlets are to have a minimum height of 2.4 m above deck and be located at a minimum horizontal distance of 5 m away from openings to accommodation and other gas-safe spaces, ventilation intakes for accommodation and machinery spaces and non-certified safe electrical equipment.
3.3.3.3 The end of vent pipes is to be fitted with a corrosion resistant flameproof wire gauze capable of being easily renewed.
3.3.3.4 Vent pipes are also to comply with the applicable requirements of Chapter 3, PART THREE of the Rules.
3.3.3.5 For multi-purpose oil recovery ships, portable vent pipes intended for use during oil recovery operations only, may be accepted.

3.3.4 Other systems related to recovered oil

3.3.4.1 Tanks for recovered oil are to be fitted with suitable means for determining the level within the tanks. Sounding pipes, if fitted for this purpose, are to terminate in the open air above freeboard deck. The internal diameter of sounding pipes is not to be less than 50 mm.
3.3.4.2 Provisions are to be made to guard against liquid rising in recovered oil tanks to a height which would exceed the design head of the tanks. This may be accomplished by high-level alarms or overflow control systems or other equivalent means, together with independent gauging devices and tank filling procedures. The high level alarm is to be capable of giving an audible and visual alarm at the recovered oil control station.
3.3.4.3 The heating systems and other steam pipelines fitted to recovered oil tanks are to comply with the relevant requirements of Chapter 5, PART THREE of the Rules.
3.3.4.4 Bilge drainage of the recovered oil transfer pump room and the cofferdam within the gas-hazardous zones is to be effected by powered pumps or bilge ejector suctions independent of the bilge drainage system of safe spaces. The pump room bilge is to be drained into the tanks for recovered oil.
For oil recovery ships of not more than 500 gross tons, the pump room bilge may be drained by a hand pump having at least a 50 mm bore suction.
3.3.4.5 The ballast piping system serving gas-hazardous zones is to be independent of that serving safe spaces. The ballast pump is to be located in the recovered oil pump room or other suitable gas-hazardous space.

3.3.5 Machinery equipment and systems in gas-hazardous zones

3.3.5.1 The oil recovery equipment and hoses are to be electrically bonded into the ship's hull. The cross-sectional area of the metallic bonding strap is to be not less than 10 mm^2.
3.3.5.2 Hoses are to be electrically well conductive.
3.3.5.3 No sparks are allowed during operation of the oil recovery equipment.
3.3.5.4 Surface temperature of the equipment is not to exceed 200℃.

Section 4 ELECTRICAL INSTALLATIONS

3.4.1 General requirements

3.4.1.1 Unless specified otherwise in this Section, electrical equipment, cables and distribution systems are to comply with the relevant requirements of Section 16, Chapter 2 of PART FOUR of the Rules.
3.4.1.2 The equipment used for oil recovery operation and deck areas used for storing hoses are to have adequate lighting.

3.4.1.3 The power distribution systems of oil recovery ships having the notation Oil Recovery Ship without Cargo Tank are to comply with Section 4, Chapter 2 of PART FOUR of the Rules.

3.4.2 Electrical equipment in gas-hazardous zones

3.4.2.1 The use of electrical appliances in gas-hazardous zones as specified in 3.1.4 of Section 1 is to be restricted to operationally essential equipment and is to comply with Table 3.4.2.1.

Electrical Equipment Permitted in Gas-Hazardous Zones Table 3.4.2.1

Category of hazardous zones	Type of electrical equipment	Cable
0	Intrinsically safe Ex" ia"	Cables associated with intrinsically safe equipment in such zones
1	Intrinsically safe Ex" ia", Ex" ib"	Cables associated with the equipment in such zones; through runs of cables
	Flameproof Ex" d"	
	Increased safety Ex" e"	
	Pressurized enclosure Ex" p"	
	Powder filled Ex" q"	
	Encapsulated Ex" m"	

3.4.2.2 The explosion-proof electrical equipment listed in Table 3.4.2.1 is to meet at least the following requirements:

Temperature class T3;

Equipment group II A.

3.4.2.3 All equipment not complying with 3.4.2.1 of this Section and located in the gas-hazardous zones as specified in 3.1.4 of Section 1 are to be disconnected during oil recovery operation. The switches for such disconnection are to be safeguarded against unintentional re-connection and appropriately marked to that effect.

3.4.2.4 The flexible cables without armor or metal braid may be applied in zones of Category 1, provided that the construction and installation of such cables are to comply with acceptable standards①, as appropriate.

3.4.2.5 Portable oil recovery equipment and recovered oil pumps are to comply with the following requirements:

(1) Portable oil recovery equipment and recovered oil pumps are to be supplied from a permanently installed distribution box or socket outlet.

(2) Socket outlets for power circuits are to be interlocked in such a way that the plug can be neither inserted nor withdrawn when the socket contacts are live.

(3) The socket outlet as the separate final sub-circuit is to be provided with a circuit breaker capable of overcurrent and short-circuit protection in each insulated phase. The supply to the socket-outlet is to be permanently installed.

(4) Socket outlets are to be located at easily accessible places and in such a way that flexible cables are not carried through doors or portlights leading from working deck to machinery or accommodation spaces.

Section 5 OPERATING MANUAL

3.5.1 Operating manual

3.5.1.1 The ship is to be provided with an approved operating manual. In general, the operating manual is to contain a description of the safety precautions needed when preparing for and carrying out oil recovery operations.

3.5.1.2 The operating manual for oil recovery ships is to include:

(1) Equipment and arrangement

① arrangement of recovered oil tanks;

② transfer system for recovered oil;

③ gas-measuring instrument;

④ other associated units of equipment.

(2) Preparations for operation

---

① Refer to IEC publication 60079-14: Explosive atmospheres – Part 14: Electrical installations design, selection and erection.

① checking all equipment on board to determine compliance with 3.3.1.1 of Section 3 and 3.4.2.1 of Section 4;
② mounting and fastening of non-permanent equipment;
③ blanking off particular pipes;
④ assembling air pipes;
⑤ disconnecting power supply to those electrical installations not complying with 3.4.2.1 of Section 4;
⑥ closing openings between safe areas and gas-hazardous zones;
⑦ starting up additional ventilation equipment;
⑧ changeover to low suction for cooling water pumps;
⑨ displaying signs to the effect that open flame, non-certified explosion-proof electrical equipment, etc. are prohibited.

(3) Oil recovery operation
① guidance on safe distance from an oil spill source and relevant notes;
② gas measurements during operation (on open deck and in spaces where gas may accumulate). If gas is traced on open deck, the ship is to move away immediately;
③ actions to be taken for cleaning, ventilation, emptying adjacent tanks, etc., if gas is traced in any enclosed space;
④ emergency measures to be taken in case of failure of positive pressure ventilation;
⑤ precautions against overfilling of recovered oil tanks;
⑥ discharging.

(4) Cleaning and gas-freeing of recovered oil tanks and pipes.

Section 6 OIL RECOVERY SHIPS CARRYING RECOVERED OIL HAVING A FLASH POINT EXCEEDING 60℃

3.6.1 General requirements

3.6.1.1 Ships engaged exclusively in the recovery of oil having a flash point exceeding 60℃ are to comply with the relevant requirements of Sections 1 (excluding paragraph 3.1.4) and 5 of this Chapter, and the following additional requirements.

3.6.2 Construction and fire safety

3.6.2.1 Ships engaged exclusively in the recovery of oil having a flash point exceeding 60℃ are to comply with the requirements of Chapter 2, PART TWO of the Rules.

3.6.2.2 The fire safety of ships engaged exclusively in the recovery of oil having a flash point exceeding 60℃ are to comply with the relevant requirements for cargo ships and the following additional requirements:

(1) In working deck areas, fire-extinguishing equipment required in 3.2.4.5 of this Chapter is to be provided in lieu of the fixed fire-extinguishing system required for cargo spaces of cargo ships.

(2) All openings of tanks for recovered oil are to be located in accordance with the requirements of 3.2.2.7 of this Chapter.

(3) Spill coamings and drains are to be provided in accordance with the requirements of 3.2.3.4 of this Chapter.

(4) Fire-fighter's outfits are to be provided in accordance with the requirements of 3.2.4.7 of this Chapter.

(5) At least one portable instrument is to be available on board for gas detection.

3.6.3 Machinery installations

3.6.3.1 For ships engaged exclusively in the recovery of oil having a flash point exceeding 60℃, paragraphs 3.3.2.1, 3.3.2.2, 3.3.2.4, 3.3.2.5, 3.3.2.6, 3.3.4.1, 3.3.4.2 and 3.3.4.3 of this Chapter are applicable. However, subparagraph 3.3.2.6(1) may be replaced by the following:

(1) piping systems related to oil recovered are not to pass through machinery and accommodation spaces as far as practicable; where this is unavoidable, the arrangement of such piping systems within machinery spaces is to comply with the requirements for fuel oil piping systems.

3.6.3.2 The venting arrangements of tanks for recovered oil are to comply with the requirements of 3.3.3 of this Chapter, or the requirements for fuel oil tanks in Chapter 3, PART THREE of the Rules.

3.6.4 Electrical installations

3.6.4.1 The additional requirements for electrical installations of ships engaged exclusively in the recovery of oil having a flash point exceeding 60℃ are to be in compliance with 2.16.7 of Section 16, Chapter 2, PART FOUR of the Rules.

CHAPTER 4 SHIP BRIDGE DESIGN AND EQUIPMENT

Section 1 GENERAL PROVISIONS

4.1.1 General requirements

4.1.1.1 This Chapter applies to ships applying for the notations as specified in 4.1.2 of this Chapter..

4.1.1.2 The provisions of this Chapter are not to prevent the ship from complying with the relevant IMO conventions, codes and requirements of the Administration of the Flag State.

4.1.2 Notations

4.1.2.1 Ships of which bridge design and equipment installed complying with the following provisions may be assigned with the following notations upon application:

(1) BDE-1 is applicable to ships complying with the basic design requirements, working environment and the required equipment to be installed in Sections 1 to 5 of this Chapter;

(2) BDE-2 is applicable to ships complying with the requirements in Sections 1 to 6 of this Chapter;

(3) BDE-3 is applicable to ships of which the bridge is fitted with the Integrated Bridge System (IBS) complying with requirements in Sections 1 to 7 of this Chapter.

4.1.3 Definitions

4.1.3.1 For the purpose of this Chapter:

(1) Workstation means position at which one, or several tasks constituting a particular activity are carried out.

(2) Navigator means person navigating, operating bridge equipment and manoeuvring the ship.

(3) Back-up navigator means any individual, generally an officer, who has been designated by the ship's master to be on call if assistance is needed on the navigation bridge.

(4) Officer of the watch means person responsible for operating of bridge equipment and manoeuvring of the ship.

(5) Bridge means that area from which the navigation and control of the ship is exercised, including the wheelhouse and bridge wings.

(6) Wheelhouse means enclosed area of the bridge.

(7) Bridge wings are those parts of the bridge on both sides of the ship's wheelhouse which, in general, extend to the ship's side.

(8) Field of vision means angular size of a scene that can be observed from a position on the ship's bridge.

(9) Lookout means activity carried out by sight and hearing as well as by all available means appropriate in the prevailing circumstances and conditions so as to make a full appraisal of the situation and of the risk of collision.

(10) Watch alarm means alarm that is transferred from the bridge to the master and the back-up navigator in case of any officer of the watch deficiency (absence, lack of alertness, no response to another alarm/warning, etc.).

(11) Workstation for navigation manoeuvring means a workstation with a commanding field of vision used by a navigator during course monitoring, traffic monitoring, course change and speed change, which can monitor the ship's safety condition.

(12) Workstation for monitoring means a workstation that facilitates the operation of equipment and observation of the ship's heading, speed, water and traffic with a commanding field of vision, including means necessary for route monitoring, to be used by the officer of the watch, backup navigator or pilot as needed for effective bridge team operation. The station may be considered as part of the workstation for navigation manoeuvring when paper charts or ECDIS are used for route monitoring.

(13) Workstation for manual steering means a workplace where the helmsman manually controls the ship's required ield of vision, indicators and equipment according to the instructions given by the navigator in charge of bridge operation.

(14) Workstation for docking means a workplace on the bridge wing that provides the field of vision and information required to control ship manoeuvring, tug operation and mooring operation along the berth.

(15) Workstation for plan development means a workplace used to plan the route of the entire voyage from place of departure to place of destination and to record the bridge operations during the voyage.

(16) Workstation for safe operation means a workplace dedicated to the organization and control of onboard emergency and distress operations with easy access to external and internal communications and information relevant to the safe status of the ship.

(17) Workstation for communication means a workplace for the operation and control of Global Maritime Distress and Safety System (GMDSS) equipment and on-board communications for ship operation under normal and emergency conditions.
(18) Commanding field of vision means the field of view within which there is no obstacle to the ability of the on-duty navigator and pilot to perform their main tasks, and it is at least to provide the field of vision required by the safe performance of collision avoidance function. It is required that the sea field of vision from the front of the bow to 10° of either side of the ship is not to be obscured by more than two ship's lengths or 500 m, whichever is less, and that the horizontal view extends to a sector of at least 225°, that is, from dead ahead to either side of the ship is not less than 22.5° abaft the beam.
(19) Command position means a position located in the bridge, to monitor and guide the ship through the narrow water and buoy channel by visual observation, and provide the commanding field of vision, close field of vision of the sea surface and the information needed for maneuvering.
(20) Ship length means the length as defined in Reg.3.10, Chapter 1 of the International Regulation for Prevention Collision at Sea, 1972 , i.e. overall length of the ship.

4.1.4 Plans and documents

4.1.4.1 The following plans and documents are to be submitted for approval:
(1) Bridge visibility calculations, including scantlings of bridge, inclination and dimensions of windows and dimensions of consoles and so on;
(2) Arrangement of bridge, including positions of workstations, navigational equipment and consoles etc.;
(3) Arrangement of console panels;
(4) Diagram of power supply system for navigational equipment, internal communication equipment etc.;
(5) layout and power supply of cameras, where applicable.

Section 2 BRIDGE LAYOUT

4.2.1 General requirements

4.2.1.1 The bridge configuration, the arrangement of consoles and equipment locations is to enable the officer of the watch to perform navigational duties and other functions allocated to the bridge as well as maintain a proper lookout from a convenient position on the bridge.
4.2.1.2 A workstation for navigation manoeuvring is to be arranged to enable efficient operation by one person under normal operating conditions. All relevant instrumentation and controls are to be easily visible, audible and accessible from related workstations.
4.2.1.3 The bridge layout and design of workstations are to enable the ship to be navigated and manoeuvred safely by two navigators in cooperation.
4.2.1.4 External sound signals and fog signals from outside the ship that are audible on the open deck, are also to be audible inside the wheelhouse; a transmitting device is to be provided to reproduce such signals inside the wheelhouse (recommended frequency range: 70 Hz to 700 Hz).
4.2.1.5 A workstation for navigation manoeuvring is to be arranged on the starboard side near the center line, where applicable..
4.2.1.6 A workstation for monitoring is to be arranged on the port side near the center line, where applicable.
4.2.1.7 A Workstation for manual steering is to generally be located at the center line of the ship.
4.2.1.8 Sufficient manoeuvring positions are to be provided near the middle front window. If the view in the center line is obstructed by large masts, cranes, etc., two manoeuvring positions with a clear forward view are to be provided, one at the left side of the center line and the other at the right side, spaced not more than 5 m.

4.2.2 Field of vision

4.2.2.1 In order to obtain sufficient field of vision for safe navigation and manoeuvring of the ship, every effort is to be made to place the bridge above all other decked superstructures.
4.2.2.2 The view of the sea surface from the workstations for navigation manoeuvring is not to be obscured by more than two ship's lengths or 500 m, whichever is less, forward of the bow to 10º on either side, irrespective of the ship's draught, trim and deck cargo, as shown in Figure 4.2.2.2.

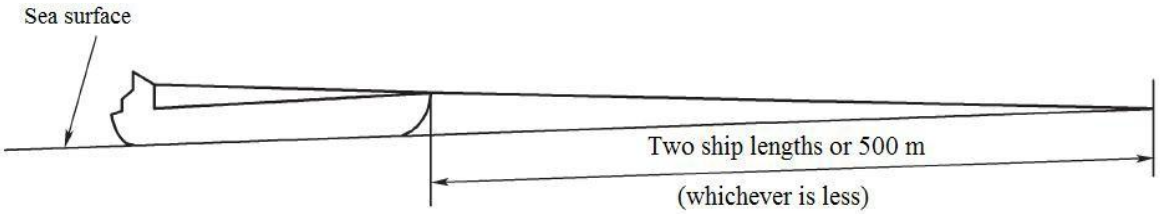

Figure 4.2.2.2 Forward View

4.2.2.3 No blind sector caused by cargo, cargo gear or other obstructions outside of the wheelhouse forward of the beam which obstructs the view of the sea surface as seen from the workstations for navigation manoeuvring is not to exceed 10º. The total arc of blind sectors is not to exceed 20º. The clear sectors between blind sectors are to be at least 5º. However, in the view described in 4.2.2.2, each individual blind sector is not to exceed 5º.

4.2.2.4 The horizontal field of vision from the workstations for navigation manoeuvring is to extend at least over an arc from 22.5º abaft the beam on one side, through forward, to 22.5º abaft the beam on the other side, as shown in Figure 4.2.2.4.

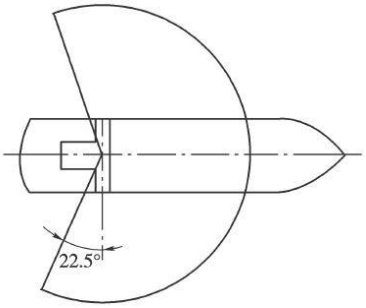

Figure 4.2.2.4 Field of Vision from the Workstations for Navigation Manoeuvring

4.2.2.5 The horizontal field of vision from the workstation for manual steering is to extend over an arc from right ahead to at least 60º on each side of the ship, as shown in Figure 4.2.2.5.

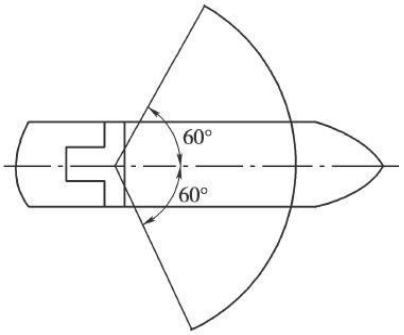

Figure 4.2.2.5 Horizontal Field of Vision from the Workstation for Manual Steering

4.2.2.6 The horizontal field of vision from workstation for docking is to extend over an arc from 45º on the opposite bow through dead ahead and then aft to 180º from dead ahead, as shown in Figure 4.2.2.6.

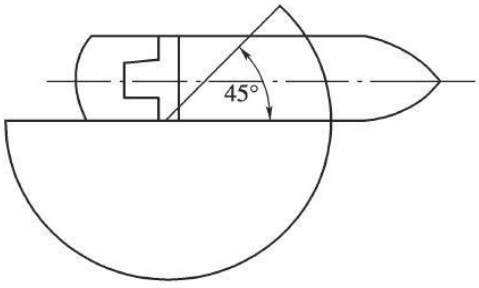

Figure 4.2.2.6 Horizontal Field of Vision From the Workstation for Docking

4.2.2.7 At a workstation for monitoring, the field of vision is to enable the officer of the watch to maintain a proper lookout. The field of vision is to extend at least over an arc from 90º on port bow, through forward, to 22.5º abaft the beam on starboard, as shown in Figure 4.2.2.7.

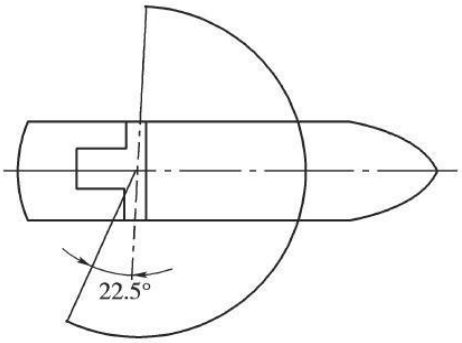

Figure 4.2.2.7 Field of Vision form Workstations for Monitoring

4.2.2.8 The ship's side is to be visible from the bridge wing.①

4.2.3 Windows

4.2.3.1 All windows in the wheelhouse are to be of shatter-proof reinforced glass, the thickness of which is to comply with acceptable standards②. Polarized and stained glass windows are not to be installed.

4.2.3.2 Windows are to be as wide as possible. Framing between windows is to be kept to a minimum and not installed immediately forward of any workstation.

4.2.3.3 To help avoid reflections, the bridge front windows are to be inclined as possible from the vertical plane top out, at an angle of not less than 10º and not more than 25º. Alternative means are to be approved by ISC.

4.2.3.4 The height of the lower edge of front windows is to allow a forward view above the bow from the workstation for navigation manoeuvring. To achieve this, the height of the lower edge above the deck is not to exceed 1 m as practicable.

4.2.3.5 The upper edge of the navigation bridge front windows are to allow a forward view of the horizon, for a person with a height of eye of 1.8 m above the bridge deck at the conning position, when the ship is pitching in heavy seas. If deemed that a height of eye of 1.8 m is unreasonable and impractical, reduction of the height of eye may be allowed, but not to less than 1.6 m.

4.2.3.6 At all times, regardless of weather conditions, at least two windows in front of the workstations for navigation manoeuvring, monitoring and docking (if practical) are to provide a clear view.

4.2.3.7 To ensure a clear view in bright sunshine, sunscreens of roller blind type with minimum colour distortion are to be affixed to windows that are within the required field of vision from the workstations. Such screens are to be readily removable and not to be permanently fixed.

4.2.3.8 At least two windows in front of the workstations for navigation manoeuvring, monitoring and docking (where applicable) are to be provided with efficient cleaning, de-icing and de-misting systems to ensure a clear view under all operating conditions.

4.2.3.9 A safe external passageway or similar arrangement is to be provided under the bridge front window to enable cleaning in the event of failure of the systems specified in 4.2.3.8 of this Section.

4.2.4 Layout and dimensions

4.2.4.1 The design of the net height of the wheelhouse ceiling is to take into account the overhead mounted panels and equipment. There is to be at least 2.25 m between the wheelhouse deck and the ceiling beams. The lower edge of ceiling mounted equipment is to be at least 2.1 m above the deck of open areas, walkways and standing-type workstations.

4.2.4.2 Workstations are to be divided into two areas as far as possible:

(1) the vertical (tilted) part so that the display is in a position that is easy to read;

(2) the horizontal part (table top) so that the controller, switch and button are within easy reach of the working position.

---

① Refer to IMO MSC.1/Circ.1350/Rev.1.

② Refer to ISO 21005 Ships and marine technology − Thermally toughened safety glass panes for windows and sidescuttles.

4.2.4.3 The height of the console desktop of the workstation for navigation manoeuvring and the workstation for monitoring is to make it easy to use the equipment required for safe execution of the tasks performed from the standing and sitting positions.
4.2.4.4 The chart table is to be large enough to accommodate all nautical chart sizes in common use internationally, and appropriate lighting is to be provided.
4.2.4.5 Instruments and equipment operated by the navigator at the workstation for navigation manoeuvring are to be within reach of the manoeuvring.
4.2.4.6 Instruments, indicators and displays providing information considered essential for the safe and efficient performance of tasks at the workstation for navigation manoeuvring are to be easily readable from this workstation.

4.2.5 Passageways

4.2.5.1 A passageway through the wheelhouse from bridge wing to bridge wing is to be provided. The width of the passageway is to be at least 1200 mm, but if there are obstacles on the route of the passageway, the width of the passageway at the obstacle can be reduced to 700 mm without affecting the staggered passage of two wheelhouse personnel.
4.2.5.2 The distance between adjacent workstations is to be sufficient to allow the unimpeded passage of persons not working at the station. The passage space of the corridor between different workstation areas is to be at least 700 mm. The workstation operation area is to be a part of the workstation, not a passageway.

4.2.6 Doors

4.2.6.1 Doors to the bridge are to be capable of being secured from inside and manually operated. Doors to the bridge wings are not to be self-closing and means are to be made to keep them open.

Section 3 WORKING ENVIRONMENT

4.3.1 Lighting

4.3.1.1 An adequate level of lighting facilitating the performance of all bridge tasks at daytime and nighttime is to be provided. With illumination inside the equipment or the lighting system in the wheelhouse, controls, indicators, instruments, keyboard etc. are to be clearly visible.
4.3.1.2 All lighting of instruments, keyboards and controls are to be adjustable down to zero, except the lighting of alarm indicators and the control of dimmers, which are to remain readable.
4.3.1.3 The lighting on the bridge is to be supplied by two exclusive circuits, with one of which fed from an emergency source of electrical power, in such a way that failure of any one of the circuits does not leave the bridge in darkness.
4.3.1.4 The lighting on the bridge is to be designed so as not to impair the night vision of the officer on watch. Lighting used in areas and at items of equipment requiring illumination whilst the ship is navigating is to be such that night vision adaptation is not impaired, e.g. red lighting. Such lighting is to be arranged so that it cannot be mistaken for a navigation light by another ship. It is to be noted that red lighting is not to be fitted over the chart table so that possible confusion in colour discrimination is avoided.
4.3.1.5 High contrast between the brightness of the working area and the surrounding environment is to be avoided, that is, the brightness of the working area is not to be greater than 3 times the average brightness of the surrounding area.
4.3.1.6 Lighting sources are to be designed and positioned to avoid glare on working and display surfaces. The light sources are not to produce a detectable flicker.

4.3.2 Personnel safety precautions

4.3.2.1 The bridge area is to be free of physical hazards to bridge personnel. There are to be no sharp edges or protuberances which could cause injury to personnel. The wheelhouse, bridge wings and bridge deck are to be free of trip hazards and to have a non-slip surface whether it is wet or dry.
4.3.2.2 Sufficient hand-rails or equivalent thereto are to be fitted in the wheelhouse and around workstations to enable personnel to move or stand safely in bad weather. Special consideration is to be given to the protection of stairway openings.
4.3.2.3 For seating in the wheelhouse, means for securing are to be provided.
4.3.2.4 All safety equipment on the bridge is to be clearly identified and easily accessible and its storage location is to be clearly indicated.

4.3.3 Temperature and humidity

4.3.3.1 According to climate, adequate air-conditioning or mechanical ventilation system and efficient heating system are to be provided to maintain the temperature in the wheelhouse within the range of 14℃~ 30℃. The controls of these systems are to be fitted in the wheelhouse.
4.3.3.2 Air flow from air conditioning and heating systems to the workplace is to be avoided.

4.3.4 Noise
4.3.4.1 The noise level on the bridge is not to interfere with verbal communication, mask audible alarms or be uncomfortable to bridge personnel. The noise level in the wheelhouse is not to exceed 65 dB(A) in good weather. However, the noise level in the communication workstation) is not to exceed 60dB(A).

4.3.5 Vibration
4.3.5.1 The vibration level on the bridge is not to be uncomfortable to the bridge personnel.

4.3.6 Glare-free
4.3.6.1 A glare-free coating is to be applied on the front surface of bulkheads, deckhead, consoles, chart table and other essential equipment. Means are to be provided to prevent dimming of the information shown by visual displays and instruments covered by transparent sheeting.

Section 4 WORKSTATIONS

4.4.1 General requirements
4.4.1.1 According to its functions, the ship bridge can be divided into workstation for navigation manoeuvring, workstation for monitoring, workstation for manual steering, workstation for planning development, workstation for communication, workstation for docking and workstation for safe operation.
4.4.1.2 The workstation for navigation manoeuvring, workstation for monitoring and workstation for manual steering are functionally related and generally close to each other, so there is no need to re-equip these stations with relevant equipment.

4.4.2 Workstation for navigation manoeuvring
4.4.2.1 The workstation for navigation manoeuvring is generally to be provided with the following equipment:
(1) radar / ARPA;
(2) display of positioning system;
(3) depth indicator;
(4) speed and distance indicator;
(5) display of gyro compass system;
(6) wind direction and speed indicator;
(7) indicator of steering gear and rudder angle;
(8) rate-of-turn indicator;
(9) course and track monitoring system;
(10) controls and indicators for main and athwartship propulsion;
(11) verification device and manually activating device used for bridge navigation watch alarm system (BNWAS);
(12) an internal communication system (see 4.5.5);
(13) VHF radiotelephone installation;
(14) clock;
(15) window wipe and wash control device;
(16) navigation light control;
(17) whistle control device;
(18) Morse lamp key;
(19) lighting control of wheelhouse and equipment;
(20) display for the Automatic Identification System (AIS)；
(21) a device that stops sending Long-Range Identification and Tracking (LRIT) messages, if applicable;
(22) Electronic Chart Display and Information System (ECDIS);
(23) night vision equipment, if applicable.
4.4.2.2 The ship is to be provided with two separate and independent radar systems. At least one of the radars is to operate within the X-band. The radars are to be capable of detecting and clearly indicating any

input signal loss (e.g. video or azimuth signal). The ship is also to be equipped with an ARPA system which may be independent or built into the radar equipment.
4.4.2.3 At least two positioning systems capable of continuously displaying latitude and longitude are to be fitted, one of which is to be electronic positioning system with global coverage and the other is to be electronic positioning system with differential correction function.
4.4.2.4 An off-course alarm independent of automatic steering system is to be provided. Where an automatic track-keeping system is provided, an off-course alarm may be initiated by the positioning system in case of deviation from the planned route to the set distance.
4.4.2.5 Where an automatic track-keeping system is provided, a pre-warning is to be given at the approach of a way-point so that the back-up navigator will have sufficient time to reach the wheelhouse for acknowledging course alteration in case of any officer of the watch deficiency. The course is not to be automatically altered without prior confirmation.

4.4.3 Workstation for monitoring

4.4.3.1 The workstation for monitoring is generally to be provided with the following equipment:
(1) radar /ARPA;
(2) the display of the depth sounder;
(3) speed and log display;
(4) compass display;
(5) steering gear and rudder angle indicator;
(6) rotation rate indicator;
(7) controllers and indicators for main propulsion and side push;
(8) BNWAS confirmation device and manual starting device;
(9) Internal communication system (see 4.5.5);
(10) VHF radio telephone;
(11) time indicator;
(12) window cleaning controller;
(13) air whistle controller.

4.4.4 Workstation for manual steering

4.4.4.1 The workstation for manual steering is generally to be provided with the following equipment:
(1) steering wheel/helmsman's handle;
(2) steering gear selection switch;
(3) compass display;
(4) steering gear and rudder angle indicator;
(5) rotation rate indicator.

4.4.5 Workstation for plan development

4.4.5.1 The workstation for plan development is to enable the following tasks to be performed:
(1) determining the ship’s position;
(2) planning the forthcoming voyage and estimating time of arrival at various way-points;
(3) indicating time.
4.4.5.2 The time indication at the workstation for plan development is to be derived from the same system as the workstation for navigation manoeuvring.

Section 5 EQUIPMENT AND SYSTEMS

4.5.1 Basic requirements for equipment

4.5.1.1 Navigation equipment is to be subject to type approval and the performance standards are not to be inferior to those of IMO in force.
4.5.1.2 All instruments and panels are to be permanently mounted in consoles or at other appropriate places, taking into account both operational and environmental conditions.
4.5.1.3 When siting equipment which is to be used in an exposed position, special care is to be taken to ensure that the siting does not impair the performance of the equipment.
4.5.1.4 Antenna and sensor arrangements which are part of navigational instruments, are to be widely separated from radio communications systems.
4.5.1.5 Antenna units are to be sited so as not to constitute a hazard to personnel working in the vicinity.

4.5.1.6 Satcom and radar antenna units are required to have a warning label, detailing safe distances, posted in the vicinity or on the equipment.
4.5.1.7 Above-deck equipment is to be sited so as to prevent the installation from being affected by vibration.
4.5.1.8 Instruments to be installed are to be located away from excessive heat sources, such as a heating vent or equipment heat exhaust.
4.5.1.9 Instruments to be fitted into a bridge instrument console are to be protected from excessive heat by conduction or, if necessary, by forced air flow.
4.5.1.10 Equipment not specifically designed for outdoor installation is not to be installed near a doorway, open window or hatch opening.
4.5.1.11 When equipment is being installed, care is to be taken to ensure that the accuracy of the ship's magnetic compasses is adequately safeguarded.

4.5.2 Computer-based systems and software
4.5.2.1 Computer-based systems are subject to type approval, and are to comply with the applicable requirements of Section 6, Chapter 2, PART SEVEN of the Rules.
4.5.2.2 Where failure in computer-based systems may affect safe navigation and manoeuvring of the ship, back-up systems are to be available for changeover.
4.5.2.3 Adequate filtering of analogue and digital input signals is to be provided.
4.5.2.4 Software and data necessary to ensure satisfactory performance of the computer system are to be stored in a non-volatile memory, or a volatile memory with an uninterruptible power supply.
4.5.2.5 Access to the computer's operating system is to be restricted, and any alteration of system software after final inspection and testing on board is to be subject to prior approval by ISC.
4.5.2.6 Necessary quality attributes for software are reliability, safeguard against error and misuse, fault detection and correction.
4.5.2.7 Where computerized equipment are interconnected through a computer network, failure of the network is not to prevent individual equipment from performing their individual functions.

4.5.3 Alarm system
4.5.3.1 Alarms released by navigation equipment are to be both audible and visual and to be displayed as group alarm for easy identification.
4.5.3.2 Alarms are to be set for the following as a minimum:
(1) the closest point of approach;
(2) insufficient depth of water;
(3) approach of a way-point;
(4) yaw;
(5) off-track;
(6) steering gear failure;
(7) navigation light failure;
(8) gyrocompass failure.

4.5.4 BNWS
4.5.4.1 The wheelhouse is to be provided with a BNWAS, the performance of which is to comply with the requirements of IMO resolution MSC.128(75).

4.5.5 Communication
4.5.5.1 A telephone system is to be provided for two-way speech communication between the bridge and at least the following (the telephone system is to function properly in case of loss of main power supply):
(1) engine control station;
(2) emergency steering position in steering gear room;
(3) cabins of captain and officers, offices, mess and public areas.
4.5.5.2 The bridge is to have priority over the communication system.
4.5.5.3 All extension numbers are to be shown at any telephone.

4.5.6 Power supply
4.5.6.1 Local distribution panels are to be arranged for all items of electrically operated navigational equipment etc. These panels are to be supplied by two exclusive circuits, one fed from the main source of electrical power and the other fed from an emergency source of electrical power. Each item of navigational equipment is to be individually connected to its distribution panel. The power supplies to the distribution

panels are to be arranged with automatic changeover facilities between the two sources. Failure of any power source is to initiate an audible and visual alarm.
4.5.6.2 Following a loss of power which has lasted for 45s or less, all primary functions are to be readily reinstated. Following a loss of power which has lasted for more than 45s, as many as practical primary functions are to be readily reinstated.

4.5.7 Man-machine interface

4.5.7.1 All instruments are to be logically grouped according to their functions within each workstation. Their location and design are to give consideration to the physical capabilities of the human operator and comply with accepted ergonomic principles.
4.5.7.2 The amount of information to be presented for conducting various tasks as well as the methods of displaying the information needed are to give consideration to the capabilities of the human operator to percept and process the information made available.
4.5.7.3 Instruments or displays providing visual information to more than one person are to be located for easy viewing by all users concurrently. If this is not possible, the instruments or displays are to be duplicated.
4.5.7.4 The method of presentation is to ensure that the instrument data is clearly visible to the observer at a practicable distance in the light conditions normally experienced on the bridge by day and by night.
4.5.7.5 Means are to be provided for the manual adjustment of the brightness of each visual display unit.
4.5.7.6 All information is to be presented on a background of high contrast, emitting as little light as possible by night.
4.5.7.7 Paged displays are to be presented in a way which allows the operator to find quickly the information needed. An overview page is to be easily available to remind the operator of the paging system.
4.5.7.8 Each page is to have a unique identifying label on the screen.
4.5.7.9 The function and layout of control elements are to be logically coordinated.
4.5.7.10 Maloperation of a computer-based bridge instrument is not to cause any loss of data, damage of programmes or malfunction of the system.
4.5.7.11 Default values, where applicable, are to be indicated by the system when requesting operator input.
4.5.7.12 If an input error is detected by the system, the operator is to be allowed to correct the error immediately.
4.5.7.13 The system is to require confirmation from the operator for critical actions, e.g. they are not to rely on single keystrokes.

Section 6 SUPPLEMENTARY REQUIREMENTS FOR THE NOTATION BDE-2

4.6.1 General requirements

4.6.1.1 Ships applying for the notation BDE-2 are to comply with the requirements of this Section in addition to the applicable requirements of other sections of this Chapter.

4.6.2 Field of vision

4.6.2.1 It is to be possible to observe all objects of interest for the navigation, such as other traffic and navigation marks, in any direction from inside the wheelhouse. Bearing this in mind, the observer is to obtain a 360º field of vision from inside the wheelhouse when moving within a certain range there. For rear view, other measures of the equivalent level of safety are acceptable, such as cameras with redundancy covering any obstructing view or blind area, if the 360 ° field of vision requirement around the ship cannot be met.
4.6.2.2 At the workstation for navigation manoeuvring, in the horizontal plane to vertical 5° above the line of sight, there is to be no obstruction; any structure/equipment or cargo obstructing the sea surface near the vessel in excess of 1000 m within a 180º sector in front of the lateral vessel in a line of sight from the horizontal plane to 5° below vertical is to be considered a blind area and the necessary calculations is to be carried out (eye height 1800 mm).
4.6.2.3 In all draft, trim and deck cargo conditions, the wheelhouse from the commanding position is to be able to observe all objects, shoreline and water at least 500 m from the hull within a sector of 10º to 90° on each side of the bow. If the vessel cannot meet the above requirements, measures of the equivalent level of safety are acceptable, such as cameras with redundancy covering any obstructing view or blind area.

4.6.2.4 In the process of ship manoeuvring, the navigator at the workstation for docking is to be able to observe the parallel ship side (eye height: 1600 mm). The total length of visibility on the ship's side is not to be less than 1/2 of the ship length.

4.6.3 Windows

4.6.3.1 To prevent reflection, the rear and side windows are to be tilted outwards at an angle of not less than 5° at the top of the vertical plane. The window in the bridge wing door may be exempted from this requirement.

4.6.4 Layout and dimensions

4.6.4.1 To provide accessibility from a standing position, the height of the console table top above the wheelhouse deck surface is to be not higher than 800 mm and not lower than 750 mm. For easy operation of the control device from the sitting position, it is to be possible to adjust the sitting height so that the elbow height is 50 mm higher than the console table.

4.6.4.2 The console in front of the work seat is to provide sufficient legroom to facilitate access to the equipment and control equipment to be used.

4.6.4.3 The shape of the console and the position of the display are to be designed to provide the user with the information required to perform the primary functions of the workstation within a viewing angle of 95° per side from the front.

4.6.4.4 If the seat is installed in the station used for standing and sitting operation, the seat is to be attached to the slide rail so that the seat can move back and forth to make it easy to operate the equipment while sitting, and there is enough space to stand in front of the console when the seat is pushed back, generally 700 mm. It is to be possible to adjust the height of the seat to accommodate users of different heights to obtain the best view and to achieve the best range of sight. Armrests (if provided) are to be of folding type and adjustable in height. Seats are to be equipped with adjustable trestles.

4.6.5 Passageways

4.6.5.1 The height of the entrance and door from the adjacent passageway to the wheelhouse is not to be less than 2.0 m.

4.6.5.2 At the workstation for docking, the distance between the bridge wing bulwarks, bulkheads and bridge wing consoles is to be as small as possible and the passageway is to be wide enough for one person to pass comfortably through the consoles. The width of the passageway is to be at least 600 mm.

4.6.6 Workstation for docking

4.6.6.1 The workstation for docking is to be capable of ship manoeuvring and is generally to be provided with the folloing equipment:

(1) compass display;
(2) wind speed and direction indicator;
(3) steering gear and rudder angle indicator;
(4) rotation rate indicator;
(5) controllers and indicators for main and side propulsion;
(6) BNWAS confirmation device and manual starting device;
(7) internal communication system.

Section 7 INTEGRATED BRIDGE SYSTEM (IBS)

4.7.1 General requirements

4.7.1.1 This Section applies to ships fitted with an IBS.

4.7.1.2 The layout of the IBS is to be such that the failure of one sub-system is immediately brought to the attention of the officer of the watch through auditory and visual alarms, and will not lead to the failure of any other sub-systems. If one part of an integrated navigation system (INS) fails, every other piece of equipment or every other part of the system is to be able to operate separately.

4.7.1.3 The performance criteria of the IBS is to comply with the requirements of IMO SN.1/Circ.288 Guidelines for Bridge Equipment and Systems, their Arrangement and Integration.

4.7.1.4 Ships applying for the notation BDE-3 are to comply with the requirements of this Section in addition to the applicable requirements of other sections of this Chapter.

4.7.2 Equipment

4.7.2.1 Two gyrocompasses capable of continuously displaying heading information and providing navigation equipment with corresponding input information are to be installed.
4.7.2.2 Only one gyrocompass is to be used at any time for main display and control purposes. The navigating officer is to be able to switch between compasses at any time and the non-selected compass is to be used automatically as the independent heading source for the off-course warning.
4.7.2.3 It is to be possible to compare readings from each gyrocompass via the navigation workstation displays. Automatic comparison between the compasses is to be provided and an alarm given, should the difference between heading signals exceed a pre-set value.

4.7.3 Alerts and management thereof

4.7.3.1 Navigation and operation workstations are to have a Bridge Alert Management (BAM) system that meets the requirements of IMO resolution MSC.302(87).
4.7.3.2 The BAM system is to provide the following alerts as a minimum:
(1) deviation from the route;
(2) close to the waypoint;
(3) incorrect or lost position;
(4) loss of heading input;
(5) equipment or sub-system failure;
(6) incompatibility of the compass.
4.7.3.3 Alerts are to be prioritized according to the type of emergency and response required by the navigation and operating workstations.
4.7.3.4 Within each priority, alerts will be arranged in groups to reduce the amount of information provided to the operator. However, the following alerts cannot be grouped:
(1) emergency alarm.
(2) a separate set of alarms related to a failure requiring reduction of speed or power or automatic shutdown of propulsion machinery.
(3) steering gear alarm.
(4) navigation light fault alarm.
4.7.3.5 The alerts are to be presented grouped in order of priority. Within the priorities the alerts are to be displayed in the order in which they occur (sequence). The visual display unit will provide an immediate display of new information, regardless of the currently selected information display.
4.7.3.6 Unacknowledged alerts can be distinguished by flashing text or by flashing markers adjacent to the text, not just by color changes. Acknowledged alerts can be distinguished by steady illuminated text or steady illuminated markers adjacent to the text.

CHAPTER 5 ADDITIONAL REQUIREMENTS FOR FISHING VESSELS

Section 1 GENERAL PROVISIONS

5.1.1 General requirements

5.1.1.1 The provisions of this Chapter apply to fishing vessels.

5.1.1.2 Fishing vessels complying with the Rules for Construction of Ocean-going Steel Fishing Vessels are to be assigned the Fishing Vessel class notation.

5.1.1.3 Unless expressly provided by this Chapter, fishing vessels are to comply with the relevant requirements of PART ONE of the Rules.

5.1.2 Definitions

5.1.2.1 The definitions of this Chapter are as the following:

(1) Length L_L: refers to 96% of the total length of the waterline at 85% of the minimum moulded depth on the upper edge of the keel plate, or the length along the waterline from the leading edge of the bow to the center of the rudder stock, whichever is greater. For fishing vessels without rudder stock, the length L_L is taken as 96% of the total length of the waterline at 85% of the smallest depth. If the shape of the bow above the waterline at the minimum depth of 85% is concave, the foremost end of the total length and the front edge of the bow shall be measured from the point where the last point of the shape of the bow above the waterline is projected vertically on the waterline (see figure 5.1.2.1-1).For fishing vessels whose keel is designed to be inclined, the waterline for measuring this length should be parallel to the design waterline at 85% of the minimum moulded depth D_{min}. The waterline is obtained by drawing a tangent line parallel to the keel line of the fishing vessel and tangent to the depth arc of the working deck in the figure below. In this case, the minimum depth is the vertical distance measured from the upper edge of the keel plate to the upper side of the beam at the side of the working deck at the tangent point (see figure 5.1.2.1-2).

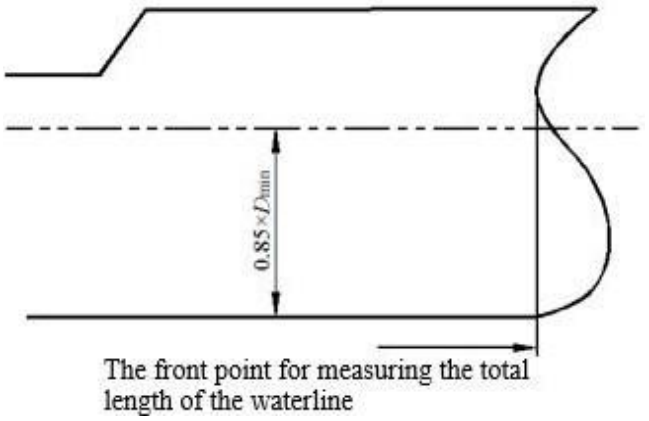

Figure 5.1.2.1-1 The front point for measuring the total length of the waterline, for fishing vessels with recessed bow shape.

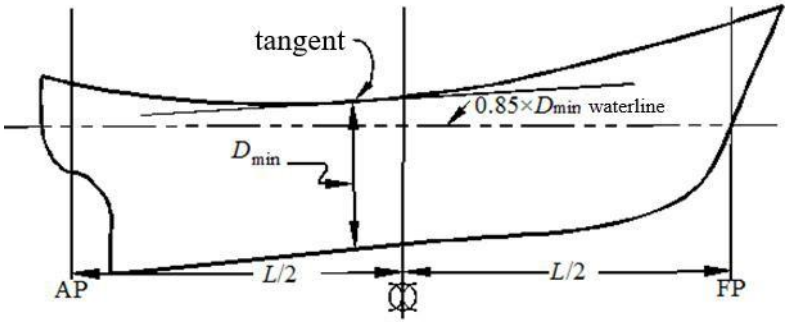

Figure 5.1.2.1-2 The length of a leaning keel fishing vessel

(2) Keel line: refers to the line that passes through the following specific points in the vessel and is parallel to the slope of the keel: for metal hull fishing vessels, it is the line of the upper edge of the keel or the line of intersection between the inner edge of the hull plate and the keel; if there is a bar keel, then it is the intersection point between the bar keel extension line and the inner side of the hull plate. For non-metallic fishing vessels, it is the intersection of the respective extension lines of the outer surface of the bottom and the outer surface of the bar keel; if there is no bar keel, it is the bottom point.
(3) Breadth B: refers to the maximum width in a fishing vessel. For a metal shell, the breadth is measured at the midship to the inner surface of the hull; for a fishing vessel with other material shells, the breadth is measured at the midship to the outer surface of the hull.
(4) Depth D: the vertical distance measured from the upper edge of the keel plate to the upper edge of the beam at the side of the working deck. For fishing vessels with wooden and mixed material structures, the vertical distance is measured from the lower edge of the keel notch. If the shape of the lower part of the midship section is concave, or when thickened keel wing panels are installed, the vertical distance is measured from the point where the inward extension line of the flat part of the bottom of the ship intersects with the side of the keel. If the working deck is stepped and its raised part extends beyond the point that determines the moulded depth, the moulded depth shall be measured to the extended dashed line of the lower part of the deck, which is parallel to the raised part of the deck. If there are no special regulations, it generally refers to the depth of the middle of the ship.
(5) Working deck: is generally the lowest complete deck above the deepest operating waterline from which fishing is undertaken. In vessels fitted with two or more complete decks, the lower deck as a working deck provided that the deck is situated above the deepest operating waterline.
Where the lowest complete deck above the deepest operating waterline is stepped, the lowest line of the deck and the continuation of that line parallel to the upper part of the deck is taken as the working deck.
Discontinuous working deck, stepped working deck,

① Where a recess in the working deck does not extend to the sides of the ship, the upper part of the deck is taken as the working deck (see figure 5.1.2.1-3).
② Recesses not extending from side to side in a deck below the exposed deck, designated as the working deck, may be disregarded, provided all openings in the weather deck are fitted with weathertight closing appliances.
③ Recesses not extending from side to side in a deck below the exposed deck, designated as the working deck, may be disregarded, provided all openings in the weather deck are fitted with weathertight closing appliances.

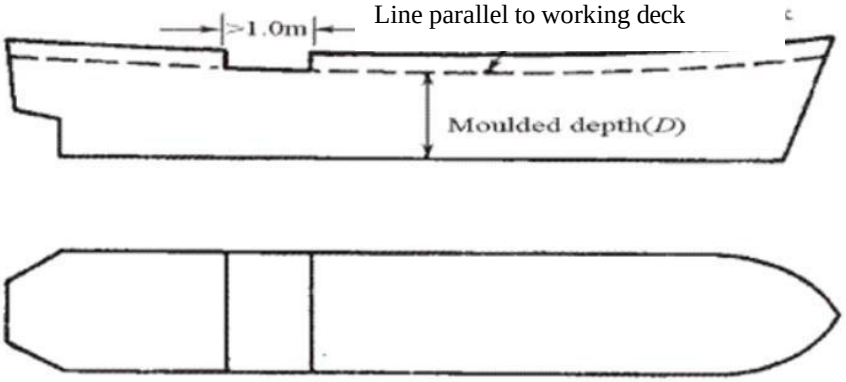

Figure 5.1.2.1-3 the working deck of a recess

Section 2 SURVEYS DURING CONSTRUCTION

5.2.1 Requirements for surveys and tests of fishing vessels

5.2.1.1 Unless expressly provided by this Section, surveys and tests of fishing vessels are to comply with the provisions of Sections 1 and 2, Chapter 4, PART ONE of the Rules.
5.2.1.2 Unless expressly provided by the flag State, the list of certification for statutory products of fishing vessels is to comply with the relevant requirements of Chapter 3 , PART ONE of the Rules.

5.2.1.3 Tests of fishing vessels are to comply with the requirements of 4.2.3, Section 2, Chapter 4, PART ONE of the Rules, except that 4.2.3.3(3) is not applicable. The tightness tests of compartments are to comply with the requirements of Part B, Annex 1, Section 3, Chapter 4, PART ONE of the Rules.
